When you configure separate undo log tablespaces, you can also configure the separate undo log tablespaces to go to a specific directory by setting the innodb_undo_directory system variable. This is most helpful if you want to put the undo log tablespaces on a separate storage device.

Separate InnoDB undo log tablespaces must be configured prior to the initialization of the server's InnoDB data directory. If you try to configure separate InnoDB undo log tablespaces when the InnoDB data directory has already been initializes, you will see errors in the error log during startup similar to the following:

```
[ERROR] InnoDB: Expected to open innodb_undo_tablespaces=8 but was able to find only 0
[ERROR] InnoDB: Plugin initialization aborted with error Generic error
```

To safely configure separate InnoDB undo log tablespaces:

1. If you have preexisting data, backup your data with MariaDB Dump.
2. Ensure that the server is stopped:

```
$ sudo systemctl stop mariadb
```

3. Choose a configuration file for custom changes to system variables and options.

It is not recommended to make custom changes to Enterprise Server's default configuration files, because your custom changes can be overwritten by other default configuration files that are loaded after.

Ensure that your custom changes are read last by creating a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. Ensure that your custom configuration file is read last by using the `z-` prefix in the file name.

Some example configuration file paths for different distributions are shown in the following table:

Distributions	Example configuration file path
CentOS RHEL Rocky Linux SLES	/etc/my.cnf.d/z-custom-mariadb.cnf
Debian Ubuntu	/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf

4. Set the innodb_undo_tablespaces system variable in the configuration file.

It needs to be set in a group that are read by MariaDB Server, such as [mariadb] or [server].

For example, to set the number of tablespaces to 8:

```
[mariadb]
...
innodb_undo_tablespaces=8
```

5. If you want your InnoDB undo log tablespaces to be in a specific directory, then also set the innodb_undo_directory system variable in the configuration file:

For example, to set the directory to /innodb/undo:

```
[mariadb]
...
innodb_undo_directory=/innodb/undo
```

6. If you want your InnoDB undo log tablespaces to be in a specific directory, then also create the directory, and give it the proper permissions:

```
$ sudo mkdir -p /innodb/undo
$ sudo chown mysql:mysql /innodb/undo
```

7. Delete the current contents of the datadir and innodb_data_home_dir.

For example, if the default value of /var/lib/mysql is used for both:

```
$ sudo rm -fr /var/lib/mysql/*
```

8. Reinitialize the data directory using the MariaDB Install DB command.
9. Start the server:

```
$ sudo systemctl start mariadb
```

10. Connect to the server using MariaDB Client:

```
$ mariadb --user=root
```

11. If your server had preexisting data, then reload the backup taken at the beginning of the procedure.
12. Confirm that the configuration changes were properly applied by checking the values of the system variables using the SHOW GLOBAL VARIABLES statement:

```
SHOW GLOBAL VARIABLES
   WHERE Variable_name IN (
      'innodb_undo_tablespaces',
      'innodb_undo_directory'
   );
```

```
+-------------------------+--------------+
| Variable_name           | Value        |
+-------------------------+--------------+
| innodb_undo_directory   | /innodb/undo |
| innodb_undo_tablespaces | 8            |
+-------------------------+--------------+
```

13. Consider also enabling undo log truncation to increase performance of the InnoDB Purge Threads.

Enable InnoDB Undo Log Truncation

If a server is configured to have 2 or more separate InnoDB undo log files, then InnoDB undo log truncation can be enabled by setting the innodb_undo_log_truncate system variable using the SET GLOBAL statement. The SET GLOBAL statement requires the SUPER privilege.

When InnoDB undo log truncation is enabled, the InnoDB purge threads can truncate an entire undo log at once, rather than individually freeing each rollback segment within the undo log.

An undo log is truncated when its size exceeds the innodb_max_undo_log_size system variable.

The frequency at which the InnoDB purge threads check for undo logs to truncate is configured by setting the innodb_purge_rseg_truncate_frequency system variable using the SET GLOBAL statement.

To ensure that the changes survive server restarts, the system variables should also be set in a configuration file.

To enable InnoDB undo log truncation:

1. Connect to the server using MariaDB Client as the `root@localhost` user account or another user account with the SUPER privilege:

```
$ mariadb --user=root
```

2. Set the innodb_undo_log_truncate system variable to ON using the SET GLOBAL statement.

For example:

```
SET GLOBAL innodb_undo_log_truncate=ON;
```

3. If you would like to change the size at which undo logs are truncated, then also set the innodb_max_undo_log_size system variable to the new size using the SET GLOBAL statement.

For example, to set the size to 2 GB:

```
SET GLOBAL innodb_max_undo_log_size=(2 * 1024 * 1024 * 1024);
```

4. If you would like the InnoDB purge threads to check the undo logs more frequently, then also set the innodb_purge_rseg_truncate_frequency system variable to a lower value using the SET GLOBAL statement.

For example, to configure the purge threads to check the undo logs for truncation every 64 iterations:

```
SET GLOBAL innodb_purge_rseg_truncate_frequency=64;
```

5. Choose a configuration file for custom changes to system variables and options.
   It is not recommended to make custom changes to Enterprise Server's default configuration files, because your custom changes can be overwritten by other default configuration files that are loaded after.

Ensure that your custom changes are read last by creating a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. Ensure that your custom configuration file is read last by using the `z-` prefix in the file name.

Some example configuration file paths for different distributions are shown in the following table:

Distributions	Example configuration file path
CentOS RHEL Rocky Linux SLES	/etc/my.cnf.d/z-custom-mariadb.cnf
Debian Ubuntu	/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf

6. Set the system variables in the configuration file.
   It needs to be set in a group that are read by MariaDB Server, such as [mariadb] or [server].
   When set in a configuration file, the innodb_max_undo_log_size value supports units, such as "M", "G", etc.

For example:

```
[mariadb]
...
innodb_undo_log_truncate=ON
innodb_max_undo_log_size=2G
innodb_purge_rseg_truncate_frequency=64
```

Schema Changes

Overview

In MariaDB Enterprise Server, InnoDB supports many different schema change operations. Many of the operations can be performed online with concurrent DML using little or no locking.

DDL Statements

InnoDB schema changes are performed using the following DDL statements:

- ALTER TABLE
- CREATE INDEX
- CREATE SPATIAL INDEX
- CREATE UNIQUE INDEX
- DROP INDEX
- RENAME TABLE

About InnoDB Schema Changes and Online DDL

InnoDB schema changes and online DDL are performed with a wide range of statements:

Each operation supports a subset of the following algorithms: `INSTANT, NOCOPY, INPLACE, or COPY`.

By default, InnoDB will use the most efficient algorithm supported by an operation. This behavior can be changed by using the `ALGORITHM` clause with the ALTER TABLE statement or by changing the value of the alter_algorithm system variable.

Each operation supports a subset of the following locking strategies: `NONE, SHARED, or EXCLUSIVE`.

By default, InnoDB will use the most permissive locking strategy supported by an operation. This behavior can be changed by using the LOCK clause with the ALTER TABLE statement.

Feature	Detail	Resources
Operations support instant algorithm	Yes	InnoDB Schema Changes with the INSTANT Algorithm
Operations support no-copy algorithm	Yes	InnoDB Schema Changes with the NOCOPY Algorithm
Operations support in-place algorithm	Yes	InnoDB Schema Changes with the INPLACE Algorithm
Adding a column	Yes	
Dropping a column	Yes	
Reordering columns	Yes	
Changing a column to NULL	Yes	
Changing a column to NOT NULL	Yes	
Adding a new ENUM option	Yes	
Adding a new SET option	Yes	
Adding system versioning	Yes	
Removing system versioning	Yes	
Setting a column's DEFAULT	Yes	
Removing a column's DEFAULT	Yes	
Adding a primary key	Yes	
Dropping a primary key	Yes	
Adding an index	Yes	
Dropping an index	Yes	
Adding a foreign key	Yes	
Dropping a foreign key	Yes	
Setting the next AUTO_INCREMENT value	Yes	
Setting the row format	Yes	
Setting the block size for the Compressed row format	Yes	
Enabling page compression	Yes	

Feature	Detail	Resources
Setting the page compression level	Yes	
Disabling page compression	Yes	
Enabling data-at-rest encryption	Yes	
Setting the encryption key ID	Yes	
Disabling data-at-rest encryption	Yes	
Adding a constraint	Yes	
Dropping a constraint	Yes	
Rebuilding the table	Yes	
Renaming the table	Yes

InnoDB Schema Changes

MariaDB Enterprise Server InnoDB Schema Changes with the INPLACE Algorithm

Changes in enterprise databases and applications are inevitable. Schema changes often block other workloads, incur unique production situations that cannot be fully simulated for testing, and may have unpredictable execution times.

MariaDB Enterprise Server includes the In-place `ALTER` functionality for the InnoDB storage engine, such that:

When possible, schema change operations are performed `INPLACE`, minimizing impact on other workloads.

When the `alter_algorithm` system variable is set to `INPLACE`, schema change operations will not run unless they can be performed `INPLACE`, minimizing the risk of unpredictable behavior.

Additional information is available here.

MariaDB Enterprise Server InnoDB Schema Changes with the INSTANT Algorithm

Changes in enterprise databases and applications are inevitable. Schema changes often block other workloads, incur unique production situations that cannot be fully simulated for testing, and may have unpredictable execution times.

MariaDB Enterprise Server includes the Instant `ALTER` functionality for the InnoDB storage engine, such that:

When possible, schema change operations are performed `INSTANT`, minimizing impact on other workloads.

When the `alter_algorithm` system variable is set to `INSTANT`, schema change operations will not run unless they can be performed `INSTANT`, minimizing the risk of unpredictable behavior.

Additional information is available here.

MariaDB Enterprise Server InnoDB Schema Changes with the NOCOPY Algorithm

Changes in enterprise databases and applications are inevitable. Schema changes often block other workloads, incur unique production situations that cannot be fully simulated for testing, and may have unpredictable execution times.

MariaDB Enterprise Server includes the No-copy `ALTER` functionality for the InnoDB storage engine, such that:

When possible, schema change operations are performed `NOCOPY`, minimizing impact on other workloads.

When the alter_algorithm system variable is set to `NOCOPY`, schema change operations will not run unless they can be performed `NOCOPY`, minimizing the risk of unpredictable behavior.

Additional information is available here.

About XtraDB

Percona XtraDB was an enhanced version of the InnoDB storage engine used in MariaDB before MariaDB 10.2, designed to better scale on modern hardware, and it includes a variety of other features useful in high-performance environments.

It is fully backwards compatible, and it identifies itself to MariaDB as "`ENGINE=InnoDB`" (just like InnoDB), and so can be used as a drop-in replacement for standard InnoDB.

Percona XtraDB includes all of InnoDB's robust, reliable ACID-compliant design and advanced MVCC architecture, and builds on that solid foundation with more features, more tunability, more metrics, and more scalability. In particular, it is designed to scale better on many cores, to use memory more efficiently, and to be more convenient and useful. The new features are especially designed to alleviate some of InnoDB's limitations. We choose features and fixes based on customer requests and on our best judgment of real-world needs as a high-performance consulting company.

XtraDB was also available in MariaDB for Windows.

Percona XtraDB versions in MariaDB

MariaDB 10.1

- XtraDB from Percona Server 5.6.49-89.0 in MariaDB 10.1.46
- XtraDB from Percona Server 5.6.46-86.2 in MariaDB 10.1.44
- XtraDB from Percona Server 5.6.43-84.3 in MariaDB 10.1.39
- XtraDB from Percona Server 5.6.41-84.1 in MariaDB 10.1.36
- XtraDB from Percona Server 5.6.38-83.0[1] in MariaDB 10.1.31
- XtraDB from Percona Server 5.6.37-82.2[2]in MariaDB 10.1.27
- XtraDB from Percona Server 5.6.36-82.1 in MariaDB 10.1.26
- XtraDB from Percona Server 5.6.36-82.0 in MariaDB 10.1.24
- XtraDB from Percona Server 5.6.35-80.0 in MariaDB 10.1.22
- XtraDB from Percona Server 5.6.34-79.1 in MariaDB 10.1.20
- XtraDB from Percona Server 5.6.33-79.0[3] in MariaDB 10.1.19
- XtraDB from Percona Server 5.6.32-78.1 in MariaDB 10.1.18
- XtraDB from Percona Server 5.6.31-77.0 in MariaDB 10.1.17
- XtraDB from Percona Server 5.6.30-76.3 in MariaDB 10.1.15
- XtraDB from Percona Server 5.6.29-76.2 in MariaDB 10.1.14

- XtraDB from Percona Server 5.6.28-76.1 in MariaDB 10.1.12
- XtraDB from Percona Server 5.6.26-76.0 in MariaDB 10.1.10
- XtraDB from Percona Server 5.6.26-74.0 in MariaDB 10.1.8
- XtraDB from Percona Server 5.6.25-73.1 in MariaDB 10.1.7
- XtraDB from Percona Server 5.6.24-72.2 in MariaDB 10.1.6
- XtraDB from Percona Server 5.6.23-72.1 in MariaDB 10.1.5
- XtraDB from Percona Server 5.6.22-72.0 in MariaDB 10.1.4
- XtraDB from Percona Server 5.6.21-70.0 in MariaDB 10.1.2
- XtraDB from Percona Server 5.6.17-65.0 in MariaDB 10.1.1

MariaDB 10.0

- XtraDB from Percona Server 5.6.42-84.2 in MariaDB 10.0.38
- XtraDB from Percona Server 5.6.41-84.1 in MariaDB 10.0.37
- XtraDB from Percona Server 5.6.39-83.1 in MariaDB 10.0.35
- XtraDB from Percona Server 5.6.38-83.0[4]in MariaDB 10.0.34
- XtraDB from Percona Server 5.6.37-82.2[5]in MariaDB 10.0.33
- XtraDB from Percona Server 5.6.36-82.1 in MariaDB 10.0.32
- XtraDB from Percona Server 5.6.36-82.0 in MariaDB 10.0.31
- XtraDB from Percona Server 5.6.35-80.0 in MariaDB 10.0.30
- XtraDB from Percona Server 5.6.34-79.1 in MariaDB 10.0.29
- XtraDB from Percona Server 5.6.33-79.0[6] in MariaDB 10.0.28
- XtraDB from Percona Server 5.6.31-77.0 in MariaDB 10.0.27
- XtraDB from Percona Server 5.6.30-76.3 in MariaDB 10.0.26
- XtraDB from Percona Server 5.6.29-76.2 in MariaDB 10.0.25
- XtraDB from Percona Server 5.6.28-76.1 in MariaDB 10.0.24
- XtraDB from Percona Server 5.6.27-76.0 in MariaDB 10.0.23
- XtraDB from Percona Server 5.6.26-74.0 in MariaDB 10.0.22
- XtraDB from Percona Server 5.6.25-73.1 in MariaDB 10.0.21
- XtraDB from Percona Server 5.6.24-72.2 in MariaDB 10.0.20
- XtraDB from Percona Server 5.6.23-72.1 in MariaDB 10.0.18
- XtraDB from Percona Server 5.6.22-72.0 in MariaDB 10.0.17
- XtraDB from Percona Server 5.6.22-71.0 in MariaDB 10.0.16
- XtraDB from Percona Server 5.6.21-70.0 in MariaDB 10.0.15
- XtraDB from Percona Server 5.6.20-68.0 in MariaDB 10.0.14
- XtraDB from Percona Server 5.6.19-67.0 in MariaDB 10.0.13
- XtraDB from Percona Server 5.6.17-65.0 in MariaDB 10.0.11
- XtraDB from Percona Server 5.6.14-rel62.0 in MariaDB 10.0.7

MariaDB 5.5

- XtraDB from Percona Server 5.5.61-38.13 in MariaDB 5.5.62
- XtraDB from Percona Server 5.5.59-38.11 in MariaDB 5.5.60
- XtraDB from Percona Server 5.5.58-38.10 in MariaDB 5.5.59
- XtraDB from Percona Server 5.5.55-38.9 in MariaDB 5.5.58
- XtraDB from Percona Server 5.5.55-38.8 in MariaDB 5.5.57
- XtraDB from Percona Server 5.5.52-38.3 in MariaDB 5.5.53

- XtraDB from Percona Server 5.5.50-38.0 in MariaDB 5.5.51
- XtraDB from Percona Server 5.5.49-37.9 in MariaDB 5.5.50
- XtraDB from Percona Server 5.5.48-37.8 in MariaDB 5.5.49
- XtraDB from Percona Server 5.5.46-37.7 in MariaDB 5.5.48
- XtraDB from Percona Server 5.5.46-37.6 in MariaDB 5.5.47
- XtraDB from Percona Server 5.5.45-37.4 in MariaDB 5.5.46
- XtraDB from Percona Server 5.5.44-37.3 in MariaDB 5.5.45
- XtraDB from Percona Server 5.5.42-37.2 in MariaDB 5.5.44
- XtraDB from Percona Server 5.5.42-37.1 in MariaDB 5.5.43
- XtraDB from Percona Server 5.5.40-36.1 in MariaDB 5.5.40
- XtraDB from Percona Server 5.5.38-35.2 in MariaDB 5.5.39
- XtraDB from Percona Server 5.5.37-35.0 in MariaDB 5.5.38
- XtraDB from Percona Server 5.5.36-34.0 in MariaDB 5.5.37
- XtraDB from Percona Server 5.5.35-33.0 in MariaDB 5.5.35
- XtraDB from Percona Server 5.5.34-32.0 in MariaDB 5.5.34
- XtraDB from Percona Server 5.5.33-31.1 in MariaDB 5.5.33
- XtraDB from Percona Server-5.5.32-31.0 in MariaDB 5.5.32

MariaDB 5.2 and MariaDB 5.3

- MariaDB 5.2 and 5.3 include the latest XtraDB version from MariaDB 5.1 at the time they were released.

MariaDB 5.1

- version 5.1.59-13 in MariaDB 5.1.60
- version 5.1.54-12.5 in MariaDB 5.1.55
- version 5.1.52-11.6 in MariaDB 5.2.4 and 5.1.53
- version 5.1.49-12 in MariaDB 5.1.50
- version 5.1.47-11.2 in MariaDB 5.1.49
- version 1.0.6-10 in MariaDB 5.1.47
- version 1.0.6-9 in MariaDB 5.1.42,5.1.44, and 5.1.44b.
- version 1.0.4-8 in MariaDB 5.1.41 RC
- version 1.0.3-8 in MariaDB 5.1.39 Beta
- version 1.0.3-6 in MariaDB 5.1.38 Beta

Notes

1. ↑ Misidentifies itself as 5.6.36-83.0 in MariaDB 10.1.31
2. ↑ Misidentifies itself as 5.6.36-82.2 from MariaDB 10.1.27 to MariaDB 10.1.30
3. ↑ Misidentifies itself as 5.6.32-79.0 in MariaDB 10.1.19
4. ↑ Misidentifies itself as 5.6.36-83.0 in MariaDB 10.0.34
5. ↑ Misidentifies itself as 5.6.36-82.2 in MariaDB 10.0.33
6. ↑ Misidentifies itself as 5.6.32-79.0 in MariaDB 10.0.28

Using InnoDB Instead of XtraDB

XtraDB, previously the default InnoDB replacement in MariaDB, is no longer included in standard distributions. MariaDB now uses InnoDB by default.

The reasons you may want to use InnoDB instead of XtraDB in earlier versions of MariaDB are:

- You want to benchmark the difference between InnoDB/XtraDB
- You hit a bug in XtraDB
- You got a table space crash in XtraDB and recovery doesn't work. In some cases InnoDB may do a better job to recover data.

MEMORY

Contents of the MEMORY storage engine (previously known as HEAP) are stored in memory rather than on disk.

It is best-used for read-only caches of data from other tables, or for temporary work areas.

Since the data is stored in memory, it is highly vulnerable to power outages or hardware failure, and is unsuitable for permanent data storage. In fact, after a server restart, `MEMORY` tables are recreated (because the definition file is stored on disk), but they are empty. It is possible to re-populate them with a query using the `--init-file` server startup option.

Variable-length types like VARCHAR can be used in MEMORY tables. BLOB or TEXT columns are not supported for MEMORY tables.

Memory Usage

The maximum total size of MEMORY tables cannot exceed the max_heap_table_size system server variable. When a table is created this value applies to that table, and when the server is restarted this value applies to existing tables. Changing this value has no effect on existing tables. However, executing a `ALTER TABLE ... ENGINE=MEMORY` statement applies the current value of `max_heap_table_size` to the table. Also, it is possible to change the session value of `max_heap_table_size` before creating a table, to make sure that tables created by other sessions are not affected.

The `MAX_ROWS` table option provides a hint about the number of rows you plan to store in them. This is not a hard limit that cannot be exceeded, and does not allow to exceed `max_heap_table_size`. The storage engine uses max_heap_table_size and MAX_ROWS to calculate the maximum memory that could be allocated for the table.

Memory allocated to a MEMORY table is freed by running DROP TABLE or TRUNCATE TABLE, or rebuilding with ALTER TABLE tbl_name ENGINE = MEMORY. When rows are deleted, space is not automatically freed.

Replication

The data in MEMORY tables are lost when a server restarts. To reflect this result in replication, the first time a server uses a MEMORY table after a restart, it writes a TRUNCATE statement for that table with a "generated by server" comment to the binary log, so its replicas are also emptied.

> **Warning:**
>
> In non-circular replication, restarting a replica will diverge from its primaries in both MEMORY table data and GTID. The contents and replication must be resynchronized to fix this issue. Alternatively, if consistency is not required (e.g., for cache data), then the replica should have a different Domain ID than its primaries to satisfy GTID strict mode.
>
> If the MEMORY tables are not required for replication at all, then excluding them from replication avoids this problem entirely.

Index Type

The MEMORY storage engine permits indexes to be either B-tree or Hash. Hash is the default type for MEMORY. See Storage Engine index types for more on their characteristics.

A MEMORY table can have up to 64 indexes, 16 columns for each index and a maximum key length of 3072 bytes.

Example

The following example shows how to create a `MEMORY` table with a given maximum size, as described above.

```
SET max_heap_table_size = 1024*516;

CREATE TABLE t (a VARCHAR(10), b INT) ENGINE = MEMORY;

SET max_heap_table_size = @@max_heap_table_size;
```

MERGE

Description

The MERGE storage engine, also known as the MRG_MyISAM engine, is a collection of identical MyISAM tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with myisampack. Columns names and indexes names can be different, as long as data types and `NULL` / `NOT NULL` clauses are the same. Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

Each index in a `MERGE` table must match an index in underlying `MyISAM` tables, but the opposite is not true. Also, a `MERGE` table cannot have a `PRIMARY KEY` or `UNIQUE` indexes, because it cannot enforce uniqueness over all underlying tables.

The following options are meaningful for `MERGE` tables:

- `UNION`. This option specifies the list of the underlying `MyISAM` tables. The list is enclosed between parentheses and separated with commas.
- `INSERT_METHOD`. This options specifies whether, and how, `INSERT`s are allowed for the table. Allowed values are: `NO` (`INSERT`s are not allowed), `FIRST` (new rows are written into the first table specified in the `UNION` list), `LAST` (new rows are written into the last table specified in the `UNION` list). The default value is `NO`.

If you define a `MERGE` table with a definition which is different from the underlying `MyISAM` tables, or one of the underlying tables is not `MyISAM`, the `CREATE TABLE` statement will not return any error. But any statement which involves the table will produce an error like the following:

```
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
  or of non-MyISAM type or doesn't exist
```

A CHECK TABLE will show more information about the problem.

The error is also produced if the table is properly define, but an underlying table's definition changes at some point in time.

If you try to insert a new row into a `MERGE` table with `INSERT_METHOD=NO`, you will get an error like the following:

```
ERROR 1036 (HY000): Table 'tbl_name' is read only
```

It is possible to build a `MERGE` table on `MyISAM` tables which have one or more virtual columns. `MERGE` itself does not support virtual columns, thus such columns are seen as regular columns. The data types and sizes will still need to be identical, and they cannot be `NOT NULL`.

Examples

```
CREATE TABLE t1 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20)) ENGINE=MyISAM;

CREATE TABLE t2 (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    message CHAR(20)) ENGINE=MyISAM;

INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');

INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');

CREATE TABLE total (
    a INT NOT NULL AUTO_INCREMENT,
    message CHAR(20), INDEX(a))
    ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;

SELECT * FROM total;
+---+---------+
| a | message |
+---+---------+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+---------+
```

In the following example, we'll create three `MyISAM` tables, and then a `MERGE` table on them. However, one of them uses a different data type for the column b, so a `SELECT` will produce an error:

```
CREATE TABLE t1 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t2 (
  a INT,
  b INT
) ENGINE = MyISAM;

CREATE TABLE t3 (
  a INT,
  b TINYINT
) ENGINE = MyISAM;

CREATE TABLE t_mrg (
  a INT,
  b INT
) ENGINE = MERGE,UNION=(t1,t2,t3);

SELECT * FROM t_mrg;
ERROR 1168 (HY000): Unable to open underlying table which is differently defined
 or of non-MyISAM type or doesn't exist
```

To find out what's wrong, we'll use a `CHECK TABLE`:

```
CHECK TABLE t_mrg\G
*************************** 1. row ***************************
   Table: test.t_mrg
      Op: check
Msg_type: Error
Msg_text: Table 'test.t3' is differently defined or of non-MyISAM type or doesn't exist
*************************** 2. row ***************************
   Table: test.t_mrg
      Op: check
Msg_type: Error
Msg_text: Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't
exist
*************************** 3. row ***************************
   Table: test.t_mrg
      Op: check
Msg_type: error
Msg_text: Corrupt
```

Now, we know that the problem is in `t3`'s definition.

Extend Mroonga's functionality in MariaDB Server with user-defined functions. Learn how to create custom functions to enhance full-text search and data processing capabilities.

This page is licensed: CC BY-SA / Gnu FDL

Mroonga Overview

Once Mroonga has been installed (see About Mroonga), its basic usage is similar to that of a regular fulltext index.

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy)) ENGINE=Mroonga;

INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
    ('There was a wicked witch'), ('Who ate everybody up');

SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('wicked');
+--------------------------+
| copy                     |
+--------------------------+
| There was a wicked witch |
+--------------------------+
```

Score

Mroonga can also order by weighting. For example, first add another record:

```
INSERT INTO ft_mroonga(copy) VALUES ('She met a wicked, wicked witch');
```

Records can be returned by weighting, for example, the newly added record has two occurrences of the word 'wicked' and a higher weighting:

```
SELECT *, MATCH(copy) AGAINST('wicked') AS score FROM ft_mroonga
   WHERE MATCH(copy) AGAINST('wicked') ORDER BY score DESC;
+--------------------------------+--------+
| copy                           | score  |
+--------------------------------+--------+
| She met a wicked, wicked witch | 299594 |
| There was a wicked witch       | 149797 |
+--------------------------------+--------+
```

Parser

Mroonga permits you to set a different parser for searching by specifying the parser in the `CREATE TABLE` statement as a comment or, in older versions, changing the value of the mroonga_default_parser system variable.

For example:

```
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenDelimitNull"')
  ENGINE=Mroonga;,
```

or

```
SET GLOBAL mroonga_default_parser = 'TokenBigramSplitSymbol';
```

The following parser settings are available:

Setting	Description
off	No tokenizing is performed.
TokenBigram	Default value. Continuous alphabetical characters, numbers or symbols are treated as a token.
TokenBigramIgnoreBlank	Same as TokenBigram except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbol	Same as TokenBigramSplitSymbol. except that white spaces are ignore.
TokenBigramIgnoreBlankSplitSymbolAlpha	Same as TokenBigramSplitSymbolAlpha except that white spaces are ignored.
TokenBigramIgnoreBlankSplitSymbolAlphaDigit	Same as TokenBigramSplitSymbolAlphaDigit except that white spaces are ignored.
TokenBigramSplitSymbol	Same as TokenBigram except that continuous symbols are not treated as a token, but tokenised in bigram.
TokenBigramSplitSymbolAlpha	Same as TokenBigram except that continuous alphabetical characters are not treated as a token, but tokenised in bigram.
TokenDelimit	Tokenises by splitting on white spaces.
TokenDelimitNull	Tokenises by splitting on null characters (\0).
TokenMecab	Tokenise using MeCab. Required Groonga to be built with MeCab support.
TokenTrigram	Tokenises in trigrams but continuous alphabetical characters, numbers or symbols are treated as a token.
TokenUnigram	Tokenises in unigrams but continuous alphabetical characters, numbers or symbols are treated as a token.

Examples

TokenBigram vs TokenBigramSplitSymbol

`TokenBigram` failing to match partial symbols which `TokenBigramSplitSymbol` matches, since `TokenBigramSplitSymbol` does not treat continuous symbols as a token.

```
DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"')
  ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'),
  ('Who ate everybody up'),
  ('She met a wicked, wicked witch'),
  ('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbol"')
  ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'),
  ('Who ate everybody up'),
  ('She met a wicked, wicked witch'),
  ('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('!?');
+----------------------------------+
| copy                             |
+----------------------------------+
| A really wicked, wicked witch!!?! |
+----------------------------------+
```

TokenBigram vs TokenBigramSplitSymbolAlpha

```
DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigram"')
  ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'),
  ('Who ate everybody up'),
  ('She met a wicked, wicked witch'),
  ('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
Empty set (0.00 sec)

DROP TABLE ft_mroonga;
CREATE TABLE ft_mroonga(copy TEXT,FULLTEXT(copy) COMMENT 'parser "TokenBigramSplitSymbolAlpha"')
  ENGINE=Mroonga;
INSERT INTO ft_mroonga(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'),
  ('Who ate everybody up'),
  ('She met a wicked, wicked witch'),
  ('A really wicked, wicked witch!!?!');
SELECT * FROM ft_mroonga WHERE MATCH(copy) AGAINST('ick');
+----------------------------------+
| copy                             |
+----------------------------------+
| There was a wicked witch         |
| She met a wicked, wicked witch   |
| A really wicked, wicked witch!!?! |
+----------------------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

About Mroonga

Mroonga is a full-text search storage engine based on Groonga, which is an open-source CJK-ready (Chinese, Japanese, and Korean) fulltext search engine using column base. See groonga.org for more.

With Mroonga, you can have a CJK-ready full text search feature, and it is faster than the MyISAM and InnoDB full text search for both updating and searching.

Mroonga also supports Groonga's fast geolocation search by using MariaDB's geolocation SQL syntax.

Mroonga only supports Linux x86_64 (Intel64/AMD64).

How to Install

Enable Mroonga with the following statement:

```
INSTALL SONAME 'ha_mroonga';
```

On Debian and Ubuntu mroonga engine are installed with

```
sudo apt-get install mariadb-plugin-mroonga
```

See Plugin overview for details on installing and uninstalling plugins.

SHOW ENGINES can be used to check whether Mroonga is installed correctly:

```
SHOW ENGINES;
...
*************************** 8. row ***************************
      Engine: Mroonga
     Support: YES
     Comment: CJK-ready fulltext search, column store
Transactions: NO
          XA: NO
  Savepoints: NO
...
```

Once the plugin is installed, add a UDF (User-Defined Function) named "last_insert_grn_id", that returns the record ID assigned by groonga in INSERT, by the following SQL.

```
CREATE FUNCTION last_insert_grn_id RETURNS INTEGER SONAME 'ha_mroonga.so';
```

Limitations

- The maximum size of a single key is 4096 bytes.
- The maximum size of all keys is 4GB.
- The maximum number of records in a fulltext index is 268,435,455
- The maximum number of distinct terms in a fulltext index is 268,435,455
- The maximum size of a fulltext index is 256GB

Note that the maximum sizes are not hard limits, and may vary according to circumstance.

For more details, see limitations.html.

Available Character Sets

Mroonga supports a limited number of character sets. These include:

- ASCII
- BINARY
- CP932
- EUCJPMS
- KOI8R
- LATIN1
- SJIS
- UJIS

- UTF8
- UTF8MB4

More Information

Further documentation for Mroonga can be found at

This page is licensed: CC BY-SA / Gnu FDL

Mroonga Status Variables

This page documents status variables related to the Mroonga storage engine. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

`Mroonga_count_skip`

- Description: Incremented each time the 'fast line count feature' is used. Can be used to check if the feature is working after enabling it.
- Data Type: `numeric`

`Mroonga_fast_order_limit`

- Description: Incremented each time the 'fast ORDER BY LIMIT feature' is used. Can be used to check if the feature is working after enabling it.
- Data Type: `numeric`

This page is licensed: CC BY-SA / Gnu FDL

Mroonga System Variables

This page documents system variables related to the Mroonga storage engine. See Server System Variables for instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

`mroonga_action_on_fulltext_query_error`

- Description: Action to take when encountering a Mroonga fulltext error.
  - `ERROR`: Report an error without logging.
  - `ERROR_AND_LOG`: Report an error with logging (the default)
  - `IGNORE`: No logging or reporting - the error is ignored.
  - `IGNORE_AND_LOG`: Log the error without reporting it.
- Command line: `--mroonga-action-on-fulltext-query-error=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `ERROR_AND_LOG`

`mroonga_boolean_mode_syntax_flags`

- Description: Flags to customize syntax in BOOLEAN MODE searches. Available flags:
  - `DEFAULT`: (=SYNTAX_QUERY,ALLOW_LEADING_NOT)
  - `ALLOW_COLUMN`: Allows `COLUMN:...` syntax in query syntax, an incompatible change to the regular BOOLEAN MODE syntax. Permits multiple indexes in one `MATCH () AGAINST ()`. Can be used in other

operations besides full-text search, such as equal, and prefix search. See Groonga query syntax for more details.
    - `ALLOW_LEADING_NOT` Permits using the `NOT_INCLUDED_KEYWORD` syntax in the query syntax.
    - `ALLOW_UPDATE`: Permits updating values with the `COLUMN:=NEW_VALUE` syntax in the query syntax.
    - `SYNTAX_QUERY`: Mroonga will use Groonga's query syntax, compatible with MariaDB's BOOLEAN MODE syntax. Unless `SYNTAX_SCRIPT` is specified, this mode is always in use.
    - `SYNTAX_SCRIPT`: Mroonga will use Groonga's script syntax, a JavaScript-like syntax. If both `SYNTAX_QUERY` and `SYNTAX_SCRIPT` are specified, `SYNTAX_SCRIPT` will take precedence..
- Command line: `--mroonga-boolean-mode-syntax-flags=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `DEFAULT`

`mroonga_database_path_prefix`

- Description: The database path prefix.
- Command line: `--mroonga-database-path-prefix=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)

`mroonga_default_parser`

- Description: The fulltext default parser, for example `TokenBigramSplitSymbolAlphaDigit` or `TokenBigram` (the default). See the list of options at Mroonga Overview:Parser. Deprecated since Mroonga 5.04, use mroonga_default_tokenizer instead.
- Command line: `--mroonga-default-parser=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `TokenBigram`
- Deprecated: MariaDB 10.1.6, Mroonga 5.0.4

`mroonga_default_tokenizer`

- Description: The fulltext default parser, for example `TokenBigramSplitSymbolAlphaDigit` or `TokenBigram` (the default). See the list of options at Mroonga Overview:Parser.
- Command line: `--mroonga-default-tokenizer=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `TokenBigram`
- Introduced: MariaDB 10.1.6, Mroonga 5.0.4

`mroonga_default_wrapper_engine`

- Description: The default engine for wrapper mode.

- Command line: `--mroonga-default-wrapper-engine=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)

`mroonga_dry_write`

- Description: If set to `on`, (`off` is default), data is not actually written to the Groonga database. Only really useful to change for benchmarking.
- Command line: `--mroonga-dry-write[={0|1}]`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `off`

`mroonga_enable_operations_recording`

- Description: Whether recording operations for recovery to the Groonga database is enabled (default) or not. Requires reopening the database with FLUSH TABLES after changing the variable.
- Command line: `--mroonga-enable-operations-recording={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.2.11, MariaDB 10.1.29

`mroonga_enable_optimization`

- Description: If set to `on` (the default), optimization is enabled. Only really useful to change for benchmarking.
- Command line: `--mroonga-enable-optimization={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `on`

`mroonga_libgroonga_embedded`

- Description: Whether libgroonga is embedded or not.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.1.6

`mroonga_libgroonga_support_lz4`

- Description: Whether libgroonga supports lz4 or not.
- Command line: None

- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`mroonga_libgroonga_support_zlib`

- Description: Whether libgroonga supports zlib or not.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`mroonga_libgroonga_support_zstd`

- Description: Whether libgroonga supports Zstandard or not.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.2.11, MariaDB 10.1.29

`mroonga_libgroonga_version`

- Description: Groonga library version.
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `string`

`mroonga_lock_timeout`

- Description: Lock timeout used in Groonga.
- Command line: `--mroonga-lock-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `900000`
- Range: `-1` to `2147483647`

`mroonga_log_file`

- Description: Name and path of the Mroonga log file.
- Command line: `--mroonga-log-file=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `groonga.log`

`mroonga_log_level`

- Description: Mroonga log file output level, which determines what is logged. Valid levels include:
  - `NONE` No output.
  - `EMERG`: Only emergency error messages, such as database corruption.
  - `ALERT`: Alert messages, such as internal errors.
  - `CRIT`: Critical error messages, such as deadlocks.
  - `ERROR`: Errors, such as API errors.
  - `WARNING`: Warnings, such as invalid arguments.
  - `NOTICE`: Notices, such as a change in configuration or a status change.
  - `INFO`: Information messages, such as file system operations.
  - `DEBUG`: Debug messages, suggested for developers or testers.
  - `DUMP`: Dump messages.
- Command line: `--mroonga-log-level=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `NOTICE`

`mroonga_match_escalation_threshold`

- Description: The threshold to determine whether the match method is escalated. `-1` means never escalate.
- Command line: `--mroonga-match-escalation-threshold=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-1` to `9223372036854775807`

`mroonga_max_n_records_for_estimate`

- Description: The max number of records to estimate the number of matched records
- Command line: `--mroonga-max-n-records-for-estimate=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1000`
- Range: `-1` to `2147483647`

`mroonga_query_log_file`

- Description: Query log file for Mroonga.
- Command line: `--mroonga-query-log-file=filename`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty string)
- Introduced: MariaDB 10.2.11

`mroonga_vector_column_delimiter`

- Description: Delimiter to use when outputting a vector column. The default is a white space.
- Command line: `--mroonga-vector-column-delimiter=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: `` (white space)

`mroonga_version`

- Description: Mroonga version
- Command line: None
- Scope: Global
- Dynamic: No
- Data Type: `string`

This page is licensed: CC BY-SA / Gnu FDL

Mroonga User-Defined Functions

See Creating Mroonga User-Defined Functions.

Instructions on how to manually create Mroonga's UDFs if they were not automatically installed, ensuring full functionality.

See last_insert_grn_id.

This UDF returns the unique ID assigned by Groonga for the last inserted record, useful for tracking internal record identifiers.

See mroonga_command.

Execute raw Groonga commands directly from MariaDB using this UDF, allowing for advanced administration and inspection of the Groonga database.

See mroonga_escape.

This function escapes special characters in a string to make it safe for use in Mroonga full-text search queries.

See mroonga_highlight_html.

Highlight keywords within a text string using HTML tags, making it easy to display search results with matched terms emphasized.

See mroonga_normalize.

This UDF normalizes a given string using Groonga's normalizers, ensuring consistent text processing for accurate indexing and searching.

See mroonga_snippet.

This function extracts a snippet of text surrounding a keyword from a document, providing necessary context for search result displays.

See mroonga_snippet_html.

Similar to mroonga_snippet, this function generates HTML-formatted snippets, automatically wrapping matched keywords in tags for web display.

This page is licensed: CC BY-SA / Gnu FDL

Creating Mroonga User-Defined Functions

The Mroonga storage engine includes a number of user-defined functions that need to be created before they can be used. If these are not created already during Mroonga setup, you will need to do so yourself. The full list of available functions and the statements to create them are found in `share/mroonga/install.sql`, for example, as of Mroonga 7.07 running on Linux:

```
DROP FUNCTION IF EXISTS last_insert_grn_id;
CREATE FUNCTION last_insert_grn_id RETURNS INTEGER
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet;
CREATE FUNCTION mroonga_snippet RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_command;
CREATE FUNCTION mroonga_command RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_escape;
CREATE FUNCTION mroonga_escape RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_snippet_html;
CREATE FUNCTION mroonga_snippet_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_normalize;
CREATE FUNCTION mroonga_normalize RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_highlight_html;
CREATE FUNCTION mroonga_highlight_html RETURNS STRING
  SONAME 'ha_mroonga.so';

DROP FUNCTION IF EXISTS mroonga_query_expand;
CREATE FUNCTION mroonga_query_expand RETURNS STRING
  SONAME 'ha_mroonga.so';
```

This page is licensed: CC BY-SA / Gnu FDL

last_insert_grn_id

Syntax

```
last_insert_grn_id()
```

Description

`last_insert_grn_id` is a user-defined function (UDF) included with the Mroonga storage engine. It returns the unique Groonga id of the last-inserted record. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

Examples

```
SELECT last_insert_grn_id();
+----------------------+
| last_insert_grn_id() |
+----------------------+
|                    3 |
+----------------------+
```

See Also

- Creating Mroonga User-Defined Functions

This page is licensed: CC BY-SA / Gnu FDL

mroonga_command

Syntax

```
mroonga_command (command)
```

Description

`mroonga_command` is a user-defined function (UDF) included with the Mroonga storage engine. It passes a command to Groonga for execution. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

- `command` - string, required parameter specifying the command to pass that are executed by Groonga. See the Groonga reference for a list of commands.

Returns the result of the Groonga command.

Note As a administrative function that sends commands directly into Groonga, it completely bypassed MariaDB privilege control. Do not create this UDF on a multi-user system that relies on privilege separation of accounts.

Example

```
SELECT mroonga_command('status');
+-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------+
| mroonga_command('status')
|
+-----------------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------------+
|
{"alloc_count":593,"starttime":1512022368,"start_time":1512022368,"uptime":13510,"version":"7.0.7","n_que
ries":0,"cache_hit_rate":0.0,"command_version":1,"default_command_version":1,"max_command_version":3} |
```

See Also

- Creating Mroonga User-Defined Functions

This page is licensed: CC BY-SA / Gnu FDL

mroonga_escape

Syntax

```
mroonga_escape (string [,special_characters])
```

- `string` - required parameter specifying the text you want to escape
- `special_characters` - optional parameter specifying the characters to escape

Description

`mroonga_escape` is a user-defined function (UDF) included with the Mroonga storage engine, used for escaping a string. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

If no `special_characters` parameter is provided, by default `+-<>*()":` are escaped.

Returns the escaped string.

Example

```
SELECT mroonga_escape("+-<>~*()\"\:");
'\\+\\-\\<\\>\\~\\*\\(\\)\\"\\:
```

See Also

- Creating Mroonga User-Defined Functions

This page is licensed: CC BY-SA / Gnu FDL

mroonga_highlight_html

Syntax

```
mroonga_highlight_html(text[[, query AS query]])

mroonga_highlight_html(text[[, keyword1, ..., keywordN]])
```

Description

`mroonga_highlight_html` is a user-defined function (UDF) included with the Mroonga storage engine. It highlights the specified keywords in the target text. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

The optional parameter can either be one or more *keywords*, or a Groonga *query*.

The function highlights the specified keywords in the target text by surrounding each keyword with `<span class="keyword">...</span>`, and escaping special HTML characters such as `<` and `>`.

Returns highlighted HTML.

Examples

```
SELECT mroonga_highlight_html('<p>MariaDB includes the Mroonga storage engine</p>.')
  AS highlighted_html;
+-------------------------------------------------------------------+
| highlighted_html                                                  |
+-------------------------------------------------------------------+
| &lt;p&gt;MariaDB includes the Mroonga storage engine&lt;/p&gt;. |
+-------------------------------------------------------------------+
```

Highlighting the words `MariaDB` and `Mroonga` in a given text:

```
SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB', 'Mroonga')
  AS highlighted_html;
+-----------------------------------------------------------------------------------------------------------------
+
| highlighted_html
|
+-----------------------------------------------------------------------------------------------------------------
+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span> storage engine.
|
+-----------------------------------------------------------------------------------------------------------------
+
```

The same outcome, formulated as a Groonga query:

```
SELECT mroonga_highlight_html('MariaDB includes the Mroonga storage engine.', 'MariaDB OR Mroonga'
  AS query) AS highlighted_text;
+-----------------------------------------------------------------------------------------------------------------
+
| highlighted_text
|
+-----------------------------------------------------------------------------------------------------------------
+
| <span class="keyword">MariaDB</span> includes the <span class="keyword">Mroonga</span> storage engine.
|
+-----------------------------------------------------------------------------------------------------------------
+
```

See Also

- Creating Mroonga User-Defined Functions

This page is licensed: CC BY-SA / Gnu FDL

mroonga_normalize

Syntax

```
mroonga_normalize(string[, normalizer_name])
```

Description

`mroonga_normalize` is a user-defined function (UDF) included with the Mroonga storage engine. It uses Groonga's normalizer to normalize text. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

Given a string, returns the normalized text.

See the Groonga Normalizer Reference for details on the Groonga normalizers. The default if no normalizer is provided is `NormalizerAuto`.

Examples

```
SELECT mroonga_normalize("AB▫▫");
+------------------------------+

mroonga_snippet

Syntax

```
mroonga_snippet document,
                max_length,
                max_count,
                encoding,
                skip_leading_spaces,
                html_escape,
                snippet_prefix,
                snippet_suffix,
                word1, word1_prefix, word1_suffix
                ...
                [wordN wordN_prefix wordN_suffix]
```

Description

`mroonga_snippet` is a user-defined function (UDF) included with the Mroonga storage engine. It provides a keyword with surrounding text, or the keyword in context. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

The required parameters include:

- `document` - Column name or string value.
- `max_length` - Maximum length of the snippet, in bytes.
- `max_count` - Maximum snippet elements (N word).
- `encoding` - Encoding of the document, for example `cp932_japanese_ci`
- `skip_leading_spaces` - `1` to skip leading spaces, `0` to not skip.
- `html_escape` = `1` to enable HTML espape, `0` to disable.
- `prefix` - Snippet start text.
- `suffix` - Snippet end text.

The optional parameters include:

- `wordN` - A word.
- `wordN_prefix` - wordN start text.
- `wordN_suffix` - wordN end text

It can be used in both storage and wrapper mode.

Returns the snippet string.

Example

```
```

mroonga_snippet_html

Description

`mroonga_snippet_html` is a user-defined function (UDF) included with the Mroonga storage engine. It provides a keyword with surrounding text, or the keyword in context. It is still considered experimental. See Creating Mroonga User-Defined Functions for details on creating this UDF if required.

MyISAM

See MyISAM Overview.

A detailed overview of the MyISAM storage engine, including its file structure, features, and limitations compared to newer engines like Aria.

See MyISAM Index Storage Space.

This page explains how MyISAM stores and compresses indexes, detailing space usage for different key types and compression strategies.

See MyISAM Storage Formats.

Learn about the three storage formats supported by MyISAM: FIXED (static), DYNAMIC (variable length), and COMPRESSED (read-only).

See MyISAM System Variables.

A reference for system variables that configure MyISAM behavior, such as key cache sizes, recovery modes, and concurrent insert settings.

This page is licensed: CC BY-SA / Gnu FDL

MyISAM Overview

The MyISAM storage engine was the default storage engine from MySQL 3.23 until it was replaced as default by InnoDB in MariaDB and MySQL 5.5. Historically, MyISAM is a replacement for the older ISAM engine, removed in MySQL 4.1.

It's a light, non-transactional engine with great performance, is easy to copy between systems and has a small data footprint.

You're encouraged to rather use the Aria storage engine for new applications, which has even better performance in most cases and the goal of being crash-safe.

A MyISAM table is stored in three files on disk. There's a table definition file with an extension of `.frm`, a data file with the extension `.MYD`, and an index file with the extension `.MYI`.

MyISAM features

- Does not support transactions.
- Does not support foreign keys.
- Supports FULLTEXT indexes.
- Supports GIS data types.

- Storage limit of 256TB.
- Maximum of 64 indexes per table.
- Maximum of 32 columns per index.
- Maximum index length of 1000 bytes.
- Limit of (232)2 (1.844E+19) rows per table.
- Supports large files up to 63-bits in length where the underlying system supports this.
- All data is stored with the low byte first, so all files will still work if copied to other systems or other machines.
- The data file and the index file can be placed on different devices to improve speed.
- Supports table locking, not row locking.
- Supports a key buffer that is segmented in MariaDB.
- Supports concurrent inserts.
- Supports fixed length, dynamic and compressed formats - see MyISAM Storage Formats.
- Numeric index values are stored with the high byte first, which enables more efficient index compression.
- Data values are stored with the low byte first, making it mostly machine and operating system independent. The only exceptions are if a machine doesn't use two's-complement signed integers and the IEEE floating-point format.
- Can be copied between databases or systems with normal system tools, as long as the files are not open on either system. Use FLUSH_TABLES to ensure files are not in use.
- There are a number of tools for working with MyISAM tables. These include:
  - mariadb-check for checking or repairing
  - myisamchk for checking or repairing
  - myisampack for compressing
- It is possible to build a MERGE table on the top of one or more MyISAM tables.

This page is licensed: CC BY-SA / Gnu FDL

MyISAM Index Storage Space

Regular MyISAM tables make use of B-tree indexes.

String indexes are space-compressed, which reduces the size of VARCHARs that don't use the full length, or a string that has trailing spaces. String indexes also make use of prefix-compression, where strings with identical prefixes are compressed.

Numeric indexes can also be prefix-compressed if the PACK_KEYS=1 option is used. Regardless, the high byte is always stored first, which allows a reduced index size.

In the worst case, with no strings being space-compressed, the total index storage space are (index_length+4)/0.67 per index.

This page is licensed: CC BY-SA / Gnu FDL

MyISAM Storage Formats

The MyISAM storage engine supports three different table storage formats.

These are FIXED, DYNAMIC and COMPRESSED. FIXED and DYNAMIC can be set with the ROW FORMAT option in the CREATE TABLE statement, or are chosen automatically depending on the columns the table contains. COMPRESSED can only be set via the myisampack tool.

The SHOW TABLE STATUS statement can be used to see the storage format used by a table. Note that `COMPRESSED` tables are reported as `DYNAMIC` in that context.

Fixed-length

Fixed-length (or static) tables contain records of a fixed-length. Each column is the same length for all records, regardless of the actual contents. It is the default format if a table has no BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a fixed table with ROW_FORMAT=FIXED in the table definition.

Tables containing BLOB or TEXT fields cannot be FIXED, as by design these are both dynamic fields. However, no error or warning are raised if you specify FIXED.

Fixed-length tables have a number of characteristics

- fast, since MariaDB will always know where a record begins
- easy to repair: myisamchk is always able to recover all rows, except for the last one if it is not entirely written
- easy to cache
- take up more space than dynamic or compressed tables, as the maximum amount of storage space are allocated to each record.
- reconstructing after a crash is uncomplicated due to the fixed positions
- no fragmentation or need to re-organize, unless records have been deleted and you want to free the space up.

Dynamic

Dynamic tables contain records of a variable length. It is the default format if a table has any BLOB, TEXT, VARCHAR or VARBINARY fields, and no ROW FORMAT is provided. You can also specify a DYNAMIC table with ROW_FORMAT=DYNAMIC in the table definition. If the table contains BLOB or TEXT columns, its format is always DYNAMIC, and the ROW FORMAT option is ignored.

Dynamic tables have a number of characteristics

- Each row contains a header indicating the length of the row.
- Rows tend to become fragmented easily. UPDATING a record to be longer will likely ensure it is stored in different places on the disk. Use OPTIMIZE TABLE when the fragmentation is too high.
- All string columns with a length of four or more are dynamic.
- They require much less space than fixed-length tables.
- Restoring after a crash is more complicated than with FIXED tables. Some fragments may be lost.

If a DYNAMIC table has some frequently-accessed fixed-length columns, it could be a good idea to move them into a separate FIXED table to avoid fragmentation.

Compressed

Compressed tables are a read-only format, created with the myisampack tool. This can be done while the server is running, but external lock must not be disabled. myisamchk is used to uncompress them.

Compressed tables have a number of characteristics:

- while the data is read-only, DDL statements such as DROP TABLE and TRUNCATE TABLE will still function.
- take much less space than fixed or dynamic tables. Each data has usually a 40-70% compression ratio
- rows are compressed separately, reducing access overhead.
- row headers are from one to three bytes.
- rows can be compressed with different compression types, including
  - prefix space compression
  - suffix space compression
  - columns with small sets of values are converted to ENUM
  - numeric zeros are stored with only one bit

- integer columns are reduced to the smallest int type that can hold the contents

See Also

- Why we still need MyISAM (for read-only tables) describes an important use case for MyISAM compressed tables.

MyISAM System Variables

This page documents system variables related to the MyISAM storage engine. For options, see MyISAM Options.

See Server System Variables for a complete list of system variables and instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

`key_buffer_size`

- Description: Size of the buffer for the index blocks used by MyISAM tables and shared for all threads. See Optimizing key_buffer_size for more on selecting the best value.
- Command line: `--key-buffer-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `134217728`
- Range: `8` upwards (upper limit determined by operating system per process limit)

`key_cache_age_threshold`

- Description: The lower the setting, the more quickly buffers move from the hot key cache sublist to the warm sublist.
- Command line: `--key-cache-age-threshold=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `300`
- Range: `100` to `4294967295`

`key_cache_block_size`

- Description: MyISAM key cache block size in bytes .
- Command line: `--key-cache-block-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1024`
- Range: `512` to `16384`

`key_cache_division_limit`

- Description: Percentage to use for the warm key cache buffer list (the remainder is allocated between the hot and cold caches).
- Command line: `--key-cache-division-limit=#`

- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `1` to `100`

`key_cache_file_hash_size`

- Description: Number of hash buckets for open and changed files. If you have many MyISAM files open you should increase this for faster flushing of changes. A good value is probably 1/10th of the number of possible open MyISAM files.
- Command line: `--key-cache-file-hash-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `512`
- Range: `128` to `16384`

`key_cache_segments`

- Description: The number of segments in a key cache. See Segmented Key Cache.
- Command line: `--key-cache-segments=#`
- Scope: Global
- Dynamic: Yes
- Type: numeric
- Default Value: `0` (non-segmented)
- Range: `0` to `64`

`myisam_block_size`

- Description: Block size to be used for MyISAM index pages.
- Command line: `--myisam-block-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1024`

`myisam_data_pointer_size`

- Description: Size in bytes of the default pointer, used in a MyISAM CREATE TABLE with no MAX_ROWS option.
- Command line: `--myisam-data-pointer-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `6`
- Range: `2` to `7`

`myisam_max_extra_sort_file_size`

- Description: Removed in MySQL 5.0.6, was used as a way to force long character keys in large tables to use the key cache method.
- Removed: MySQL 5.0.6

`myisam_max_sort_file_size`

- Description: Maximum size in bytes of the temporary file used while recreating a MyISAM index. If the this size is exceeded, the slower process of using the key cache is done instead.
- Command line: `--myisam-max-sort-file-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value - 32 bit: `2147483648`
- Default Value - 64 bit: `9223372036854775807`

`myisam_mmap_size`

- Description: Maximum memory in bytes that can be used for memory mapping compressed MyISAM files. Too high a value may result in swapping if there are many compressed MyISAM tables.
- Command line: `--myisam-mmap-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value - 32 bit: `4294967295`
- Default Value - 64 bit: `18446744073709547520`
- Range - 32-bit: `7` to `4294967295`
- Range - 64-bit: `7` to `18446744073709547520`

`myisam_recover_options`

- Description: MyISAM recovery mode. Multiple options can be selected, comma-delimited. Using no argument is equivalent to specifying `DEFAULT`, while specifying “” is equivalent to `OFF`. If enabled each time the server opens a MyISAM table, it checks whether it has been marked as crashed, or wasn’t closed properly. If so, mysqld will run a check and then attempt to repair the table, writing to the error log beforehand.
  - OFF: No recovery.
  - BACKUP: If the data file is changed while recovering, saves a backup of the .MYD data file. t.MYD are saved as t.MYD-datetime.BAK.
  - BACKUP_ALL: Same as `BACKUP` but also backs up the .MYI index file. t.MYI are saved as t.MYI-datetime.BAK.
  - DEFAULT: Recovers without backing up, forcing, or quick checking.
  - FORCE: Runs the recovery even if it determines that more than one row from the data file are lost.
  - QUICK: Does not check rows in the table if there are no delete blocks.
- Command line: `--myisam-recover-options[=name]`
- Scope: Global
- Dynamic: No
- Data Type: `enumeration`
- Default Value:

    - `BACKUP,QUICK` (>= MariaDB 10.2.4)
    - `DEFAULT` (<= MariaDB 10.2.3)
    - `OFF`
- Valid Values: `OFF`, `DEFAULT`, `BACKUP`, `BACKUP_ALL`, `FORCE` or `QUICK`

`myisam_repair_threads`

- Description: If set to more than `1`, the default, MyISAM table indexes each have their own thread during repair and sorting. Increasing from the default will usually result in faster repair, but will use more CPU and memory.
- Command line: `--myisam-repair-threads=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range - 32-bit: `1` to `4294967295`
- Range - 64-bit: `1` to `18446744073709547520`

`myisam_sort_buffer_size`

- Description: Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table. Increase for better myisamchk -r, –recover performance.
- Command line: `--myisam-sort-buffer-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `BIGINT UNSIGNED`
- Default Value: `134216704`
- Range:
    - (>= MariaDB 10.11.5, MariaDB 10.6.15) : `4096` to `1152921504606846975`
    - (< = MariaDB 10.11.4, MariaDB 10.6.14) : `4096` to `18446744073709551615`

`myisam_stats_method`

- Description: Determines how NULLs are treated for the purposes of MyISAM index statistics. If set to `nulls_equal`, all NULL index values are treated as a single group. This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. If set to `nulls_unequal`, the default, the opposite approach is taken, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. Setting to `nulls_ignored` ignores NULLs altogether from index group calculations. See also Index Statistics, aria_stats_method, innodb_stats_method.
- Command line: `--myisam-stats-method=name`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `enumeration`
- Default Value: `NULLS_UNEQUAL`
- Valid Values: `NULLS_UNEQUAL, NULLS_EQUAL, NULLS_IGNORED`

`myisam_use_mmap`

- Description: If set to `1` (0 is default), memory mapping are used to reading and writing MyISAM tables.

- Command line: `--myisam-use-mmap`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

About MyRocks for MariaDB

About MyRocks for MariaDB

MyRocks is an open source storage engine that was originally developed by Facebook.

MyRocks has been extended by the MariaDB engineering team to be a pluggable storage engine that you use in your MariaDB solutions. It works seamlessly with MariaDB features. This openness in the storage layer allows you to use the right storage engine to optimize your usage requirements, which provides optimum performance. Community contributions are one of MariaDB's greatest advantages over other databases. Under the lead of our developer Sergey Petrunia, MyRocks in MariaDB is occasionally being merged with upstream MyRocks from Facebook.

Aria

MariaDB's pluggable storage layer: engines grouped by purpose, with MyRocks among the performance-and-scalability engines.

MyRocks, typically, gives greater performance for web scale type applications. It can be an ideal storage engine solution when you have workloads that require greater compression and IO efficiency. It uses a Log Structured Merge (LSM) architecture, which has advantages over B-Tree algorithms, to provide efficient data ingestion, like read-free replication slaves, or fast bulk data loading.
MyRocks distinguishing features include:

- compaction filter
- merge operator
- backup
- column families
- bulk loading
- persistent cache

For more MyRocks features see: Features-Not-in-LevelDB

Benefits

On production workloads, MyRocks was tested to prove that it provides:

Greater Space Efficiency

- 2x more compression
  MyRocks has 2x better compression compared to compressed InnoDB, 3-4x better compression compared to uncompressed InnoDB, meaning you use less space.

Greater Writing Efficiency

- 2x lower write rates to storage
  MyRocks has a 10x less write amplification compared to InnoDB, giving you better endurance of flash storage and improving overall throughput.

Faster Data Loading

- faster database loads
  MyRocks writes data directly onto the bottommost level, which avoids all compaction overheads when you enable faster data loading for a session.

Faster Replication

- No random reads for updating secondary keys, except for unique indexes. The Read-Free Replication option does away with random reads when updating primary keys, regardless of uniqueness, with a row-based binary logging format.

myrocks.iofacebook-myrocks-mariadb

Requirements and Limitations

- MyRocks is included from MariaDB 10.2.5.
- MyRocks is available in the MariaDB Server packages for Linux and Windows.
- Maria DB optimistic parallel replication may not be supported.
- MyRocks is not available for 32-bit platforms
- Galera Cluster is tightly integrated into InnoDB storage engine (it also supports Percona's XtraDB which is a modified version of InnoDB). Galera Cluster does not work with any other storage engines, including MyRocks.

MyRocks builds are available on platforms that support a sufficiently modern compiler, for example:

- Ubuntu Trusty, Xenial, (amd64 and ppc64el)
- Ubuntu Yakkety (amd64)
- Debian Jessie, stable (amd64, ppc64el)
- Debian Stretch, Sid (testing and unstable) (amd64)
- CentOS/RHEL 7 (amd64)
- Centos/RHEL 7.3 (amd64)
- Fedora 24 and 25 (amd64)
- OpenSUSE 42 (amd64)
- Windows 64 (zip and MSI)

This page is licensed: CC BY-SA / Gnu FDL

Building MyRocks in MariaDB

This page describes how to get MyRocks in MariaDB when compiling MariaDB from source. (See Build-Steps for instructions how to build the upstream.)

Build Process and Requirements

MariaDB compile process will compile MyRocks into `ha_rocksdb.so` by default if the platform supports it (That is, no WITH_ROCKSDB switch is necessary).

Platform requirements:

- A 64-bit platform (due to some 32 bit compilers having difficulties with RocksDB)
- git installed (or git submodules fetched somehow)
- A sufficiently recent compiler:
  - gcc >= 4.8, or
  - clang >= 3.3, or
  - MS Visual Studio 2015 or newer

Building on Ubuntu 16.04

The steps were checked on a fresh install of Ubuntu 16.04.2 LTS Xenial.

```
sudo apt-get update
sudo apt-get -y install g++ cmake libbz2-dev libaio-dev bison zlib1g-dev libsnappy-dev
sudo apt-get -y install libgflags-dev libreadline6-dev libncurses5-dev libssl-dev liblz4-dev gdb git
;
```

```
git clone https://github.com/MariaDB/server.git mariadb-10.2
cd mariadb-10.2
git checkout 10.2
git submodule init
git submodule update
cmake .
make -j10
```

This should produce `storage/rocksdb/ha_rocksdb.so` which is MyRocks storage engine in the loadable form.

Starting MyRocks

MyRocks does not require any special way to initialize the data directory.
Minimal my.cnf flle:

```
cat > ~/my1.cnf <<EOF
[mysqld]

datadir=../mysql-test/var/install.db
plugin-dir=../storage/rocksdb
language=./share/english
socket=/tmp/mysql.sock
port=3307

plugin-load=ha_rocksdb
default-storage-engine=rocksdb
EOF
```

Run the server like this

```
(cd mysql-test; ./mtr alias)
cp -r mysql-test/var/install.db ~/data1
cd ../sql
./mysqld --defaults-file=~/my1.cnf
```

Compression libraries.
Supported compression libraries are listed in rocksdb_supported_compression_types. Compiling like the above, I get:

```
Snappy,Zlib,LZ4,LZ4HC
```

This page is licensed: CC BY-SA / Gnu FDL

Differences Between MyRocks Variants

MyRocks is available in

- Facebook's (FB) MySQL branch (originally based on MySQL 5.6)
- MariaDB (from 10.2 and 10.3)
- Percona Server from 5.7

This page lists differences between these variants.

This is a work in progress. The contents are not final

RocksDB Data Location

FB and Percona store RocksdDB files in $datadir/`.rocksdb`. MariaDB puts them in $datadir/`#rocksdb`. This is more friendly for packaging and OS scripts.

Compression Algorithms

- FB's branch doesn't provide binaries. One needs to compile it with appropriate compression libraries.
- In MariaDB, available compression algorithms can be seen in the rocksdb_supported_compression_types variable. From MariaDB 10.7, algorithms can be installed as a plugin. In earlier versions, the set of supported compression algorithms depends on the platform.
  - On Ubuntu 16.04 (current LTS) it is `Snappy,Zlib,LZ4,LZ4HC` .
  - On CentOS 7.4 it is `Snappy,Zlib`.
  - In the bintar tarball it is `Snappy,Zlib`.
- Percona Server supports: `Zlib, ZSTD, LZ4 (the default), LZ4HC`. Unsupported algorithms: `Snappy, BZip2, XPress`.

RocksDB Version Information

- FB's branch provides the `rocksdb_git_hash` *status* variable.
- MariaDB provides the `@@rocksdb_git_hash` *system* variable.
- Percona Server doesn't provide either.

RocksDB Version

- Facebook's branch uses RocksDB 5.10.0 (the version number can be found in `include/rocksdb/version.h`)

```
commit ba295cda29daee3ffe58549542804efdfd969784
Author: Andrew Kryczka <andrewkr@fb.com>
Date:   Fri Jan 12 11:03:55 2018 -0800
```

- MariaDB currently uses 5.8.0

```
commit 9a970c81af9807071bd690f4c808c5045866291a
Author: Yi Wu <yiwu@fb.com>
Date:   Wed Sep 13 17:21:35 2017 -0700
```

- Percona Server uses 5.8.0

```
commit ab0542f5ec6e7c7e405267eaa2e2a603a77d570b
Author: Maysam Yabandeh <myabandeh@fb.com>
Date:   Fri Sep 29 07:55:22 2017 -0700
```

Binlog Position in information_schema.rocksdb_global_info

- FB branch provides information_schema.rocksdb_global_info type=BINLOG, NAME={FILE, POS, GTID}.
- Percona Server doesn't provide it.
- MariaDB doesn't provide it.

One use of that information is to take the output of `myrocks_hotbackup` and make it a new master.

Gap Lock Detector

- FB branch has a "Gap Lock Detector" feature. It is at the SQL layer. It can be controlled with `gap_lock_XXX` variables and is disabled by default (gap-lock-raise-error=false, gap-lock-write-lock=false).
- Percona Server has gap lock checking ON but doesn't seem to have any way to control it?
  Queries that use Gap Lock on MyRocks fail with an error like this:

```
INSERT INTO tbl2 SELECT * FROM tbl1;
ERROR 1105 (HY000): Using Gap Lock without full unique key in multi-table or multi-statement transactions
is not allowed. You need to either rewrite queries to use all unique key columns in WHERE equal
conditions,
or rewrite to single-table, single-statement transaction.  Query: insert into tbl2 select * from tbl1
```

- MariaDB doesn't include the Gap Lock Detector.

Generated Columns

- Both MariaDB and Percona Server support generated columns, but neither one supports them for the MyRocks storage engine (attempts to create a table will produce an error).
- Invisible columns in MariaDB 10.3 are supported (as they are an SQL layer feature).

rpl_skip_tx_api

Facebook's branch has a performance feature for replication slaves, `rpl_skip_tx_api`. It is not available in MariaDB or in Percona Server.

Details

The above comparison was made using

- FB/MySQL 5.6.35
- Percona Server 5.7.20-19-log
- MariaDB 10.2.13 (MyRocks is beta)

This page is licensed: CC BY-SA / Gnu FDL

Getting Started with MyRocks

MyRocks is a storage engine that adds the RocksDB database to MariaDB. RocksDB is an LSM database with a great compression ratio that is optimized for flash storage.

The storage engine must be installed before it can be used.

Installing the Plugin's Package

The MyRocks storage engine's shared library is included in MariaDB packages as the `ha_rocksdb.so` or `ha_rocksdb.dll` shared library on systems where it can be built.

Installing on Linux

The MyRocks storage engine is included in binary tarballs on Linux.

Installing with a Package Manager

The MyRocks storage engine can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using yum or dnf. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`:

```
sudo yum install MariaDB-rocksdb-engine
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using apt-get:

```
sudo apt-get install mariadb-plugin-rocksdb
```

Installing with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using zypper:

```
sudo zypper install MariaDB-rocksdb-engine
```

Installing on Windows

The MyRocks storage engine is included in MSI and ZIP packages on Windows.

Installing the Plugin

Once the shared library is in place, the plugin is not actually installed by MariaDB by default. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN:

```
INSTALL SONAME 'ha_rocksdb';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the –plugin-load or the –plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file:

```
[mariadb]
...
plugin_load_add = ha_rocksdb
```

Note: When installed with a package manager, an option file that contains the –plugin-load-add option may also be installed. The RPM package installs it as `/etc/my.cnf.d/rocksdb.cnf`, and the DEB package installs it as `/etc/mysql/mariadb.conf.d/rocksdb.cnf`

Uninstalling the Plugin

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN:

```
UNINSTALL SONAME 'ha_rocksdb';
```

If you installed the plugin by providing the –plugin-load or the –plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Verifying the Installation

After installing MyRocks you will see RocksDB in the list of plugins:

```
SHOW PLUGINS;
+-------------------------------+----------+--------------------+---------------+---------+
| Name                          | Status   | Type               | Library       | License |
+-------------------------------+----------+--------------------+---------------+---------+
...
| ROCKSDB                       | ACTIVE   | STORAGE ENGINE     | ha_rocksdb.so | GPL     |
| ROCKSDB_CFSTATS               | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_DBSTATS               | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_PERF_CONTEXT          | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_PERF_CONTEXT_GLOBAL   | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_CF_OPTIONS            | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_COMPACTION_STATS      | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_GLOBAL_INFO           | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_DDL                   | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_INDEX_FILE_MAP        | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_LOCKS                 | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
| ROCKSDB_TRX                   | ACTIVE   | INFORMATION SCHEMA | ha_rocksdb.so | GPL     |
...
+-------------------------------+----------+--------------------+---------------+---------+
```

Compression

Supported compression types are listed in the rocksdb_supported_compression_types variable:

```
SHOW VARIABLES LIKE 'rocksdb_supported_compression_types';
+-----------------------------------+-------------+
| Variable_name                     | Value       |
+-----------------------------------+-------------+
| rocksdb_supported_compression_types | Snappy,Zlib |
+-----------------------------------+-------------+
```

See MyRocks and Data Compression for more.

System and Status Variables

All MyRocks system variables and status variables are prefaced with “rocksdb”, so you can query them with, for example:

```
SHOW VARIABLES LIKE 'rocksdb%';
SHOW STATUS LIKE 'rocksdb%';
```

This page is licensed: CC BY-SA / Gnu FDL

Loading Data Into MyRocks

Being a write-optimized storage engine, MyRocks has special ways to load data much faster than normal INSERTs would.

See:

- the section about “Migrating from InnoDB to MyRocks in production” has some clues.
- Data-Loading covers the topic in greater detail.

> **Note:**
>
> When loading data with rocksdb_bulk_load=1 and the data conflicts with the data already in the database, one may get non-trivial errors, for example:

```
ERROR 1105 (HY000): [./.rocksdb/test.t1_PRIMARY_2_0.bulk_load.tmp] bulk load error:
  Invalid argument: External file requires flush
```

This page is licensed: CC BY-SA / Gnu FDL

MyRocks Bloom Filters

Bloom filters are used to reduce read amplification. Bloom filters can be set on a per-column family basis (see myrocks-column-families).

Bloom Filter Parameters

- How many bits to use
- whole_key_filtering=true/false
- Whether the bloom filter is for the entire key or for the prefix. In case of a prefix, you need to look at the index definition and compute the desired prefix length.

Computing Prefix Length

- It’s 4 bytes for `index_nr`

- Then, for fixed-size columns (integer, date[time], decimal) it is key_length as shown by `EXPLAIN`. For VARCHAR columns, determining the length is tricky (It depends on the values stored in the table. Note that MyRocks encodes VARCHARs with "Variable-Length Space-Padded Encoding" format).

Configuring Bloom Filter

To enable 10-bit bloom filter for 8-byte prefix length for column family "cf1", put this into my.cnf:

```
rocksdb_override_cf_options='cf1={block_based_table_factory=
{filter_policy=bloomfilter:10:false;whole_key_filtering=0;};prefix_extractor=capped:8};'
```

and restart the server.

Check if the column family actually uses the bloom filter:

```
SELECT *
FROM information_schema.rocksdb_cf_options
WHERE
  cf_name='cf1' AND
  option_type IN ('TABLE_FACTORY::FILTER_POLICY','PREFIX_EXTRACTOR');
```

```
+---------+-------------------------------+---------------------------+
| CF_NAME | OPTION_TYPE                   | VALUE                     |
+---------+-------------------------------+---------------------------+
| cf1     | PREFIX_EXTRACTOR              | rocksdb.CappedPrefix.8    |
| cf1     | TABLE_FACTORY::FILTER_POLICY | rocksdb.BuiltinBloomFilter |
+---------+-------------------------------+---------------------------+
```

Checking if Bloom Filter is Useful

Watch these status variables:

```
SHOW status LIKE '%bloom%';
+-----------------------------------+-------+
| Variable_name                     | Value |
+-----------------------------------+-------+
| Rocksdb_bloom_filter_prefix_checked | 1     |
| Rocksdb_bloom_filter_prefix_useful  | 0     |
| Rocksdb_bloom_filter_useful         | 0     |
+-----------------------------------+-------+
```

Other useful variables are:

- `rocksdb_force_flush_memtable_now` - bloom filter is only used when reading data from disk. If you are doing testing, flush the data to disk first.
- `rocksdb_skip_bloom_filter_on_read` - skip using the bloom filter (default is FALSE).

This page is licensed: CC BY-SA / Gnu FDL

MyRocks CHECK TABLE

MyRocks supports the CHECK TABLE command.

The command will do a number of checks to verify that the table data is self-consistent.

The details about the errors are printed into the error log.
If log_warnings > 2, the error log will also have some informational messages which can help with troubleshooting.

Besides this, RocksDB has its own (low-level) log in `#rocksdb/LOG` file.

This page is licensed: CC BY-SA / Gnu FDL

MyRocks Data Compression

MyRocks supports several compression algorithms.

Supported Compression Algorithms

Supported compression algorithms can be checked like so:

```
SHOW variables LIKE 'rocksdb%compress%';
+-----------------------------------+----------------------------------+
| Variable_name                     | Value                            |
+-----------------------------------+----------------------------------+
| rocksdb_supported_compression_types | Snappy,Zlib,LZ4,LZ4HC,ZSTDNotFinal |
+-----------------------------------+----------------------------------+
```

Another way to make the check is to look into `#rocksdb/LOG` file in the data directory. It should have lines like:

```
2019/04/12-14:08:23.869919 7f839188b540 Compression algorithms supported:
2019/04/12-14:08:23.869920 7f839188b540         kZSTDNotFinalCompression supported: 1
2019/04/12-14:08:23.869922 7f839188b540         kZSTD supported: 1
2019/04/12-14:08:23.869923 7f839188b540         kXpressCompression supported: 0
2019/04/12-14:08:23.869924 7f839188b540         kLZ4HCCompression supported: 1
2019/04/12-14:08:23.869924 7f839188b540         kLZ4Compression supported: 1
2019/04/12-14:08:23.869925 7f839188b540         kBZip2Compression supported: 0
2019/04/12-14:08:23.869926 7f839188b540         kZlibCompression supported: 1
2019/04/12-14:08:23.869927 7f839188b540         kSnappyCompression supported: 1
```

Compression Settings

Compression is set on a per-Column Family basis. See MyRocks Column Families.

Checking Compression Settings

To check current compression settings for a column family one can use a query like so:

```
SELECT * FROM information_schema.rocksdb_cf_options
WHERE option_type LIKE '%ompression%' AND cf_name='DEFAULT';
```

The output are like:

```
+---------+---------------------------------------+---------------------------+
| CF_NAME | OPTION_TYPE                           | VALUE                     |
+---------+---------------------------------------+---------------------------+
| default | COMPRESSION_TYPE                      | kSnappyCompression        |
| default | COMPRESSION_PER_LEVEL                 | NUL                       |
| default | COMPRESSION_OPTS                      | -14:32767:0               |
| default | BOTTOMMOST_COMPRESSION                | kDisableCompressionOption |
| default | TABLE_FACTORY::VERIFY_COMPRESSION     | 0                         |
| default | TABLE_FACTORY::ENABLE_INDEX_COMPRESSION | 1                       |
+---------+---------------------------------------+---------------------------+
```

Current column family settings are used for the new SST files.

Modifying Compression Settings

Compression settings are not dynamic parameters, one cannot change them by setting rocksdb_update_cf_options.

The procedure to change compression settings is as follows:

- Edit `my.cnf` to set rocksdb_override_cf_options.

Example:

```
rocksdb-override-cf-options='cf1={compression=kZSTD;bottommost_compression=kZSTD;}'
```

- Restart the server.

The data will not be re-compressed immediately. However, all new SST files will use the new compression settings, so as data gets inserted/updated the column family will gradually start using the new option.

Caveat: Syntax Errors

Please note that `rocksdb-override-cf-options` syntax is quite strict. Any typos will result in the parse error, and MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded:

```
SELECT * FROM information_schema.plugins WHERE plugin_name='ROCKSDB'
```

(note that you need the “ROCKSDB” plugin. Other auxiliary plugins like “ROCKSDB_TRX” might still get loaded).

Another way is to detect the error is check the error log. When option parsing fails, it will contain messages like so:

```
2019-04-16 11:07:57 140283675678016 [Warning] Invalid cf config for cf1 in override options (options:
cf1={compression=kLZ4Compression;bottommost_compression=kZSTDCompression;})
2019-04-16 11:07:57 140283675678016 [ERROR] RocksDB: Failed to initialize CF options map.
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' init function returned error.
2019-04-16 11:07:57 140283675678016 [ERROR] Plugin 'ROCKSDB' registration as a STORAGE ENGINE failed.
```

Checking How the Data is Compressed

A query to check what compression is used in the SST files that store the data for a given table (test.t1):

```
SELECT
  SP.sst_name, SP.compression_algo
FROM
  information_schema.rocksdb_sst_props SP,
  information_schema.rocksdb_ddl D,
  information_schema.rocksdb_index_file_map IFM
WHERE
  D.table_schema='test' AND D.table_name='t1' AND
  D.index_number= IFM.index_number AND
  IFM.sst_name=SP.sst_name;
```

Example output:

```
+------------+------------------+
| sst_name   | compression_algo |
+------------+------------------+
| 000028.sst | Snappy           |
| 000028.sst | Snappy           |
| 000026.sst | Snappy           |
| 000026.sst | Snappy           |
+------------+------------------+
```

This page is licensed: CC BY-SA / Gnu FDL

MyRocks Group Commit with Binary log

MyRocks supports group commit with the binary log (MDEV-11934).

Counter Values to Watch

(The following is only necessary if you are studying MyRocks internals)

MariaDB's group commit counters are:

Binlog_commits - how many transactions were written to the binary log

Binlog_group_commits - how many group commits happened. (e.g. if each group had two transactions, this is twice as small as Binlog_commits)

On the RocksDB side, there is one relevant counter:Rocksdb_wal_synced - How many times RocksDB's WAL file was synced. (TODO: this is after group commit happened, right?)

On the Value of rocksdb_wal_group_syncs

FB/MySQL-5.6 has a rocksdb_wal_group_syncs counter (The counter is provided by MyRocks, it is not a view of a RocksDB counter). It is increased in rocksdb_flush_wal() when doing the rdb->FlushWAL() call.

rocksdb_flush_wal() is called by MySQL's Group Commit when it wants to make the effect of several rocksdb_prepare() calls persistent.

So, the value of rocksdb_wal_group_syncs in FB/MySQL-5.6 is similar to Binlog_group_commits in MariaDB.

MariaDB doesn't have that call, each rocksdb_prepare() call takes care of being persistent on its own.

Because of that, rocksdb_wal_group_syncs is zero for MariaDB. (Currently, it is only incremented when the binlog is rotated).

Examples

So for a workload with concurrency=50, n_queries=10K, one gets

- Binlog_commits=10K
- Binlog_group_commits=794
- Rocksdb_wal_synced=8362

This is on a RAM disk

For a workload with concurrency=50, n_queries=10K, rotating laptop hdd, one gets

- Binlog_commits= 10K
- Binlog_group_commits=1403
- Rocksdb_wal_synced=400

The test took 38 seconds, Number of syncs was 1400+400=1800, which gives 45 syncs/sec which looks normal for this slow rotating desktop hdd.

Note that the WAL was synced fewer times than there were binlog commit groups (?)

MyRocks Index-Only Scans

This article is about MyRocks and index-only scans on secondary indexes. It applies to MariaDB's MyRocks, Facebook's MyRocks, and other variants.

Secondary Keys Only

The primary key in MyRocks is always the clustered key, that is, the index record is THE table record and so it's not possible to do "index only" because there isn't anything that is not in the primary key's (Key,Value) pair.

Secondary keys may or may not support index-only scans, depending on the datatypes of the columns that the query is trying to read.

Background: Mem-Comparable Keys

MyRocks indexes store “mem-comparable keys” (that is, the key values are compared with `memcmp`). For some datatypes, it is easily possible to convert between the column value and its mem-comparable form, while for others the conversion is one-way.

For example, in case-insensitive collations capital and regular letters are considered identical, i.e. ‘c’ =‘C’. For some datatypes, MyRocks stores some extra data which allows it to restore the original value back. (For the `latin1_general_ci` collation and character ‘c’, for example, it will store one bit which says whether the original value was a small ‘c’ or a capital letter ‘C’). This doesn’t work for all datatypes, though.

Index-Only Support for Various Datatypes

Index-only scans are supported for numeric and date/time datatypes. For CHAR and VAR[CHAR], it depends on which collation is used, see below for details.

Index-only scans are currently not supported for less frequently used datatypes, like

- BIT(n)
- SET(…)
- ENUM(…)
  It is actually possible to add support for those, feel free to write a patch or at least make a case why a particular datatype is important

Index-Only Support for Various Collations

As far as Index-only support is concerned, MyRocks distinguishes three kinds of collations:

1. Binary (Reversible) Collations

These are `binary`, `latin1_bin`, and `utf8_bin`.

For these collations, it is possible to convert a value back from its mem-comparable form. Hence, one can restore the original value back from its index record, and index-only scans are supported.

2. Restorable Collations

These are collations where one can store some extra information which helps to restore the original value.

Criteria (from storage/rocksdb/rdb_datadic.cc, rdb_is_collation_supported()) are:

- The charset should use 1-byte characters (so, unicode-based collations are not included)
- strxfrm(1 byte) = {one 1-byte weight value always}
- no binary sorting
- PAD attribute

The examples are: `latin1_general_ci`, `latin1_general_cs`, `latin1_swedish_ci`, etc.

Index-only scans are supported for these collations.

3. All Other Collations

For these collations, there is no known way to restore the value from its mem-comparable form, and so index-only scans are not supported.

MyRocks needs to fetch the clustered PK record to get the field value.

Covering Secondary Key Lookups for VARCHARs

TODO: there is also this optimization:

303f349c95848e92b5b27b44f0e57194100eb0997e7

document it.

This page is licensed: CC BY-SA / Gnu FDL

MyRocks and Replication

Details about how MyRocks works with replication.

MyRocks and Statement-Based Replication

Statement-based replication (SBR) works as follows: SQL statements are executed on the master (possibly concurrently). They are written into the binlog (this fixes their ordering, “a serialization”). The slave then reads the binlog and executes the statements in their binlog order.

In order to prevent data drift, serial execution of statements on the slave must have the same effect as concurrent execution of these statements on the master. In other words, transaction isolation on the master must be close to `SERIALIZABLE` transaction isolation level (This is not a strict mathematical proof but shows the idea).

InnoDB achieves this by (almost) supporting `SERIALIZABLE` transactional isolation level. It does so by supporting “Gap Locks”. MyRocks doesn’t support `SERIALIZABLE` isolation, and it doesn’t support gap locks.

Because of that, generally one cannot use MyRocks and statement-based replication.

Updating a MyRocks table while having SBR on, will result in an error as follow:

```
ERROR 4056 (HY000): Can't execute updates on master with binlog_format != ROW.
```

Can One Still Use SBR with MyRocks?

Yes. In many cases, database applications run a restricted set of SQL statements, and it’s possible to prove that lack of Gap Lock support is not a problem and data skew will not occur.

In that case, one can set `@@rocksdb_unsafe_for_binlog=1` and MyRocks will work with SBR. The user is however responsible for making sure their queries are not causing a data skew.

Differences From Upstream MyRocks

MyRocks upstream (that is, Facebook’s MySQL branch) has a number of unique replication enhancements. These are available in upstream’s version of MyRocks but not in MariaDB’s version of MyRocks.

- Read-Free Replication (see Read-Free-Replication) TODO
- `<<unique_check_lag_threshold>>`. This is FB/MySQL-5.6 feature where unique checks are disabled if replication lag exceeds a certain threshold.
- `<<slave_gtid_info=OPTIMIZED>>`. This is said to be:

```
<<quote>>
"Whether SQL threads update mysql.slave_gtid_info table. If this value "
"is OPTIMIZED, updating the table is done inside storage engines to "
"avoid MySQL layer's performance overhead",
<</quote>>
```

This page is licensed: CC BY-SA / Gnu FDL

MyRocks START TRANSACTION WITH CONSISTENT SNAPSHOT

FB/MySQL has added new syntax:

```
START TRANSACTION WITH CONSISTENT ROCKSDB|INNODB SNAPSHOT;
```

The statement returns the binlog coordinates pointing at the snapshot.

MariaDB (and Percona Server) support extension to the regular

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

syntax as documented in Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.

After issuing the statement, one can examine the binlog_snapshot_file and binlog_snapshot_position status variables to see the binlog position that corresponds to the snapshot.

See Also

- START TRANSACTION
- Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT

This page is licensed: CC BY-SA / Gnu FDL

MyRocks Column Families

MyRocks stores data in column families. These are similar to tablespaces.
By default, the data is stored in the `default` column family.

One can specify which column family the data goes to by using index comments:

```
INDEX index_name(col1, col2, ...) COMMENT 'column_family_name'
```

If the column name starts with `rev:`, the column family is reverse-ordered.

Reasons for Column Families

Storage parameters like

- Bloom filter settings
- Compression settings
- Whether the data is stored in reverse order

are specified on a per-column family basis.

Creating a Column Family

When creating a table or index, you can specify the name of the column family for it. If the column family doesn't exist, it are automatically created.

Dropping a Column Family

There is currently no way to drop a column family.
RocksDB supports this internally but MyRocks doesn't provide any way to do it.

Setting Column Family Parameters

Use these variables:

- rocksdb_default_cf_options - a my.cnf parameter specifying default options for all column families.
- rocksdb_override_cf_options - a my.cnf parameter specifying per-column family option overrides.
- rocksdb_update_cf_options - a dynamically-settable variable which allows to change parameters online. Not all parameters can be changed.

rocksdb_override_cf_options

This parameter allows one to override column family options for specific column families.
Here is an example of how to set option1=value1 and option2=value for column family cf1, and option3=value3 for column family cf3:

```
rocksdb_override_cf_options='cf1={option1=value1;option2=value2};cf2={option3=value3}'
```

One can check the contents of `INFORMATION_SCHEMA.ROCKSDB_CF_OPTIONS` to see what options are available.

Options that are frequently configured are:

- Data compression. See myrocks-and-data-compression.
- Bloom Filters. See myrocks-and-bloom-filters.

Examining Column Family Parameters

See the INFORMATION_SCHEMA.ROCKSDB_CF_OPTIONS table.

This page is licensed: CC BY-SA / Gnu FDL

MyRocks Performance Troubleshooting

MyRocks exposes its performance metrics through several interfaces:

- Status variables
- `SHOW ENGINE ROCKSDB STATUS`
- RocksDB's perf context

the contents slightly overlap, but each source has its own unique information, so be sure to check all three.

Status Variables

Check the output of

```
SHOW STATUS LIKE 'Rocksdb%'
```

See MyRocks Status Variables for more information.

SHOW ENGINE ROCKSDB STATUS

This produces a lot of information.

One particularly interesting part is compaction statistics. It shows the amount of data on each SST level and other details:

```
*************************** 4. row ***************************
  Type: CF_COMPACTION
  Name: default
Status:
** Compaction Stats [default] **
Level    Files   Size     Score Read(GB)  Rn(GB) Rnp1(GB) Write(GB) Wnew(GB) Moved(GB) W-Amp Rd(MB/s)
Wr(MB/s) Comp(sec) Comp(cnt) Avg(sec) KeyIn KeyDrop
------------------------------------------------------------------------------------------------------------
------------------------------------------------
  L0      3/0   30.16 MB   1.0      0.0     0.0      0.0      11.9     11.9       0.0   1.0      0.0
76.6       159       632    0.251       0      0
  L1      5/0   247.54 MB   1.0      0.7     0.2      0.5       0.5      0.0      11.6   2.6     58.5

45.3        19         6    3.133     33M  3588K
```

Performance Context

RocksDB has an internal mechanism called “perf context”. The counter values are exposed through two tables:

- INFORMATION_SCHEMA.ROCKSDB_PERF_CONTEXT_GLOBAL - global counters
- INFORMATION_SCHEMA.ROCKSDB_PERF_CONTEXT - Per-table/partition counters

By default statistics are NOT collected. One needs to set rocksdb_perf_context_level to some value (e.g. 3) to enable collection.

Optimizer Statistics in MyRocks

This article describes how MyRocks storage engine provides statistics to the query optimizer.

There are three kinds of statistics:

- Table statistics (number of rows in the table, average row size)
- Index cardinality (how distinct values are in the index)
- records-in-range estimates (how many rows are in a certain range “const1 < tbl.key < const2”.

How MyRocks computes statistics

MyRocks (actually RocksDB) uses LSM files which are written once and never updated. When an LSM file is written, MyRocks will compute index cardinalities and number-of-rows for the data in the file. (The file generally has rows, index records and/or tombstones for multiple tables/indexes).

For performance reasons, statistics are computed based on a fraction of rows in the LSM file. The percentage of rows used is controlled by rocksdb_table_stats_sampling_pct; the default value is 10%.

Before the data is dumped into LSM file, it is stored in the MemTable. MemTable doesn’t allow computing index cardinalities, but it can provide an approximate number of rows in the table. Use of MemTable data for statistics is controlled by rocksdb_force_compute_memtable_stats; the default value is `ON`.

Are index statistics predictable?

Those who create/run MTR tests, need to know whether EXPLAIN output is deterministic.
For MyRocks tables, the answer is NO (just like for InnoDB).

Statistics are computed using sampling and GetApproximateMemTableStats() which means that the #rows column in the EXPLAIN output may vary slightly.

Records-in-range estimates

MyRocks uses RocksDB's GetApproximateSizes() call to produce an estimate for the number of rows in the certain range. The data in MemTable is also taken into account by issuing a GetApproximateMemTableStats call.

ANALYZE TABLE

ANALYZE TABLE will possibly flush the MemTable (depending on the rocksdb_flush_memtable_on_analyze and rocksdb_pause_background_work settings).

After that, it will re-read statistics from the SST files and re-compute the summary numbers
(TODO: and if the data was already on disk, the result should not be different from the one we had before ANALYZE?)

Debugging helper variables

There are a few variables that will cause MyRocks to report certain pre-defined estimate numbers to the optimizer:

- @@rocksdb_records_in_range - if not 0, report that any range has this many rows
- @@rocksdb_force_index_records_in_range - if not 0, and FORCE INDEX hint is used, report that any range has this many rows.
- @@rocksdb_debug_optimizer_n_rows - if not 0, report that any MyRocks table has this many rows.

MyRocks Transactional Isolation

- MyRocks uses snapshot isolation.
- Support do `READ-COMMITTED` and `REPEATABLE-READ` .
- `SERIALIZABLE` is not supported.
  - There is no "gap locking" which makes Statement Based Replication unsafe (see MyRocks and Replication).

MyRocks Status Variables

This page documents status variables related to the MyRocks storage engine. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Rocksdb_block_cache_add`

- Description: Number of blocks added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_add_failures`

- Description: Number of failures when adding blocks to Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_bytes_read`

- Description: Bytes read from Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_bytes_write`

- Description: Bytes written to Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_data_add`

- Description: Number of data blocks added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_data_bytes_insert`

- Description: Bytes added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_data_hit`

- Description: Number of hits when accessing the data block from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_data_miss`

- Description: Number of misses when accessing the data block from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_filter_add`

- Description: Number of bloom filter blocks added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_filter_bytes_evict`

- Description: Bytes of bloom filter blocks evicted from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_filter_bytes_insert`

- Description: Bytes of bloom filter blocks added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_filter_hit`

- Description: Number of hits when accessing the filter block from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_filter_miss`

- Description: Number of misses when accessing the filter block from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_hit`

- Description: Total number of hits for the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_index_add`

- Description: Number of index blocks added to Block Cache index.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_index_bytes_evict`

- Description: Bytes of index blocks evicted from the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_index_bytes_insert`

- Description: Bytes of index blocks added to the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_block_cache_index_hit`

- Description: Number of hits for the Block Cache index.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_index_miss`

- Description: Number of misses for the Block Cache index.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cache_miss`

- Description: Total number of misses for the Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cachecompressed_hit`

- Description: Number of hits for the compressed Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_block_cachecompressed_miss`

- Description: Number of misses for the compressed Block Cache.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_bloom_filter_full_positive`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.18, MariaDB 10.3.10

`Rocksdb_bloom_filter_full_true_positive`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.18, MariaDB 10.3.10

`Rocksdb_bloom_filter_prefix_checked`

- Description: Number of times the Bloom Filter checked before creating an iterator on a file.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_bloom_filter_prefix_useful`

- Description: Number of times the Bloom Filter check used to avoid creating an iterator on a file.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_bloom_filter_useful`

- Description: Number of times the Bloom Filter used instead of reading form file.
- Scope: Global, Session

- Data Type: `numeric`

`Rocksdb_bytes_read`

- Description: Total number of uncompressed bytes read from memtables, cache or table files.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_bytes_written`

- Description: Total number of uncompressed bytes written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_compact_read_bytes`

- Description: Number of bytes read during compaction.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_compact_write_bytes`

- Description: Number of bytes written during compaction.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_compaction_key_drop_new`

- Description: Number of keys dropped during compaction due their being overwritten by new values.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_compaction_key_drop_obsolete`

- Description: Number of keys dropped during compaction due to their being obsolete.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_compaction_key_drop_user`

- Description: Number of keys dropped during compaction due to user compaction.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_covered_secondary_key_lookups`

- Description: Incremented when avoiding reading a record via a keyread. This indicates lookups that were performed via a secondary index containing a field that is only a prefix of the VARCHAR column, and that could return all requested fields directly from the secondary index.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_flush_write_bytes`

- Description: Number of bytes written during flush.

- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_get_hit_l0`

- Description: Number of times reads got data from the L0 compaction layer.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_get_hit_l1`

- Description: Number of times reads got data from the L1 compaction layer.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_get_hit_l2_and_up`

- Description: Number of times reads got data from the L2 and up compaction layer.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_getupdatessince_calls`

- Description: Number of calls to the `GetUpdatesSince` function. You may find this useful when monitoring refreshes of the transaction log.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_iter_bytes_read`

- Description: Total uncompressed bytes read from an iterator, including the size of both key and value.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_l0_num_files_stall_micros`

- Description: Shows how long in microseconds throttled due to too many files in L0.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`Rocksdb_l0_slowdown_micros`

- Description: Total time spent waiting in microseconds while performing L0-L1 compactions.
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`Rocksdb_manual_compactions_processed`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.18, MariaDB 10.3.10

`Rocksdb_manual_compactions_running`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.18, MariaDB 10.3.10

`Rocksdb_memtable_compaction_micros`

- Description:
- Scope: Global, Session
- Data Type: `numeric`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`Rocksdb_memtable_hit`

- Description: Number of memtable hits.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_memtable_miss`

- Description: Number of memtable misses.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_memtable_total`

- Description: Memory used, in bytes, of all memtables.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_memtable_unflushed`

- Description: Memory used, in bytes, of all unflushed memtables.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_no_file_closes`

- Description: Number of times files were closed.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_no_file_errors`

- Description: Number of errors encountered while trying to read data from an SST file.

- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_no_file_opens`

- Description: Number of times files were opened.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_num_iterators`

- Description: Number of iterators currently open.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_block_not_compressed`

- Description: Number of uncompressed blocks.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_db_next`

- Description: Number of `next` calls.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_db_next_found`

- Description: Number of `next` calls that returned data.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_db_prev`

- Description: Number of `prev` calls.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_db_prev_found`

- Description: Number of `prev` calls that returned data.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_db_seek`

- Description: Number of `seek` calls.
- Scope: Global, Session

- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_db_seek_found`

- Description: Number of `seek` calls that returned data.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_number_deletes_filtered`

- Description: Number of deleted records were not written to storage due to a nonexistent key.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_keys_read`

- Description: Number of keys have been read.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_keys_updated`

- Description: Number of keys have been updated.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_keys_written`

- Description: Number of keys have been written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_merge_failures`

- Description: Number of failures encountered while performing merge operator actions.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_multiget_bytes_read`

- Description: Number of bytes read during RocksDB `MultiGet()` calls.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_multiget_get`

- Description: Number of RocksDB `MultiGet()` requests made.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_multiget_keys_read`

- Description: Number of keys read through RocksDB `MultiGet()` calls.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_reseeks_iteration`

- Description: Number of reseeks that have occurred inside an iteration that skipped over a large number of keys with the same user key.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_sst_entry_delete`

- Description: Number of delete markers written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_sst_entry_merge`

- Description: Number of merge keys written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_sst_entry_other`

- Description: Number of keys written that are not delete, merge or put keys.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_sst_entry_put`

- Description: Number of put keys written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_sst_entry_singledelete`

- Description: Number of single-delete keys written.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_superversion_acquires`

- Description: Number of times the superversion structure acquired. This is useful when tracking files for the database.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_number_superversion_cleanups`

- Description: Number of times the superversion structure performed cleanups.
- Scope: Global, Session

- Data Type: `numeric`

`Rocksdb_number_superversion_releases`

- Description: Number of times the superversion structure released.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_queries_point`

- Description: Number of single-row queries.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_queries_range`

- Description: Number of multi-row queries.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_row_lock_deadlocks`

- Description: Number of deadlocks.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_row_lock_wait_timeouts`

- Description: Number of row lock wait timeouts.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_rows_deleted`

- Description: Number of rows deleted.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_rows_deleted_blind`

- Description:
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_rows_expired`

- Description: Number of expired rows.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_rows_filtered`

- Description: Number of TTL filtered rows.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.15, MariaDB 10.3.7

`Rocksdb_rows_inserted`

- Description: Number of rows inserted.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_rows_read`

- Description: Number of rows read.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_rows_updated`

- Description: Number of rows updated.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_snapshot_conflict_errors`

- Description: Number of snapshot conflict errors that have occurred during transactions that forced a rollback.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_l0_file_count_limit_slowdowns`

- Description: Write slowdowns due to L0 being near to full.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_l0_file_count_limit_stops`

- Description: Write stops due to L0 being to full.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_locked_l0_file_count_limit_slowdowns`

- Description: Write slowdowns due to L0 being near to full and L0 compaction in progress.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_locked_l0_file_count_limit_stops`

- Description: Write stops due to L0 being full and L0 compaction in progress.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_memtable_limit_slowdowns`

- Description: Write slowdowns due to approaching maximum permitted number of memtables.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.10, MariaDB 10.3.3

`Rocksdb_stall_memtable_limit_stops`

- Description: * Description: Write stops due to reaching maximum permitted number of memtables.
- Scope: Global, Session
- Data Type: `numeric`
- Introduced: MariaDB 10.2.10, MariaDB 10.3.3

`Rocksdb_stall_micros`

- Description: Time in microseconds that the writer had to wait for the compaction or flush to complete.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_pending_compaction_limit_slowdowns`

- Description: Write slowdowns due to nearing the limit for the maximum number of pending compaction bytes.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_pending_compaction_limit_stops`

- Description: Write stops due to reaching the limit for the maximum number of pending compaction bytes.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_total_slowdowns`

- Description: Total number of write slowdowns.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_stall_total_stops`

- Description: Total number of write stops.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_system_rows_deleted`

- Description: Number of rows deleted from system tables.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_system_rows_inserted`

- Description: Number of rows inserted into system tables.
- Scope: Global, Session

- Data Type: `numeric`

`Rocksdb_system_rows_read`

- Description: Number of rows read from system tables.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_system_rows_updated`

- Description: Number of rows updated for system tables.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_wal_bytes`

- Description: Number of bytes written to WAL.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_wal_group_syncs`

- Description: Number of group commit WAL file syncs have occurred. This is provided by MyRocks and is not a view of a RocksDB counter. Increased in `rocksdb_flush_wal()` when doing the `rdb->FlushWAL()` call.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_wal_synced`

- Description: Number of syncs made on RocksDB WAL file.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_write_other`

- Description: Number of writes processed by a thread other than the requesting thread.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_write_self`

- Description: Number of writes processed by requesting thread.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_write_timedout`

- Description: Number of writes that timed out.
- Scope: Global, Session
- Data Type: `numeric`

`Rocksdb_write_wal`

- Description: Number of write calls that requested WAL.

- Scope: Global, Session
- Data Type: `numeric`

MyRocks System Variables

This page documents system variables related to the MyRocks storage engine. See Server System Variables for a complete list of system variables and instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

`rocksdb_access_hint_on_compaction_start`

- Description: DBOptions::access_hint_on_compaction_start for RocksDB. Specifies the file access pattern, applied to all input files, once a compaction starts.
- Command line: `--rocksdb-access-hint-on-compaction-start=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `3`

`rocksdb_advise_random_on_open`

- Description: DBOptions::advise_random_on_open for RocksDB.
- Command line: `--rocksdb-advise-random-on-open={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_allow_concurrent_memtable_write`

- Description: DBOptions::allow_concurrent_memtable_write for RocksDB.
- Command line: `--rocksdb-allow-concurrent-memtable-write={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_allow_mmap_reads`

- Description: DBOptions::allow_mmap_reads for RocksDB
- Command line: `--rocksdb-allow-mmap-reads={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_allow_mmap_writes`

- Description: DBOptions::allow_mmap_writes for RocksDB

- Command line: `--rocksdb-allow-mmap-writes={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_allow_to_start_after_corruption`

- Description: Allow server still to start successfully even if RocksDB corruption is detected.
- Command line: `--rocksdb-allow-to-start-after-corruption={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_background_sync`

- Description: Turns on background syncs for RocksDB
- Command line: `--rocksdb-background-sync={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_base_background_compactions`

- Description: DBOptions::base_background_compactions for RocksDB
- Command line: `--rocksdb-base-background-compactions=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1`
- Range: `-1` to `64`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_blind_delete_primary_key`

- Description: Deleting rows by primary key lookup, without reading rows (Blind Deletes). Blind delete is disabled if the table has secondary key.
- Command line: `--rocksdb-blind-delete-primary-key={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_block_cache_size`

- Description: Block_cache size for RocksDB (block size 1024)
- Command line: `--rocksdb-block-cache-size=#`

- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `536870912`
- Range: `1024` to `9223372036854775807`

To see the statistics of block cache usage, check `SHOW ENGINE ROCKSDB STATUS` output (search for lines starting with `rocksdb.block.cache`).

One can check the size of data of the block cache in `DB_BLOCK_CACHE_USAGE` column of the `INFORMATION_SCHEMA.ROCKSDB_DBSTATS` table.

`rocksdb_block_restart_interval`

- Description: BlockBasedTableOptions::block_restart_interval for RocksDB
- Command line: `--rocksdb-block-restart-interval=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `16`
- Range: `1` to `2147483647`

`rocksdb_block_size`

- Description: BlockBasedTableOptions::block_size for RocksDB
- Command line: `--rocksdb-block-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `4096`
- Range: `1` to `18446744073709551615`

`rocksdb_block_size_deviation`

- Description: BlockBasedTableOptions::block_size_deviation for RocksDB
- Command line: `--rocksdb-block-size-deviation=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `10`
- Range: `0` to `2147483647`

`rocksdb_bulk_load`

- Description: Use bulk-load mode for inserts. This disables unique_checks and enables rocksdb_commit_in_the_middle.
- Command line: `--rocksdb-bulk-load={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_bulk_load_allow_sk`

- Description: Allow bulk loading of sk keys during bulk-load. Can be changed only when bulk load is disabled.
- Command line: `--rocksdb-bulk-load_allow_sk={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_bulk_load_allow_unsorted`

- Description: Allow unsorted input during bulk-load. Can be changed only when bulk load is disabled.
- Command line: `--rocksdb-bulk-load_allow_unsorted={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_bulk_load_size`

- Description: Maximum number of records in a batch for bulk-load mode.
- Command line: `--rocksdb-bulk-load-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1000`
- Range: `1` to `1073741824`

`rocksdb_bytes_per_sync`

- Description: DBOptions::bytes_per_sync for RocksDB.
- Command line: `--rocksdb-bytes-per-sync=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_cache_dump`

- Description: Include RocksDB block cache content in core dump.
- Command line: `--rocksdb-cache-dump={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_cache_high_pri_pool_ratio`

- Description: Specify the size of block cache high-pri pool.
- Command line: `--rocksdb-cache-high-pri-pool-ratio=#`

- Scope: Global
- Dynamic: Yes
- Data Type: `double`
- Default Value: `0.000000`
- Range: `0` to `1`

`rocksdb_cache_index_and_filter_blocks`

- Description: BlockBasedTableOptions::cache_index_and_filter_blocks for RocksDB.
- Command line: `--rocksdb-cache-index-and-filter-blocks={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_cache_index_and_filter_with_high_priority`

- Description: cache_index_and_filter_blocks_with_high_priority for RocksDB.
- Command line: `--rocksdb-cache-index-and-filter-with-high-priority={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_checksums_pct`

- Description: Percentage of rows to be checksummed.
- Command line: `--rocksdb-checksums-pct=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Range: `0` to `100`

`rocksdb_collect_sst_properties`

- Description: Enables collecting SST file properties on each flush.
- Command line: `--rocksdb-collect-sst-properties={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_commit_in_the_middle`

- Description: Commit rows implicitly every rocksdb_bulk_load_size, on bulk load/insert, update and delete.
- Command line: `--rocksdb-commit-in-the-middle={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`

- Default Value: `OFF`

`rocksdb_commit_time_batch_for_recovery`

- Description: TransactionOptions::commit_time_batch_for_recovery for RocksDB.
- Command line: `--rocksdb-commit-time-batch-for-recovery={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_compact_cf`

- Description: Compact column family.
- Command line: `--rocksdb-compact-cf=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_compaction_readahead_size`

- Description: DBOptions::compaction_readahead_size for RocksDB.
- Command line: `--rocksdb-compaction-readahead-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_compaction_sequential_deletes`

- Description: RocksDB will trigger compaction for the file if it has more than this number sequential deletes per window.
- Command line: `--rocksdb-compaction-sequential-deletes=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2000000`

`rocksdb_compaction_sequential_deletes_count_sd`

- Description: Counting SingleDelete as rocksdb_compaction_sequential_deletes.
- Command line: `--rocksdb-compaction-sequential-deletes-count-sd={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_compaction_sequential_deletes_file_size`

- Description: Minimum file size required for compaction_sequential_deletes.
- Command line: `--rocksdb-compaction-sequential-deletes-file-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-1` to `9223372036854775807`

`rocksdb_compaction_sequential_deletes_window`

- Description: Size of the window for counting rocksdb_compaction_sequential_deletes.
- Command line: `--rocksdb-compaction-sequential-deletes-window=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2000000`

`rocksdb_concurrent_prepare`

- Description: DBOptions::concurrent_prepare for RocksDB.
- Command line: `--rocksdb-coconcurrent-prepare={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `1`
- Removed: MariaDB 10.3.7, MariaDB 10.2.15

`rocksdb_create_checkpoint`

- Description: Checkpoint directory.
- Command line: `--rocksdb-create-checkpoint=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_create_if_missing`

- Description: DBOptions::create_if_missing for RocksDB.
- Command line: `--rocksdb-create-if-missing={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_create_missing_column_families`

- Description: DBOptions::create_missing_column_families for RocksDB.

- Command line: `--rocksdb-create-missing-column-families={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_datadir`

- Description: RocksDB data directory.
- Command line: `--rocksdb-datadir[=value]`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `./#rocksdb`

`rocksdb_db_write_buffer_size`

- Description: DBOptions::db_write_buffer_size for RocksDB.
- Command line: `--rocksdb-db-write-buffer-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_deadlock_detect`

- Description: Enables deadlock detection.
- Command line: `--rocksdb-deadlock-detect={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_deadlock_detect_depth`

- Description: Number of transactions deadlock detection will traverse through before assuming deadlock.
- Command line: `--rocksdb-deadlock-detect-depth=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `50`
- Range: `2` to `18446744073709551615`

`rocksdb_debug_manual_compaction_delay`

- Description: For debugging purposes only. Sleeping specified seconds for simulating long running compactions.
- Command line: `--rocksdb-debug_manual_compaction_delay=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4294967295`

`rocksdb_debug_optimizer_no_zero_cardinality`

- Description: If cardinality is zero, override it with some value.
- Command line: `--rocksdb-debug-optimizer-no-zero-cardinality={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_debug_ttl_ignore_pk`

- Description: For debugging purposes only. If true, compaction filtering will not occur on PK TTL data. This variable is a no-op in non-debug builds.
- Command line: `--rocksdb-debug-ttl-ignore-pk={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_debug_ttl_read_filter_ts`

- Description: For debugging purposes only. Overrides the TTL read filtering time to time + debug_ttl_read_filter_ts. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
- Command line: `--rocksdb-debug-ttl-read-filter-ts=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-3600` to `3600`

`rocksdb_debug_ttl_rec_ts`

- Description: For debugging purposes only. Overrides the TTL of records to now() + debug_ttl_rec_ts. The value can be +/- to simulate a record inserted in the past vs a record inserted in the ‘future’. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.
- Command line: `--rocksdb-debug-ttl-read-filter-ts=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-3600` to `3600`

`rocksdb_debug_ttl_snapshot_ts`

- Description: For debugging purposes only. Sets the snapshot during compaction to now() + debug_set_ttl_snapshot_ts. The value can be positive or negative to simulate a snapshot in the past vs a

snapshot created in the 'future'. A value of 0 denotes that the variable is not set. This variable is a no-op in non-debug builds.

- Command line: `--rocksdb-debug-ttl-snapshot-ts=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-3600` to `3600`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_default_cf_options`

- Description: Default cf options for RocksDB.
- Command line: `--rocksdb-default-cf-options=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_delayed_write_rate`

- Description: DBOptions::delayed_write_rate.
- Command line: `--rocksdb-delayed-write-rate=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0` (Previously `16777216`)
- Range: `0` to `18446744073709551615`

`rocksdb_delete_cf`

- Description: Delete column family.
- Command line: `--rocksdb-delete-cf=val`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty string)
- Introduced: MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26

`rocksdb_delete_obsolete_files_period_micros`

- Description: DBOptions::delete_obsolete_files_period_micros for RocksDB.
- Command line: `--rocksdb-delete-obsolete-files-period-micros=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `21600000000`
- Range: `0` to `9223372036854775807`

`rocksdb_enable_2pc`

- Description: Enable two phase commit for MyRocks. When set, MyRocks will keep its data consistent with the binary log (in other words, the server are a crash-safe master). The consistency is achieved by doing two-phase XA commit with the binary log.
- Command line: `--rocksdb-enable-2pc={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_enable_bulk_load_api`

- Description: Enables using SstFileWriter for bulk loading.
- Command line: `--rocksdb-enable-bulk-load-api={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_enable_insert_with_update_caching`

- Description: Whether to enable optimization where we cache the read from a failed insertion attempt in INSERT ON DUPLICATE KEY UPDATE.
- Command line: `--rocksdb-enable-insert-with-update-caching={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26

`rocksdb_enable_thread_tracking`

- Description: DBOptions::enable_thread_tracking for RocksDB.
- Command line: `--rocksdb-enable-thread-tracking={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_enable_ttl`

- Description: Enable expired TTL records to be dropped during compaction.
- Command line: `--rocksdb-enable-ttl={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_enable_ttl_read_filtering`

- Description: For tables with TTL, expired records are skipped/filtered out during processing and in query results. Disabling this will allow these records to be seen, but as a result rows may disappear in the middle of transactions as they are dropped during compaction. Use with caution.
- Command line: `--rocksdb-enable-ttl-read-filtering={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_enable_write_thread_adaptive_yield`

- Description: DBOptions::enable_write_thread_adaptive_yield for RocksDB.
- Command line: `--rocksdb-enable-write-thread-adaptive-yield={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_error_if_exists`

- Description: DBOptions::error_if_exists for RocksDBB.
- Command line: `--rocksdb-error-if-exists={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_error_on_suboptimal_collation`

- Description: Raise an error instead of warning if a sub-optimal collation is used.
- Command line: `--rocksdb-error-on-suboptimal-collation={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.3.10, MariaDB 10.2.18

`rocksdb_flush_log_at_trx_commit`

- Description: Sync on transaction commit. Similar to innodb_flush_log_at_trx_commit. One can check the flushing by examining the rocksdb_wal_synced and rocksdb_wal_bytes status variables.
  - 1: Always sync on commit (the default).
  - 0: Never sync.
  - 2: Sync based on a timer controlled via rocksdb-background-sync.
- Command line: `--rocksdb-flush-log-at-trx-commit=#`
- Scope: Global
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `2`

`rocksdb_flush_memtable_on_analyze`

- Description: Forces memtable flush on ANALYZE table to get accurate cardinality.
- Command line: `--rocksdb-flush-memtable-on-analyze={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Removed: MariaDB 10.3.7, MariaDB 10.2.15

`rocksdb_force_compute_memtable_stats`

- Description: Force to always compute memtable stats.
- Command line: `--rocksdb-force-compute-memtable-stats={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_force_compute_memtable_stats_cachetime`

- Description: Time in usecs to cache memtable estimates.
- Command line: `--rocksdb-force-compute-memtable-stats-cachetime=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `60000000`
- Range: `0` to `2147483647`

`rocksdb_force_flush_memtable_and_lzero_now`

- Description: Acts similar to force_flush_memtable_now, but also compacts all L0 files.
- Command line: `--rocksdb-force-flush-memtable-and-lzero-now={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_force_flush_memtable_now`

- Description: Forces memstore flush which may block all write requests so be careful.
- Command line: `--rocksdb-force-flush-memtable-now={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`

- Default Value: `OFF`

`rocksdb_force_index_records_in_range`

- Description: Used to override the result of records_in_range() when FORCE INDEX is used.
- Command line: `--rocksdb-force-index-records-in-range=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2147483647`

`rocksdb_git_hash`

- Description: Git revision of the RocksDB library used by MyRocks.
- Command line: `--rocksdb-git-hash=value=#`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: As per git revision.

`rocksdb_hash_index_allow_collision`

- Description: BlockBasedTableOptions::hash_index_allow_collision for RocksDB.
- Command line: `--rocksdb-hash-index-allow-collision={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_ignore_unknown_options`

- Description: Enable ignoring unknown options passed to RocksDB.
- Command line: `--rocksdb-ignore-unknown-options={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.3.7, MariaDB 10.2.15

`rocksdb_index_type`

- Description: BlockBasedTableOptions::index_type for RocksDB.
- Command line: `--rocksdb-index-type=value`
- Scope: Global
- Dynamic: No
- Data Type: `enum`
- Default Value: `kBinarySearch`
- Valid Values: `kBinarySearch`, `kHashSearch`

`rocksdb_info_log_level`

- Description: Filter level for info logs to be written mysqld error log. Valid values include 'debug_level', 'info_level', 'warn_level', 'error_level' and 'fatal_level'.
- Command line: `--rocksdb-info-log-level=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `enum`
- Default Value: `error_level`
- Valid Values: `error_level`, `debug_level`, `info_level`, `warn_level`, `fatal_level`

`rocksdb_io_write_timeout`

- Description: Timeout for experimental I/O watchdog.
- Command line: `--rocksdb-io-write-timeout=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Valid Values: `0` to `4294967295`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_is_fd_close_on_exec`

- Description: DBOptions::is_fd_close_on_exec for RocksDB.
- Command line: `--rocksdb-is-fd-close-on-exec={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_keep_log_file_num`

- Description: DBOptions::keep_log_file_num for RocksDB.
- Command line: `--rocksdb-keep-log-file-num=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1000`
- Range: `0` to `18446744073709551615`

`rocksdb_large_prefix`

- Description: Support large index prefix length of 3072 bytes. If off, the maximum index prefix length is 767.
- Command line: `--rocksdb-large_prefix={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_lock_scanned_rows`

- Description: Take and hold locks on rows that are scanned but not updated.
- Command line: `--rocksdb-lock-scanned-rows={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_lock_wait_timeout`

- Description: Number of seconds to wait for lock.
- Command line: `--rocksdb-lock-wait-timeout=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `1073741824`

`rocksdb_log_dir`

- Description: DBOptions::log_dir for RocksDB. Where the log files are stored. An empty value implies `rocksdb_datadir` is used as the directory.
- Command line: `--rocksdb-log-dir=#`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)
- Introduced: MariaDB 10.9.1

`rocksdb_log_file_time_to_roll`

- Description: DBOptions::log_file_time_to_roll for RocksDB.
- Command line: `--rocksdb-log-file-time-to_roll=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_manifest_preallocation_size`

- Description: DBOptions::manifest_preallocation_size for RocksDB.
- Command line: `--rocksdb-manifest-preallocation-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `4194304`
- Range: `0` to `18446744073709551615`

`rocksdb_manual_compaction_threads`

- Description: How many rocksdb threads to run for manual compactions.
- Command line: `--rocksdb-manual-compation-threads=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `128`
- Introduced: MariaDB 10.3.10, MariaDB 10.2.18

`rocksdb_manual_wal_flush`

- Description: DBOptions::manual_wal_flush for RocksDB.
- Command line: `--rocksdb-manual-wal-flush={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_master_skip_tx_api`

- Description: Skipping holding any lock on row access. Not effective on slave.
- Command line: `--rocksdb-master-skip-tx-api={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_max_background_compactions`

- Description: DBOptions::max_background_compactions for RocksDB.
- Command line: `--rocksdb-max-background-compactions=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `64`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_max_background_flushes`

- Description: DBOptions::max_background_flushes for RocksDB.
- Command line: `--rocksdb-max-background-flushes=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `64`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_max_background_jobs`

- Description: DBOptions::max_background_jobs for RocksDB.
- Command line: `--rocksdb-max-background-jobs=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `2`
- Range: `-1` to `64`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_max_latest_deadlocks`

- Description: Maximum number of recent deadlocks to store.
- Command line: `--rocksdb-max-latest-deadlocks=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `5`
- Range: `0` to `4294967295`

`rocksdb_max_log_file_size`

- Description: DBOptions::max_log_file_size for RocksDB.
- Command line: `--rocksdb-max-log-file-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_max_manifest_file_size`

- Description: DBOptions::max_manifest_file_size for RocksDB.
- Command line: `--rocksdb-manifest-log-file-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1073741824`
- Range: `0` to `18446744073709551615`

`rocksdb_max_manual_compactions`

- Description: Maximum number of pending + ongoing number of manual compactions..
- Command line: `--rocksdb-manual_compactions=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Range: `0` to `4294967295`

- Introduced: MariaDB 10.3.10, MariaDB 10.2.18

`rocksdb_max_open_files`

- Description: DBOptions::max_open_files for RocksDB.
- Command line: `--rocksdb-max-open-files=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `-2`
- Range: `-2` to `2147483647`

`rocksdb_max_row_locks`

- Description: Maximum number of locks a transaction can have.
- Command line: `--rocksdb-max-row-locks=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1048576`
- Range:
  - `1` to `1073741824` (>= MariaDB 10.3.10, MariaDB 10.2.18)
  - `1` to `1048576` (<= MariaDB 10.3.9, MariaDB 10.2.17)

`rocksdb_max_subcompactions`

- Description: DBOptions::max_subcompactions for RocksDB.
- Command line: `--rocksdb-max-subcompactions=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1`
- Range: `1` to `64`

`rocksdb_max_total_wal_size`

- Description: DBOptions::max_total_wal_size for RocksDB. The maximum size limit for write-ahead-log files. Once this limit is reached, RocksDB forces the flushing of memtables.
- Command line: `--rocksdb-max-total-wal-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `9223372036854775807`

`rocksdb_merge_buf_size`

- Description: Size to allocate for merge sort buffers written out to disk during inplace index creation.
- Command line: `--rocksdb-merge-buf-size=#`
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `67108864`
- Range: `100` to `18446744073709551615`

`rocksdb_merge_combine_read_size`

- Description: Size that we have to work with during combine (reading from disk) phase of external sort during fast index creation.
- Command line: `--rocksdb-merge-combine-read-size=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1073741824`
- Range: `100` to `18446744073709551615`

`rocksdb_merge_tmp_file_removal_delay_ms`

- Description: Fast index creation creates a large tmp file on disk during index creation. Removing this large file all at once when index creation is complete can cause trim stalls on Flash. This variable specifies a duration to sleep (in milliseconds) between calling chsize() to truncate the file in chunks. The chunk size is the same as merge_buf_size.
- Command line: `--rocksdb-merge-tmp-file-removal-delay-ms=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_new_table_reader_for_compaction_inputs`

- Description: DBOptions::new_table_reader_for_compaction_inputs for RocksDB.
- Command line: `--rocksdb-new-table-reader-for-compaction-inputs={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_no_block_cache`

- Description: BlockBasedTableOptions::no_block_cache for RocksDB.
- Command line: `--rocksdb-no-block-cache={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_override_cf_options`

- Description: Option overrides per cf for RocksDB. Note that the `rocksdb-override-cf-options` syntax is quite strict, and any typos will result in a parse error, and the MyRocks plugin will not be loaded. Depending on your configuration, the server may still start. If it does start, you can use this command to check if the plugin is loaded: `select * from information_schema.plugins where plugin_name='ROCKSDB'` (note that you need the "ROCKSDB" plugin. Other auxiliary plugins like "ROCKSDB_TRX" might still get loaded). Another way is to detect the error is check the error log.
- Command line: `--rocksdb-override-cf-options=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_paranoid_checks`

- Description: DBOptions::paranoid_checks for RocksDB.
- Command line: `--rocksdb-paranoid-checks={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_pause_background_work`

- Description: Disable all rocksdb background operations.
- Command line: `--rocksdb-pause-background-work={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_perf_context_level`

- Description: Perf Context Level for rocksdb internal timer stat collection.
- Command line: `--rocksdb-perf-context-level=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `5`

`rocksdb_persistent_cache_path`

- Description: Path for BlockBasedTableOptions::persistent_cache for RocksDB.
- Command line: `--rocksdb-persistent-cache-path=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_persistent_cache_size_mb`

- Description: Size of cache in MB for BlockBasedTableOptions::persistent_cache for RocksDB.
- Command line: `--rocksdb-persistent-cache-size-mb=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_pin_l0_filter_and_index_blocks_in_cache`

- Description: pin_l0_filter_and_index_blocks_in_cache for RocksDB.
- Command line: `--rocksdb-pin-l0-filter-and-index-blocks-in-cache={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_print_snapshot_conflict_queries`

- Description: Logging queries that got snapshot conflict errors into *.err log.
- Command line: `--rocksdb-print-snapshot-conflict-queries={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_rate_limiter_bytes_per_sec`

- Description: DBOptions::rate_limiter bytes_per_sec for RocksDB.
- Command line: `--rocksdb-rate-limiter-bytes-per-sec=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `9223372036854775807`

`rocksdb_read_free_rpl_tables`

- Description: List of tables that will use read-free replication on the slave (i.e. not lookup a row during replication).
- Command line: `--rocksdb-read-free-rpl-tables=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)
- Removed: MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26

`rocksdb_records_in_range`

- Description: Used to override the result of records_in_range(). Set to a positive number to override.

- Command line: `--rocksdb-records-in-range=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2147483647`

`rocksdb_remove_mariadb-backup_checkpoint`

- Description: Remove mariadb-backup checkpoint.
- Command line: `--rocksdb-remove-mariadb-backup-checkpoint={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.3.8, MariaDB 10.2.16

`rocksdb_reset_stats`

- Description: Reset the RocksDB internal statistics without restarting the DB.
- Command line: `--rocksdb-reset-stats={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_rollback_on_timeout`

- Description: Whether to roll back the complete transaction or a single statement on lock wait timeout (a single statement by default).
- Command line: `--rocksdb-rollback-on-timeout={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26

`rocksdb_seconds_between_stat_computes`

- Description: Sets a number of seconds to wait between optimizer stats recomputation. Only changed indexes are refreshed.
- Command line: `--rocksdb-seconds-between-stat-computes=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `3600`
- Range: `0` to `4294967295`

`rocksdb_signal_drop_index_thread`

- Description: Wake up drop index thread.
- Command line: `--rocksdb-signal-drop-index-thread={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_sim_cache_size`

- Description: Simulated cache size for RocksDB.
- Command line: `--rocksdb-sim-cache-size=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `9223372036854775807`

`rocksdb_skip_bloom_filter_on_read`

- Description: Skip using bloom filter for reads.
- Command line: `--rocksdb-skip-bloom-filter-on_read={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_skip_fill_cache`

- Description: Skip filling block cache on read requests.
- Command line: `--rocksdb-skip-fill-cache={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_skip_unique_check_tables`

- Description: Skip unique constraint checking for the specified tables.
- Command line: `--rocksdb-skip-unique-check-tables=value`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: `.*`

`rocksdb_sst_mgr_rate_bytes_per_sec`

- Description: DBOptions::sst_file_manager rate_bytes_per_sec for RocksDB
- Command line: `--rocksdb-sst-mgr-rate-bytes-per-sec=#`
- Scope: Global

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_stats_dump_period_sec`

- Description: DBOptions::stats_dump_period_sec for RocksDB.
- Command line: `--rocksdb-stats-dump-period-sec=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `600`
- Range: `0` to `2147483647`

`rocksdb_stats_level`

- Description: Statistics Level for RocksDB. Default is 0 (kExceptHistogramOrTimers).
- Command line: `--rocksdb-stats-level=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4`
- Introduced: MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26

`rocksdb_stats_recalc_rate`

- Description: The number of indexes per second to recalculate statistics for. 0 to disable background recalculation.
- Command line: `--rocksdb-stats-recalc_rate=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4294967295`
- Introduced: MariaDB 10.3.10 MariaDB 10.2.18

`rocksdb_store_row_debug_checksums`

- Description: Include checksums when writing index/table records.
- Command line: `--rocksdb-store-row-debug-checksums={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_strict_collation_check`

- Description: Enforce case sensitive collation for MyRocks indexes.

- Command line: `--rocksdb-strict-collation-check={0|1}`
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_strict_collation_exceptions`

- Description: List of tables (using regex) that are excluded from the case sensitive collation enforcement.
- Command line: `--rocksdb-strict-collation-exceptions=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_supported_compression_types`

- Description: Compression algorithms supported by RocksDB. Note that RocksDB does not make use of MariaDB 10.7 compression-plugins.
- Command line: `--rocksdb-supported-compression-types=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: `Snappy,Zlib,ZSTDNotFinal`

`rocksdb_table_cache_numshardbits`

- Description: DBOptions::table_cache_numshardbits for RocksDB.
- Command line: `--rocksdb-table-cache-numshardbits=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `6`
- Range: `0` to `19`

`rocksdb_table_stats_sampling_pct`

- Description: Percentage of entries to sample when collecting statistics about table properties. Specify either 0 to sample everything or percentage [1..100]. By default 10% of entries are sampled.
- Command line: `--rocksdb-table-stats-sampling-pct=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Range: `0` to `100`

`rocksdb_tmpdir`

- Description: Directory for temporary files during DDL operations.
- Command line: `--rocksdb-tmpdir[=value]`

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_trace_sst_api`

- Description: Generate trace output in the log for each call to the SstFileWriter.
- Command line: `--rocksdb-trace-sst-api={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_two_write_queues`

- Description: DBOptions::two_write_queues for RocksDB.
- Command line: `--rocksdb-two-write-queues={0|1}`
- Scope: Global,
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.3.7, MariaDB 10.2.15

`rocksdb_unsafe_for_binlog`

- Description: Allowing statement based binary logging which may break consistency.
- Command line: `--rocksdb-unsafe-for-binlog={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_update_cf_options`

- Description: Option updates per column family for RocksDB.
- Command line: `--rocksdb-update-cf-options=value`
- Scope: Global
- Dynamic: Yes
- Data Type: `varchar`
- Default Value: (Empty)
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_use_adaptive_mutex`

- Description: DBOptions::use_adaptive_mutex for RocksDB.
- Command line: `--rocksdb-use-adaptive-mutex={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`

- Default Value: `OFF`

`rocksdb_use_clock_cache`

- Description: Use ClockCache instead of default LRUCache for RocksDB.
- Command line: `--rocksdb-use-clock-cache={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_use_direct_io_for_flush_and_compaction`

- Description: DBOptions::use_direct_io_for_flush_and_compaction for RocksDB.
- Command line: `--rocksdb-use-direct-io-for-flush-and-compaction={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_use_direct_reads`

- Description: DBOptions::use_direct_reads for RocksDB.
- Command line: `--rocksdb-use-direct-reads={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_use_direct_writes`

- Description: DBOptions::use_direct_writes for RocksDB.
- Command line: `--rocksdb-use-direct-reads={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`
- Removed: MariaDB 10.3.1, MariaDB 10.2.8

`rocksdb_use_fsync`

- Description: DBOptions::use_fsync for RocksDB.
- Command line: `--rocksdb-use-fsync={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_validate_tables`

- Description: Verify all .frm files match all RocksDB tables (0 means no verification, 1 means verify and fail on error, and 2 means verify but continue.
- Command line: `--rocksdb-validate-tables=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `2`

`rocksdb_verify_row_debug_checksums`

- Description: Verify checksums when reading index/table records.
- Command line: `--rocksdb-verify-row-debug-checksums={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_wal_bytes_per_sync`

- Description: DBOptions::wal_bytes_per_sync for RocksDB.
- Command line: `--rocksdb-wal-bytes-per-sync=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `18446744073709551615`

`rocksdb_wal_dir`

- Description: DBOptions::wal_dir for RocksDB. Directory where the write-ahead-log files are stored.
- Command line: `--rocksdb-wal-dir=value`
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Default Value: (Empty)

`rocksdb_wal_recovery_mode`

- Description: DBOptions::wal_recovery_mode for RocksDB. Default is kAbsoluteConsistency. Records that are not yet committed are stored in the Write-Ahead-Log (WAL). If the server is not cleanly shut down, the recovery mode will determine the WAL recovery behavior.
  - 1: kAbsoluteConsistency. Will not start if any corrupted entries (including incomplete writes) are detected (the default).
  - 0: kTolerateCorruptedTailRecords. Ignores any errors found at the end of the WAL
  - 2: kPointInTimeRecovery. Replay of the WAL is halted after finding an error. The system are recovered to the latest consistent point-in-time. Data from a replica can used to replay past the point-in-time.
  - 3: kSkipAnyCorruptedRecords. A risky option where any corrupted entries are skipped while subsequent healthy WAL entries are applied.

- Command line: `--rocksdb-wal-recovery-mode=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `3`

`rocksdb_wal_size_limit_mb`

- Description: DBOptions::WAL_size_limit_MB for RocksDB. Write-ahead-log files are moved to an archive directory once their memtables are flushed. This variable specifies the largest size, in MB, that the archive can be.
- Command line: `--rocksdb-wal-size-limit-mb=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `9223372036854775807`

`rocksdb_wal_ttl_seconds`

- Description: DBOptions::WAL_ttl_seconds for RocksDB. Oldest time, in seconds, that a write-ahead-log file should exist.
- Command line: `--rocksdb-wal-ttl-seconds=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `9223372036854775807`

`rocksdb_whole_key_filtering`

- Description: BlockBasedTableOptions::whole_key_filtering for RocksDB. If set (the default), the bloomfilter to use the whole key (rather than only the prefix) for filtering is enabled. Lookups should use the whole key for matching to make best use of this setting.
- Command line: `--rocksdb-whole-key-filtering={0|1}`
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `ON`

`rocksdb_write_batch_max_bytes`

- Description: Maximum size of write batch in bytes. 0 means no limit.
- Command line: `--rocksdb-write-batch-max-bytes=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`

- Range: `0` to `18446744073709551615`

`rocksdb_write_disable_wal`

- Description: WriteOptions::disableWAL for RocksDB.
- Command line: `--rocksdb-write-disable-wal={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_write_ignore_missing_column_families`

- Description: WriteOptions::ignore_missing_column_families for RocksDB.
- Command line: `--rocksdb-write-ignore-missing-column-families={0|1}`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`rocksdb_write_policy`

- Description: DBOptions::write_policy for RocksDB.
- Command line: `--rocksdb-write-policy=val`
- Scope: Global
- Dynamic: No
- Data Type: `enum`
- Default Value: `write_committed`
- Valid Values: `write_committed`, `write_prepared`, `write_unprepared`
- Introduced: MariaDB 10.3.10, MariaDB 10.2.18

OQGRAPH Overview

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

OQGRAPH is unlike other storage engines, consisting of an entirely different architecture to a regular storage engine such as Aria, MyISAM or InnoDB.

It is intended to be used for retrieving hierarchical information, such as those used for graphs, routes or social relationships, in plain SQL.

Installing

See Installing OQGRAPH. Note that if the query cache is enabled, OQGRAPH will not use it.

Creating a Table

The following documentation is based upon MariaDB 10.0.7 and OQGRAPH v3.

Example with origin and destination nodes only

To create an OQGRAPH v3 table, a backing table must first be created. This backing table will store the actual data, and are used for all INSERTs, UPDATEs and so on. It must be a regular table, not a view. Here's a simple example to start with:

```
CREATE TABLE oq_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)
 VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only OQGRAPH table is created. The CREATE statement must match the format below - any difference will result in an error.

```
CREATE TABLE oq_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

An older format (prior to MariaDB 10.0.7) has the latch field as a SMALLINT rather than a VARCHAR. The format gives an error:

```
CREATE TABLE oq_old (
  latch SMALLINT UNSIGNED NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';

ERROR 1005 (HY000): Can't create table `test`.`oq_old` (errno: 140 "Wrong create options")
```

The old, deprecated format can still be used prior to MariaDB 11.5 if the value of the oqgraph_allow_create_integer_latch system variable is changed from its default, `FALSE`, to `TRUE`.

```
SET GLOBAL oqgraph_allow_create_integer_latch=1;

CREATE TABLE oq_old (
  latch SMALLINT UNSIGNED NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
Query OK, 0 rows affected, 1 warning (0.19 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------------------------------
-------------------------------------------+
| Level   | Code | Message
|
+---------+------+-----------------------------------------------------------------------------------------------
-------------------------------------------+
| Warning | 1287 | 'latch SMALLINT UNSIGNED NULL' is deprecated and are removed in a future release.
Please use 'latch VARCHAR(32) NULL' instead |
+---------+------+-----------------------------------------------------------------------------------------------
-------------------------------------------+
```

Data is only inserted into the backing table, not the OQGRAPH table.

Now, having created the `oq_graph` table linked to a backing table, it is now possible to query the `oq_graph` table directly. The `weight` field, since it was not specified in this example, defaults to `1`.

```
SELECT * FROM oq_graph;
+-------+--------+--------+--------+------+--------+
| latch | origid | destid | weight | seq  | linkid |
+-------+--------+--------+--------+------+--------+
|  NULL |      1 |      2 |      1 | NULL |   NULL |
|  NULL |      2 |      3 |      1 | NULL |   NULL |
|  NULL |      2 |      6 |      1 | NULL |   NULL |
|  NULL |      3 |      4 |      1 | NULL |   NULL |
|  NULL |      4 |      5 |      1 | NULL |   NULL |
|  NULL |      5 |      6 |      1 | NULL |   NULL |
+-------+--------+--------+--------+------+--------+
```

The data here represents one-directional starting and ending nodes. So node 2 has paths to node 3 and node 6, while node 6 has no paths to any other node.

Manipulating Weight

There are three fields which can be manipulated: `origid`, `destid` (the example above uses these two), as well as `weight`. To create a backing table with a `weight` field as well, the following syntax can be used:

```
CREATE TABLE oq2_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  weight DOUBLE NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)
 VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

```
SELECT * FROM oq2_graph;
+-------+--------+--------+--------+------+--------+
| latch | origid | destid | weight | seq  | linkid |
+-------+--------+--------+--------+------+--------+
| NULL  |      1 |      2 |      1 | NULL |   NULL |
| NULL  |      2 |      3 |      1 | NULL |   NULL |
| NULL  |      2 |      6 |     10 | NULL |   NULL |
| NULL  |      3 |      4 |      3 | NULL |   NULL |
| NULL  |      4 |      5 |      1 | NULL |   NULL |
| NULL  |      5 |      6 |      2 | NULL |   NULL |
+-------+--------+--------+--------+------+--------+
```

See OQGRAPH Examples for OQGRAPH usage examples.

Installing OQGRAPH

The Open Query GRAPH computation engine, or OQGRAPH as the engine itself is called, allows you to handle hierarchies (tree structures) and complex graphs (nodes having many connections in several directions).

Installation

The OQGRAPH storage engine exists as a separate package in the repositories. On Ubuntu and Debian the package is called `mariadb-oqgraph-engine-10.0` or `mariadb-plugin-oqgraph`. On Red Hat, CentOS, and Fedora the package is called `MariaDB-oqgraph-engine`. To install the plugin, first install the appropriate package and then install the plugin using the INSTALL SONAME or INSTALL PLUGIN commands.

Debian and Ubuntu

On Debian and Ubuntu, install the package as follows:

```
sudo apt-get install mariadb-oqgraph-engine-10.0
```

Fedora/Red Hat/CentOS

Note that OQGRAPH v3 requires libjudy, which is not in the official Red Hat/Fedora repositories. This needs to be installed first, for example:

```
wget http://dl.fedoraproject.org/pub/epel/6/x86_64/epel-release-6-8.noarch.rpm
rpm -Uvh epel-release-6-8.noarch.rpm
```

Then install the package, as follows:

```
sudo yum install MariaDB-oqgraph-engine
```

Installing the Plugin

On either system you can then launch the `mysql` command-line client and install the plugin in MariaDB as follows:

```
INSTALL SONAME 'ha_oqgraph';
```

See Also

More information on this engine is found on the OpenQuery website: graph-engine

This page is licensed: CC BY-SA / Gnu FDL

Compiling OQGRAPH

To compile OQGraph v2 you need to have the boost library with the versions not earlier than 1.40 and not later than 1.55 and gcc version not earlier than 4.5.

Note

OQGraph v3 compiles fine with the newer boost libraries, but it additionally needs the Judy library installed.

When all build prerequisites are met, OQGraph is enabled and compiled automatically. To enable or disable OQGRAPH explicitly, see the generic plugin build instructions.

Finding Out Why OQGRAPH Didn't Compile

If OQGRAPH gets compiled properly, there should be a file like:

```
storage/oqgraph/ha_oqgraph.so
```

If this is not the case, then you can find out if there is any modules missing that are required by OQGRAPH by doing:

```
cmake . -LAH | grep -i oqgraph
```

This page is licensed: CC BY-SA / Gnu FDL

Building OQGRAPH Under Windows

OQGRAPH v3 can be built on Windows. This has been tested using Windows 7, Microsoft Visual Studio Express 2010 (32-bit), Microsoft Windows 64-bit Platform SDK 7.1 (64-bit), the Boost library >= 1.55 and Judy 1.0.5.

Note

Other recent versions of Boost, Judy or MSVC may work but these combinations have not been tested.

- Download the source package for Boost 1.55 from the Boost project website, www.boost.org
- Download the source package for Judy 1.05 via
- Follow the documented instructions for building under Windows from the command line: Building_MariaDB_on_Windows
  - Ensure that the following variable is set to CMAKE: `JUDY_ROOT=path\to\judy\unzipped`
  - See also comments in `storage/oqgraph/cmake/FindJudy.cmake`

This page is licensed: CC BY-SA / Gnu FDL

OQGRAPH Examples

Creating a Table with origid, destid Only

```
CREATE TABLE oq_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

Some data can be inserted into the backing table to test with later:

```
INSERT INTO oq_backing(origid, destid)
 VALUES (1,2), (2,3), (3,4), (4,5), (2,6), (5,6);
```

Now the read-only OQGRAPH table is created.

You can use the following syntax:

```
CREATE TABLE oq_graph
ENGINE=OQGRAPH
data_table='oq_backing' origid='origid' destid='destid';
```

Creating a Table with Weight

For the examples on this page, we'll create a second OQGRAPH table and backing table, this time with `weight` as well.

```
CREATE TABLE oq2_backing (
  origid INT UNSIGNED NOT NULL,
  destid INT UNSIGNED NOT NULL,
  weight DOUBLE NOT NULL,
  PRIMARY KEY (origid, destid),
  KEY (destid)
);
```

```
INSERT INTO oq2_backing(origid, destid, weight)
 VALUES (1,2,1), (2,3,1), (3,4,3), (4,5,1), (2,6,10), (5,6,2);
```

```
CREATE TABLE oq2_graph (
  latch VARCHAR(32) NULL,
  origid BIGINT UNSIGNED NULL,
  destid BIGINT UNSIGNED NULL,
  weight DOUBLE NULL,
  seq BIGINT UNSIGNED NULL,
  linkid BIGINT UNSIGNED NULL,
  KEY (latch, origid, destid) USING HASH,
  KEY (latch, destid, origid) USING HASH
)
ENGINE=OQGRAPH
data_table='oq2_backing' origid='origid' destid='destid' weight='weight';
```

Shortest Path

A `latch` value of `'dijkstras'` and an `origid` and `destid` is used for finding the shortest path between two nodes, for example:

```
SELECT * FROM oq_graph WHERE latch='breadth_first' AND origid=1 AND destid=6;
+----------+--------+--------+--------+------+--------+
| latch    | origid | destid | weight | seq  | linkid |
+----------+--------+--------+--------+------+--------+
| dijkstras|      1 |      6 |   NULL |    0 |      1 |
| dijkstras|      1 |      6 |      1 |    1 |      2 |
| dijkstras|      1 |      6 |      1 |    2 |      6 |
+----------+--------+--------+--------+------+--------+
```

Note that nodes are uni-directional, so there is no path from node 6 to node 1:

```
SELECT * FROM oq_graph WHERE latch='dijkstras' AND origid=6 AND destid=1;
Empty set (0.00 sec)
```

Using the GROUP_CONCAT function can produce more readable results, for example:

```
SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq_graph
 WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-------+
| path  |
+-------+
| 1,2,6 |
+-------+
```

Using the table `oq2_graph`, the shortest path is different:

```
SELECT GROUP_CONCAT(linkid ORDER BY seq) AS path FROM oq2_graph
 WHERE latch='dijkstras' AND origid=1 AND destid=6;
+-------------+
| path        |
+-------------+
| 1,2,3,4,5,6 |
+-------------+
```

The reason is the weight between nodes 2 and 6 is `10` in `oq_graph2`, so the shortest path taking into account `weight` is now across more nodes.

Possible Destinations

```
SELECT GROUP_CONCAT(linkid) AS dests FROM oq_graph WHERE latch='dijkstras' AND origid=2;
+-----------+
| dests     |
+-----------+
| 5,4,6,3,2 |
+-----------+
```

Note that this returns all possible destinations along the path, not just immediate links.

Leaf Nodes

MariaDB supports the `leaves` latch value. A `latch` value of `'leaves'` and either `origid` or `destid` is used for finding leaf nodes at the beginning or end of a graph.

```
INSERT INTO oq_backing(origid, destid)
 VALUES (1,2), (2,3), (3,5), (4,5), (5,6), (6,7), (6,8), (2,8);
```

For example, to find all reachable nodes from `origid` that only have incoming edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND origid=2;
+--------+--------+--------+--------+------+--------+
| latch  | origid | destid | weight | seq  | linkid |
+--------+--------+--------+--------+------+--------+
| leaves |      2 |   NULL |      4 |    2 |      7 |
| leaves |      2 |   NULL |      1 |    1 |      8 |
+--------+--------+--------+--------+------+--------+
```

And to find all nodes from which a path can be found to `destid` that only have outgoing edges:

```
SELECT * FROM oq_graph WHERE latch='leaves' AND destid=5;
+--------+--------+--------+--------+------+--------+
| latch  | origid | destid | weight | seq  | linkid |
+--------+--------+--------+--------+------+--------+
| leaves |   NULL |      5 |      3 |    2 |      1 |
| leaves |   NULL |      5 |      1 |    1 |      4 |
+--------+--------+--------+--------+------+--------+
```

Summary of Implemented Latch Commands

Latch	Alternative	additional where clause fields	Graph operation
NULL	(unspecified)	(none)	List original data
(empty string)	0	(none extra)	List all vertices in linkid column
(empty string)	0	origid	List all first hop vertices from origid in linkid column
dijkstras	1	origid, destid	Find shortest path using Dijkstras algorithm between origid and destid, with traversed vertex ids in linkid column
dijkstras	1	origid	Find all vertices reachable from origid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight
dijkstras	1	destid	Find all vertices from which a path can be found to destid, listed in linkid column, and report sum of weights of vertices on path to given vertex in weight

Latch	Alternative	additional where clause fields	Graph operation
breadth_first	2	origid	List vertices reachable from origid in linkid column
breadth_first	2	destid	List vertices from which a path can be found to destid in linkid column
breadth_first	2	origid, destid	Find shortest path between origid and destid, report in linkid column
leaves	4	origid	List vertices reachable from origid, that only have incoming edges
leaves	4	destid	List vertices from which a path can be found to destid, that only have outgoing edges
leaves	4	origid, destid	Not supported, will return an empty result

Note

The use of integer latch commands is deprecated and may be phased out in a future release. Currently, numeric values in the strings are interpreted as aliases, and use of an integer column can be optionally allowed, for the latch commands column.

The use of integer latches is controlled using the oqgraph_allow_create_integer_latch system variable.

PERFORMANCE_SCHEMA

If you run SHOW ENGINES, you'll see the following storage engine listed.

```
SHOW ENGINES\G
...
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
...
```

The PERFORMANCE_SCHEMA is not a regular storage engine for storing data, it's a mechanism for implementing the Performance Schema feature.

The SHOW ENGINE PERFORMANCE_SCHEMA STATUS statement is also available, which shows how much memory is used by the tables and internal buffers.

See Performance Schema for more details.

This page is licensed: CC BY-SA / Gnu FDL

SEQUENCE Storage Engine

This article is about the Sequence storage engine. For details about sequence objects, see Sequences.

A **Sequence** engine allows the creation of ascending or descending sequences of numbers (positive integers) with a given starting value, ending value and increment.

It creates completely virtual, ephemeral tables automatically when you need them. There is no way to create a Sequence table explicitly. Nor are they ever written to disk or create `.frm` files. They are read-only, transactional, and support XA.

Installing

The Sequence engine is installed by default, and SHOW ENGINES will list the Sequence storage engine as supported:

```
SHOW ENGINES\G
...
*************************** 5. row ***************************
      Engine: MyISAM
     Support: YES
     Comment: MyISAM storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 6. row ***************************
      Engine: SEQUENCE
     Support: YES
     Comment: Generated tables filled with sequential values
Transactions: YES
          XA: YES
  Savepoints: YES
*************************** 7. row ***************************
      Engine: MRG_MyISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO

...
```

Usage and Examples

To use a Sequence table, you simply select from it, as in

```
SELECT * FROM seq_1_to_5;
+-----+
| seq |
+-----+
|   1 |
|   2 |
|   3 |
|   4 |
|   5 |
+-----+
```

To use a sequence in a statement, you select from the table named by a pattern **seq**_`FROM`***to***`TO` or **seq**_`FROM`***to***`TO`***step***`STEP`.

In the case of an odd step, the sequence will commence with the `FROM`, and end at the final result before `TO`.

```
SELECT * FROM seq_1_to_15_step_3;
+-----+
| seq |
+-----+
|   1 |
|   4 |
|   7 |
|  10 |
|  13 |
+-----+
```

A sequence can go backwards too. In this case the final value will always be the `TO` value, so that a descending sequence has the same values as an ascending sequence:

```
SELECT * FROM seq_5_to_1_step_2;
+-----+
| seq |
+-----+
|   5 |
|   3 |
|   1 |
+-----+
```

```
SELECT * FROM seq_15_to_1_step_3;
+-----+
| seq |
+-----+
|  13 |
|  10 |
|   7 |
|   4 |
|   1 |
+-----+
```

```
SELECT * FROM seq_15_to_2_step_3;
+-----+
| seq |
+-----+
|  14 |
|  11 |
|   8 |
|   5 |
|   2 |
+-----+
```

This engine is particularly useful with joins and subqueries. For example, this query finds all prime numbers below 50:

```
SELECT seq FROM seq_2_to_50 s1 WHERE 0 NOT IN
     (SELECT s1.seq % s2.seq FROM seq_2_to_50 s2 WHERE s2.seq <= sqrt(s1.seq));
+-----+
| seq |
+-----+
|   2 |
|   3 |
|   5 |
|   7 |
|  11 |
|  13 |
|  17 |
|  19 |
|  23 |
|  29 |
|  31 |
|  37 |
|  41 |
|  43 |
|  47 |
+-----+
```

And almost (without 2, the only even prime number) the same result with joins:

```
SELECT s1.seq FROM seq_2_to_50 s1 JOIN seq_2_to_50 s2
  WHERE s1.seq > s2.seq AND s1.seq % s2.seq <> 0
  GROUP BY s1.seq HAVING s1.seq - COUNT(*) = 2;
+-----+
| seq |
+-----+
|   3 |
|   5 |
|   7 |
|  11 |
|  13 |
|  17 |
|  19 |
|  23 |
|  29 |
|  31 |
|  37 |
|  41 |
|  43 |
|  47 |
+-----+
```

Sequence tables can also be useful in date calculations. For example, to find the day of the week that a particular date has fallen on over a 40 year period (perhaps for birthday planning ahead!):

```
SELECT DAYNAME('1980-12-05' + INTERVAL (seq) YEAR) day,
    '1980-12-05' + INTERVAL (seq) YEAR DATE FROM seq_0_to_40;
+-----------+------------+
| day       | date       |
+-----------+------------+
| Friday    | 1980-12-05 |
| Saturday  | 1981-12-05 |
| Sunday    | 1982-12-05 |
...
| Friday    | 2014-12-05 |
| Saturday  | 2015-12-05 |
| Monday    | 2016-12-05 |
| Tuesday   | 2017-12-05 |
| Wednesday | 2018-12-05 |
| Thursday  | 2019-12-05 |
| Saturday  | 2020-12-05 |
+-----------+------------+
```

Although Sequence tables can only directly make use of positive integers, they can indirectly be used to return negative results by making use of the CAST statement:

```
SELECT CAST(seq AS INT) - 5 x FROM seq_5_to_1;
+----+
| x  |
+----+
|  0 |
| -1 |
| -2 |
| -3 |
| -4 |
+----+
```

CAST is required to avoid a `BIGINT UNSIGNED value is out of range` error.

Sequence tables, while virtual, are still tables, so they must be in a database. This means that a default database must be selected (for example, via the USE command) to be able to query a Sequence table. The information_schema database cannot be used as the default for a Sequence table.

Table Name Conflicts

If the SEQUENCE storage engine is installed, it is not possible to create a table with a name which follows the SEQUENCE pattern:

```
CREATE TABLE seq_1_to_100 (col INT) ENGINE = InnoDB;
ERROR 1050 (42S01): Table 'seq_1_to_100' already exists
```

However, a SEQUENCE table can be converted to another engine and the new table can be referred in any statement:

```
ALTER TABLE seq_1_to_100 ENGINE = BLACKHOLE;

SELECT * FROM seq_1_to_100;
Empty set (0.00 sec)
```

While a SEQUENCE table cannot be dropped, it is possible to drop the converted table. The SEQUENCE table with the same name will still exist:

```
DROP TABLE seq_1_to_100;

SELECT COUNT(*) FROM seq_1_to_100;
+----------+
| COUNT(*) |
+----------+
|      100 |
+----------+
1 row in set (0.00 sec)
```

A temporary table with a SEQUENCE-like name can always be created and used:

```
CREATE TEMPORARY TABLE seq_1_to_100 (col INT) ENGINE = InnoDB;

SELECT * FROM seq_1_to_100;
Empty set (0.00 sec)
```

S3 Storage Engine

See Using the S3 Storage Engine.

This guide covers typical use cases for the S3 engine, such as archiving inactive tables, and details supported operations like ALTER TABLE and SELECT.

See S3 Status Variables.

A list of status variables for monitoring the S3 engine's interactions with the cloud service, although specific variables are not extensively documented here.

See S3 System Variables.

This page lists system variables to configure the S3 engine, including AWS credentials, bucket names, page cache sizes, and connection protocols.

See S3 Engine Internals.

Learn about the internal architecture of the S3 engine, which inherits from Aria code but redirects reads to S3, using a dedicated page cache.

See Testing Connections to S3.

Instructions on how to verify your S3 configuration using tools like `aria_s3_copy` and the `mysql-test-run` suite to ensure proper connectivity.

See aria_s3_copy.

A reference for the `aria_s3_copy` tool, which is used to manually copy Aria tables to and from S3 storage for testing and data migration.

This page is licensed: CC BY-SA / Gnu FDL

Using the S3 Storage Engine

The S3 storage engine is read only and allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API (of which there are many), but still have them accessible for reading in MariaDB.

Installing the Plugin

The S3 storage engine is gamma maturity, so the following step can be omitted.

On earlier releases, when it was alpha maturity, it does not load by default on a stable release of the server due to the default value of the plugin_maturity variable. Set to `alpha` (or below) in your config file to permit installation of the plugin:

```
[mariadbd]
plugin-maturity = alpha
```

and restart the server.

Now install the plugin library, for example:

```
INSTALL SONAME 'ha_s3';
```

If the library is not available, for example:

```
INSTALL SONAME 'ha_s3';
ERROR 1126 (HY000): Can't open shared library '/var/lib/mysql/lib64/mysql/plugin/ha_s3.so'
  (errno: 13, cannot open shared object file: No such file or directory)
```

you may need to install a separate package for the S3 storage engine, for example:

```
shell> yum install MariaDB-s3-engine
```

or for Debian/Ubuntu

```
shell> apt install mariadb-plugin-s3
```

Creating an S3 Table

As S3 tables are read only, one cannot create a S3 table with `CREATE TABLE`. You should use instead use `ALTER TABLE old_table ENGINE=S3` to convert an existing table to be stored on S3.

Moving Data to S3

To move data from an existing table to S3, you can run:

```
ALTER TABLE old_table ENGINE=S3 COMPRESSION_ALGORITHM=zlib
```

To get data back to a 'normal' table, you can do:

```
ALTER TABLE s3_table ENGINE=INNODB
```

New Options for ALTER TABLE

- `S3_BLOCK_SIZE` : Set to 4M as default. This is the block size for all index and data pages stored in S3.
- `COMPRESSION_ALGORITHM` : Set to 'none' as default. Which compression algorithm to use for block stored in S3. Options are: `none` or `zlib`.

ALTER TABLE can be used on S3 tables as normal to add columns or change column definitions.

mariadbd Startup Options for S3

To be able to use S3 for storage one ***must*** define how to access S3 and where data are stored in S3:

- s3_access_key: The AWS access key to access your data
- s3_secret_key: The AWS secret key to access your data
- s3_bucket: The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket.
- s3_region: The AWS region where your data should be stored.

For compatibility tweaks with different providers:

- s3_provider: Enable S3 provider specific compatibility tweaks. "Default", "Amazon", or "Huawei". From MariaDB 11.6.2.

If you are using an S3 service that is using HTTP to connect (like) you also need the set the following variables:

- s3_port: Port number to connect to (0 means use default)
- s3_use_http: If true, force use of HTTP protocol

If you are going to use a primary-replica setup, you should look at the following variables:

- s3_replicate_alter_as_create_select: When converting an S3 table to local table, log all rows in binary log. Defaults to `TRUE`. This allows the replica to replicate `CREATE TABLE .. SELECT FROM s3_table` even it the

replica doesn't have access to the original `s3_table`.

- s3_slave_ignore_updates: Should be set if primary and replica share the same S3 instance. This tells the replica that it can ignore any updates to the S3 tables as they are already applied on the primary. Defaults to `FALSE`.

The above defaults assume that the primary and replica don't share the same S3 instance.

Other, less critical options, are:

- s3_host_name: Hostname for the S3 service. "s3.amazonaws.com", Amazon S3 service, by default.
- s3_protocol_version: Protocol used to communication with S3. One of "Auto", "Amazon" or "Original" where "Auto" is the default. If you get errors like "8 Access Denied" when you are connecting to another service provider, then try to change this option. The reason for this variable is that Amazon has changed some parts of the S3 protocol since they originally introduced it but other service providers are still using the original protocol.
- s3_block_size: Set to 4M as default. This is the default block size for a table, if not specified in CREATE TABLE.
- s3_pagecache_buffer_size: Default 128M. The size of the buffer used for data and index blocks for S3 tables. Increase this to get better index handling (for all reads and multiple writes) to as much as you can afford.
- s3_ssl_no_verify: If true, SSL certificate verification for the S3 endpoint is disabled. From MariaDB 11.6.2.
- ss3_no_content_type: If true (false is default), disables the Content-Type header, required for some providers. From MariaDB 11.6.2.

Last some options you probably don't have to ever touch:

- s3_pagecache_age_threshold : Default 300: This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.
- s3_pagecache_division_limit: Default 100. The minimum percentage of warm blocks in key cache.
- s3_pagecache_file_hash_size: Default 512. Number of hash buckets for open files. If you have a lot of S3 files open you should increase this for faster flush of changes. A good value is probably 1/10 of number of possible open S3 files.
- s3_debug: Default 0. Generates a trace file from libmarias3 on stderr (mysqld.err) for debugging the S3 protocol.

Typical my.cnf Entry for connecting to Amazon S3 service

```
[mariadb]
s3=ON
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-http=ON

# Primary and replica share same S3 tables.
s3-slave-ignore-updates=1

[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
s3-host-name=s3.amazonaws.com
# The following is useful if you want to use minio as a S3 server. (https://min.io/)
#s3-port=9000
#s3-use-http=ON
```

Typical my.cnf entry for connecting to a minio S3 server

```
[mariadb]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-http=ON

[aria_s3_copy]
s3=ON
s3-host-name="127.0.0.1"
s3-bucket=storage-engine
s3-access-key=minio
s3-secret-key=minioadmin
s3-port=9000
s3-use-http=ON
```

Typical Usage Case for S3 Tables

The typical use case would be that there exists tables that after some time would become fairly inactive, but are still important so that they can not be removed. In that case, an option is to move such a table to an archiving service, which is accessible through an S3 API.

Notice that S3 means the Cloud Object Storage API defined by Amazon AWS. Often the whole of Amazon's Cloud Object Storage is referred to as S3. In the context of the S3 archive storage engine, it refers to the API itself that defines how to store objects in a cloud service, being it Amazon's or someone else's. OpenStack for example provides an S3 API for storing objects.

The main benefit of storing things in an S3 compatible storage is that the cost of storage is much cheaper than many other alternatives. Many S3 implementations also provide reliable long-term storage.

Operations Allowed on S3 Tables

- ALTER TABLE S3 supports all types, keys and other options that are supported by the Aria engine. One can also perform ALTER TABLE on an S3 table to add or modify columns etc.
- DROP TABLE
- SELECT Any SELECT operations you can perform on a normal table should work with an S3 table.
- SHOW TABLES will show all tables that exist in the current defined S3 location.
- S3 tables can be part of partitions. See Discovery below.

Discovery

The S3 storage engine supports full MariaDB discovery. This means that if you have the S3 storage engine enabled and properly configured, the table stored in S3 will automatically be discovered when it's accessed with SHOW TABLES, SELECT or any other operation that tries to access it. In the case of SELECT, the .frm file from S3 will be copied to the local storage to speed up future accesses.

When an S3 table is opened for the first time (it's not in the table cache) and there is a local .frm file, the S3 engine will check if it's still relevant, and if not, update or delete the .frm file.

This means that if the table definition changes on S3 and it's in the local cache, one has to execute FLUSH TABLES to get MariaDB to notice the change and update the .frm file.

If partitioning S3 tables are used, the partition definitions will also be stored on S3 storage and are discovered by other servers.

Discovery of S3 tables is not done for tables in the mysql databases to make mariadbd boot faster and more securely.

Replication

S3 works with replication. One can use replication in two different scenarios:

- The primary and replica share the same S3 storage. In this case the primary will make all changes to the S3 data and the replica will ignore any changes in the replication stream to S3 data . This scenario is achieved by setting s3_slave_ignore_updates to 1.
- The primary and replica don't share the same S3 storage or the replica uses another storage engine for the S3 tables. This scenario is achieved by setting s3_slave_ignore_updates to 0.

aria_s3_copy

aria_s3_copy is an external tool that one can use to copy Aria tables to and from S3. Use `aria_s3_copy --help` to get the options of how to use it.

mariadb-dump

- mariadb-dump will by default ignore S3 tables. If `mariadb-dump` is run with the `--copy-s3-tables` option, the resulting file will contain a CREATE statement for a similar Aria table, followed by the table data and ending with an `ALTER TABLE xxx ENGINE=S3`.

ANALYZE TABLE

As of MariaDB 10.5.14, ANALYZE TABLE is supported for S3 tables.
As the S3 tables are read-only, a normal `ANALYZE TABLE` will not do anything. However using `ANALYZE TABLE table_name PERSISTENT FOR...` will now work.

CHECK TABLE

As of MariaDB 10.5.14, CHECK TABLE will work. As S3 tables are read only it is very unlikely that they can become corrupted. The only known way an S3 table could be corrupted if either the original table copied to S3 was corrupted or the process of copying the original table to S3 was somehow interrupted.

Current Limitations

- mysql-test-run doesn't by default test the S3 engine as we can't embed AWS keys into mysql-test-run.
- Replicas should not access S3 tables while they are ALTERed! This is because there is no locking implemented to S3 between servers. However, after a table (either the original S3 table or the partitioned S3 table) is changed on the primary, the replica will notice this on the next access and update its local definition.

Limitations in ALTER .. PARTITION

All ALTER PARTITION operations are supported on S3 partitioning tables except:

- REBUILD PARTITION
- TRUNCATE PARTITION
- REORGANIZE PARTITION

Performance Considerations

Depending on your connection speed to your S3 provider, there can be some notable slowdowns in some operations.

Discovery

As S3 is supporting discovery (automatically making tables available that are in S3) this can cause some small performance problems if the S3 engine is enabled. Partitioning S3 tables also support discovery.

- CREATE TABLE is a bit slower as the S3 engine has to check if the to-be-created table is already S3.
- Queries on information_schema tables are slower as S3 has to check if there is new tables in S3.
- DROP of non existing tables are slower as S3 has to check if the table is in S3.

There are no performance degradation's when accessing existing tables on the server. Accessing the S3 table the first time will copy the .frm file from S3 to the local disk, speeding up future accesses to the table.

Caching

- Accessing a table on S3 can take some time , especially if you are using big packets (s3_block_size). However the second access to the same data should be fast as it's then cached in the S3 page cache.

Things to Try to Increase Performance

If you have performance problems with the S3 engine, here are some things you can try:

- Decreasing s3_block_size. This can be done both globally and per table.
- Use COMPRESSION_ALGORITHM=zlib when creating the table. This will decrease the amount of data transferred from S3 to the local cache.
- Increasing the size of the s3 page cache: s3_pagecache_buffer_size

Try also to execute the query twice to check if the problem is that the data was not properly cached. When data is cached locally the performance should be excellent.

Future Development Ideas

- Store aws keys and region in the mysql.servers table (as Spider and FederatedX). This will allow one to have different tables on different S3 servers.
- Store s3 bucket, access_key and secret key in a cache to better be able to better to reuse connections. This would save some memory and make some S3 accesses a bit faster as we could reuse old connections.

Troubleshooting S3 on SELinux

If you get errors such as:

```
ERROR 3 (HY000): Got error from put_object(bubu/produkt/frm): 5 Couldn't connect to server
```

one reason could be that your system doesn't allow MariaDB to connect to ports other than 3306.
To procedure to enable other ports is the following:

Search for the ports allowed for MariaDB:

```
$ sudo semanage port -l | grep mysqld_port_t
mysqld_port_t                tcp   1186, 3306, 63132-63164
```

Say you want to allow MariaDB to connect to port 32768:

```
$ sudo semanage port -a -t mysqld_port_t -p tcp 32768
```

You can verify that the new port, 32768, is now allowed for MariaDB:

```
$ sudo semanage port -l | grep mysqld_port_t
mysqld_port_t                tcp   32768,1186, 3306, 63132-63164
```

S3 Status Variables

> **Note:**
>
> The S3 storage engine is available from MariaDB 10.5.4.

This page documents status variables related to the S3 storage engine. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`S3_pagecache_blocks_not_flushed`

- Description:
- Scope:
- Data Type:
- Introduced: MariaDB 10.5

`S3_pagecache_blocks_unused`

- Description:
- Scope:
- Data Type:
- Introduced: MariaDB 10.5

`S3_pagecache_blocks_used`

- Description:
- Scope:
- Data Type:
- Introduced: MariaDB 10.5

`S3_pagecache_reads`

- Description:
- Scope:
- Data Type:
- Introduced: MariaDB 10.5

S3 System Variables

> **Note:**
>
> The S3 storage engine is available from MariaDB 10.5.4.

This page documents system variables related to the S3 storage engine.

See Server System Variables for a complete list of system variables and instructions on setting system variables.

Also see the Full list of MariaDB options, system and status variables

Variables

`s3_access_key`

- Description: The AWS access key to access your data. See mariadbd startup options for S3.
- Command line: `--s3-access-key=val`
- Scope: Global
- Dynamic: No
- Data Type: String
- Default Value: (Empty)
- Introduced: MariaDB 10.5.4

`s3_block_size`

- Description: The default block size for a table, if not specified in CREATE TABLE. Set to 4M as default. See mariadbd startup options for S3.
- Command line: `--s3-block-size=#`
- Scope: Global
- Dynamic: Yes
- Data Type: Numeric
- Default Value: `4194304`
- Range: `4194304` to `16777216`
- Introduced: MariaDB 10.5.4

`s3_bucket`

- Description: The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket. See mariadbd startup options for S3.
- Command line: `--s3-bucket=val`
- Scope: Global
- Dynamic: No
- Data Type: String
- Default Value: `MariaDB`
- Introduced: MariaDB 10.5.4

`s3_debug`

- Description: Generates a trace file from libmarias3 on stderr (mysqld.err) for debugging the S3 protocol.
- Command line: `--s3-debug=[0|1]`
- Scope: Global
- Dynamic:
  - Yes (>= MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1)
  - No (<= MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3, MariaDB 11.2.2, MariaDB 11.3.1)
- Data Type: Boolean
- Valid Values: 0 or 1
- Default Value: `0`

- Introduced: MariaDB 10.5.4

`s3_host_name`

- Description: Hostname for the S3 service. “s3.amazonaws.com”, Amazon S3 service, by default
- Command line: `--s3-host-name=val`
- Scope: Global
- Dynamic: No
- Data Type: String
- Default Value: `s3.amazonaws.com`
- Introduced: MariaDB 10.5.4

`s3_no_content_type`

- Description: If true (false is default), disables the Content-Type header, required for some providers.
- Command line: `--s3-no-content-type=[0|1]`
- Scope: Global
- Dynamic: No
- Data Type: Boolean
- Default Value: `0`
- Introduced: MariaDB 11.6.2

`s3_pagecache_age_threshold`

- Description: This characterizes the number of hits a hot block has to be untouched until it is considered aged enough to be downgraded to a warm block. This specifies the percentage ratio of that number of hits to the total number of blocks in the page cache.
- Command line: `--s3-pagecache-age-threshold=val`
- Scope: Global
- Dynamic: Yes
- Data Type: Numeric
- Default Value: `300`
- Range: `100` to `18446744073709551615`
- Introduced: MariaDB 10.5.4

`s3_pagecache_buffer_size`

- Description: The size of the buffer used for index blocks for S3 tables. Increase this to get better index handling (for all reads and multiple writes) to as much as you can afford. Size can be adjusted in blocks of `8192`.
- Command line: `--s3-pagecache-buffer-size=val`
- Scope: Global
- Dynamic: No
- Data Type: Numeric
- Default Value: `134217728` (128M)
- Range: `33554432` to `18446744073709551615`
- Introduced: MariaDB 10.5.4

`s3_pagecache_division_limit`

- Description: The minimum percentage of warm blocks in key cache.

- Command line: `--s3-pagecache-division-limit=val`
- Scope: Global
- Dynamic: Yes
- Data Type: Numeric
- Default Value: `100`
- Range: `1` to `100`
- Introduced: MariaDB 10.5.4

`s3_pagecache_file_hash_size`

- Description: Number of hash buckets for open files. Default 512. If you have a lot of S3 files open you should increase this for faster flush of changes. A good value is probably 1/10 of number of possible open S3 files.
- Command line: `--s3-pagecache-file-hash-size=#`
- Scope: Global
- Dynamic: No
- Data Type: Numeric
- Default Value: `512`
- Range: `32` to `16384`
- Introduced: MariaDB 10.5.4

`s3_port`

- Description: The TCP port number on the S3 host to connect to. A values of 0 means determine automatically.
- Command line: `--s3-port=#`
- Scope: Global
- Dynamic: No
- Data Type: Numeric
- Default Value: `0`
- Range: `0` to `65535`
- Introduced: MariaDB 10.5.7

`s3_protocol_version`

- Description: Protocol used to communication with S3. “Auto” is the default. If you get errors like “8 Access Denied” when you are connecting to another service provider, then try to change this option. The reason for this variable is that Amazon has changed some parts of the S3 protocol since they originally introduced it but other service providers are still using the original protocol. Can also be set numerically.
  - `Auto` (`0`):
  - `Original` or (`1`): Same as “Auto”. Deprecated from MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1.
  - `Amazon` (`2`) Same as “Auto”. Deprecated from MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1.
  - `Legacy` (`3`): v1 protocol. From MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1
  - `Path` (`4`): From MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1
  - `Domain` (`5`): From MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1
- Command line: `--s3-protocol-version=val`

- Scope: Global
- Dynamic: Yes
- Data Type: Enum
- Valid Values:
  - `Auto` (`0`), `Original` (`1`), `Amazon` (`2`), `Legacy` (`3`), `Path` (`4`), `Domain` (`5`) (>= MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3, MariaDB 11.3.2, MariaDB 11.4.1)
  - `Auto`, `Original`, `Amazon` (<= MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3, MariaDB 11.2.2, MariaDB 11.3.1)
- Default Value: `Auto`
- Introduced: MariaDB 10.5.4

`s3_provider`

- Description: Enable S3 provider specific compatibility tweaks. “Default”, “Amazon”, or “Huawei”.
  - `Default`:
  - `Amazon`: Effectively sets s3_protocol_version to `5` (`Domain`), overriding any other setting it may have.
  - `Huawei`: Effectively sets s3_no_content_type to 1, overriding any other setting it may have.
- Command line: `--s3-provider=val`
- Scope: Global
- Dynamic: Yes
- Data Type: enum
- Valid Values: `Default`, `Amazon`, `Huawei`
- Default Value: `Default`
- Introduced: MariaDB 10.6.20, MariaDB 10.11.10, MariaDB 11.2.6, MariaDB 11.4.4, MariaDB 11.6.2

`s3_region`

- Description: The AWS region where your data should be stored. See mariadbd startup options for S3.
- Command line: `--s3-region=val`
- Scope: Global
- Dynamic: No
- Data Type: String
- Default Value: (Empty)
- Introduced: MariaDB 10.5.4

`s3_replicate_alter_as_create_select`

- Description: When converting S3 table to local table, log all rows in binary log. This allows the slave to replicate `CREATE TABLE .. SELECT FROM s3_table` even it the slave doesn’t have access to the original `s3_table`.
- Command line: `--s3-replicate-alter-as-create-select=[0|1]`
- Scope: Global
- Dynamic: No
- Data Type: Boolean
- Default Value: `1`
- Introduced: MariaDB 10.5.4

`s3_secret_key`

- Description: The AWS secret key to access your data. See mariadbd startup options for S3.

- Command line: `--s3-secret-key=val`
- Scope: Global
- Dynamic: No
- Data Type: String
- Default Value: (Empty)
- Introduced: MariaDB 10.5.4

`s3_slave_ignore_updates`

- Description: Should be set if master and slave share the same S3 instance. This tells the slave that it can ignore any updates to the S3 tables as they are already applied on the master.
- Command line: `--s3-slave-ignore-updates=[0|1]`
- Scope: Global
- Dynamic: No
- Data Type: Boolean
- Default Value: `0`
- Introduced: MariaDB 10.5.4

`s3_ssl_no_verify`

- Description: If true, SSL certificate verification for the S3 endpoint is disabled
- Command line: `--s3-ssl-no-verify=[0|1]`
- Scope: Global
- Dynamic: No
- Data Type: Boolean
- Default Value: `0`
- Introduced: MariaDB 10.6.20, MariaDB 10.11.10, MariaDB 11.2.6, MariaDB 11.4.4, MariaDB 11.6.2

`s3_use_http`

- Description: If enabled, HTTP are used instead of HTTPS.
- Command line: `--s3-use-http=[0|1]`
- Scope: Global
- Dynamic: No
- Data Type: Boolean
- Default Value: `0`
- Introduced: MariaDB 10.5.7

Using the S3 Storage Engine

This page is licensed: CC BY-SA / Gnu FDL

S3 Engine Internals

> **Note:**
>
> The S3 storage engine is available from MariaDB 10.5.4.

The S3 storage engine is based on the Aria code. Internally, the S3 storage inherits from the Aria code, with hooks that change reads, so that instead of reading data from the local disk it reads things from S3.

The S3 engine uses it's own page cache, modified to be able to handle reading blocks from S3 (of size `s3_block_size`). Internally the S3 page cache uses pages of aria-block-size for splitting the blocks read from S3.

ALTER TABLE

ALTER TABLE will first create a local table in the normal Aria on disk format and then move both index and data to S3 in buckets of `S3_BLOCK_SIZE`. The .frm file is also copied to S3 for discovery to support discovery for other MariaDB servers. You can also use `ALTER TABLE` to change the structure of an S3 table.

Partitioning Tables

S3 tables can also be used with Partitioning tables. All ALTER PARTITION operations are supported except:

- `REBUILD PARTITION`
- `TRUNCATE PARTITION`
- `REORGANIZE PARTITION`

Big Reads

One of the properties of many S3 implementations is that they favor large reads. It's said that 4M gives the best performance, which is why the default value for `S3_BLOCK_SIZE` is 4M.

Compression

If compression (`COMPRESSION_ALGORITHM=zlib`) is used, then all index blocks and data blocks are compressed. The `.frm` file and Aria definition header (first page/pages in the index file) are not compressed as these are used by discovery/open.

If compression is used, then the local block size is `S3_BLOCK_SIZE`, but the block stored in S3 are the size of the compressed block.

Typical compression we have seen is in the range of 80% saved space.

Structure Stored on S3

The table are copied in S3 into the following locations:

```
frm file (for discovery):
s3_bucket/database/table/frm

First index block (contains description of the Aria file):
s3_bucket/database/table/aria

Rest of the index file:
s3_bucket/database/table/index/block_number

Data file:
s3_bucket/database/table/data/block_number
```

`block_number` is a 6-digit decimal number, prefixed with `0`. (It can be larger than 6 numbers – the prefix is just for nice output.)

Using the awsctl Python Tool to Examine Data

Installing awsctl on Linux

```
# install python-pip (on an OpenSuse distribution)
# use the appropriate command for your distribution
zypper install python-pip
pip install --upgrade pip

# the following installs awscli tools in ~/.local/bin
pip install --upgrade --user awscli
export PATH=~/.local/bin:$PATH

# configure your aws credentials
aws configure
```

Using the awsctl Tool

One can use the `aws` python tool to see how things are stored on S3:

```
shell> aws s3 ls --recursive s3://mariadb-bucket/
2019-05-10 17:46:48       8192 foo/test1/aria
2019-05-10 17:46:49    3227648 foo/test1/data/000001
2019-05-10 17:46:48        942 foo/test1/frm
2019-05-10 17:46:48    1015808 foo/test1/index/000001
```

To delete an obsolete table `foo.test1` one can do:

```
shell> ~/.local/bin/aws s3 rm --recursive s3://mariadb-bucket/foo/test1
delete: s3://mariadb-bucket/foo/test1/aria
delete: s3://mariadb-bucket/foo/test1/data/000001
delete: s3://mariadb-bucket/foo/test1/frm
delete: s3://mariadb-bucket/foo/test1/index/000001
```

Testing Connections to S3

> **Note:**
>
> The S3 storage engine is available from MariaDB 10.5.4.

If you can't get the S3 storage engine to work, here are some steps to help verify where the problem could be.

S3 Connection Variables

In most cases the problem is to correctly set the S3 connection variables.

Key S3 variables are:

- s3_access_key: The AWS access key to access your data
- s3_secret_key: The AWS secret key to access your data
- s3_bucket: The AWS bucket where your data should be stored. All MariaDB table data is stored in this bucket.
- s3_region: The AWS region where your data should be stored.
- s3_host_name: Hostname for the S3 service.
- s3_provider: Enable S3 provider specific compatibility tweaks. "Default", "Amazon", or "Huawei".

- s3_protocol_version: Protocol used to communicate with S3. One of “Amazon” or “Original”

There are several ways to ensure you get them right, detailed in the following sections.

Using aria_s3_copy to Test the Connection

aria_s3_copy is a tool that allows you to copy aria tables to and from S3. It’s useful for testing the connection as it allows you to specify all s3 options on the command line.

Execute the following sql commands to create a trivial sql table:

```
USE test;
CREATE TABLE s3_test (a INT) ENGINE=aria row_format=page transactional=0;
INSERT INTO s3_test VALUES (1),(2);
FLUSH TABLES s3_test;
```

Now you can use the aria_s3_copy tool to copy this to S3 from your shell/the command line:

```
shell> cd mariadb-data-directory/test
shell> aria_s3_copy --op=to --verbose --force --**other*options* s3_test.frm

Copying frm file s3_test.frm
Copying aria table: test.s3_test to s3
Creating aria table information test/s3_test/aria
Copying index information test/s3_test/index
Copying data information test/s3_test/data
```

As you can see from the above, aria_s3_copy is using the current directory as the database name.

You can also set the aria_s3_copy options in your my.cnf file to avoid some typing.

Using mariadb-test-run to Test the Connection and the S3 Storage Engine

One can use the MariaDB test system to run all default S3 test against your S3 storage.

To do that you have to locate the `mysql-test` directory in your system and `cd` to it.

The config file for the S3 test system can be found at `suite/s3/my.cnf`.
To enable testing you have to edit this file and add the s3 connection options to the end of the file. It should look something like this after editing:

```
!include include/default_mysqld.cnf
!include include/default_client.cnf

[mysqld.1]
s3=ON
#s3-host-name=s3.amazonaws.com
#s3-protocol-version=Amazon
s3-bucket=MariaDB
s3-access-key=
s3-secret-key=
s3-region=
```

You must give values for `s3-access-key`, `s3-secret-key` and `s3-region` that reflects your S3 provider. The `s3-bucket` name is defined by your administrator.

If you are not using Amazon Web Services as your S3 provider you must also specify `s3-hostname` and possibly change `s3-protocol-version` to “Original”.

Now you can test the configuration:

```
shell> cd **mysql-test** directory
shell> ./mysql-test-run --suite=s3
...
s3.no_s3                                 [ pass ]      5
s3.alter                                 [ pass ]  11073
s3.arguments                             [ pass ]   2667
s3.basic                                 [ pass ]   2757
s3.discovery                             [ pass ]   7851
s3.select                                [ pass ]   1325
s3.unsupported                           [ pass ]    363
```

Note that there may be more tests in your output as we are constantly adding more tests to S3 when needed.

Create a trace of the S3 connection to see what goes wrong

One can use the `s3_debug` variable to get a trace of the S3 engines interaction with the S3 storage. The trace is sent to the error log.

Here follows one example on can use to get a trace if `ALTER TABLE .. ENGINE=S3` fails:

```
USE test;
CREATE TABLE s3_test (a INT) ENGINE=aria row_format=page transactional=0;
INSERT INTO s3_test VALUES (1),(2);
SET @@global.s3_debug=1;
ALTER TABLE s3_test ENGINE=S3;
SET @@global.s3_debug=0;
```

If you have problems deciper the trace, you can always create a ticket on MariaDB Jira and explain the problem you have, including any errors. Don't forget to include the trace!

What to do when you have got things to work

When you got the connection to work, you should add the options to your global my.cnf file. Now you can start testing S3 from your mariadb command client by converting some existing table to S3 with ALTER TABLE … ENGINE=S3.

aria_s3_copy

> **Note:**
>
> The S3 storage engine is available from MariaDB 10.5.4.

`aria_s3_copy` is a tool for copying an Aria table to and from S3.

The Aria table must be non transactional and have ROW_FORMAT=PAGE.

For `aria_s3_copy` to work reliably, the table should not be changed by the MariaDB server during the copy, and one should have first performed FLUSH TABLES to ensure that the table is properly closed.

Example of properly created Aria table:

```
CREATE TABLE test1 (a INT) transactional=0 row_format=PAGE engine=aria;
```

> **Note:**
>
> ALTER TABLE table_name ENGINE=S3 works for any kind of table. It internally converts the table to an Aria table, then moves it to S3 storage.

Main Arguments

Option	Description
-?, –help	Display this help and exit.
-k, –s3-access-key=name	AWS access key ID
-r, –s3-region=name	AWS region
-K, –s3-secret-key=name	AWS secret access key ID
-b, –s3-bucket=name	AWS prefix for tables
-h, –s3-host-name=name	Host name to S3 provider
-c, –compress	Use compression
-o, –op=name	Operation to execute. One of ‘from_s3’, ‘to_s3’ or ‘delete_from_s3’
-d, –database=name	Database for copied table (second prefix). If not given, the directory of the table file is used
-B, –s3-block-size=#	Block size for data/index blocks in s3
-L, –s3-protocol-version=name	Protocol used to communication with S3. One of “Amazon” or “Original”.
-f, –force	Force copy even if target exists
-v, –verbose	Write more information
-V, –version	Print version and exit.
-#, –debug[=name]	Output debug log. Often this is ‘d:t:o,filename’.
–s3-debug	Output debug log from marias3 to stdout

-p, –s3-port=#	Port number to connect to (0 means use default)
-P, –s3-use-http	If true, force use of HTTP protocol

Typical Configuration in a my.cnf File

```
[aria_s3_copy]
s3-bucket=mariadb
s3-access-key=xxxx
s3-secret-key=xxx
s3-region=eu-north-1
#s3-host-name=s3.amazonaws.com
#s3-protocol-version=Amazon
verbose=1
op=to
```

Example Usage

The following code will copy an existing Aria table named `test1` to S3.
If the `--database` option is not given, then the directory name where the table files exist are used as the database.

```
shell> aria_s3_copy --force --op=to --database=foo --compress --verbose --s3_block_size=4M test1
Delete of aria table: foo.test1
Delete of index information foo/test1/index
Delete of data information foo/test1/data
Delete of base information and frm
Copying frm file test1.frm
Copying aria table: foo.test1 to s3
Creating aria table information foo/test1/aria
Copying index information foo/test1/index
.
Copying data information foo/test1/data
.
```

When using `--verbose`, `aria_s3_copy` will write a dot for each #/79 part of the file copied.

SphinxSE

> **Note:**
>
> SphinxSE is a community contribution to MariaDB Server, developed and maintained by the Sphinx developers. The Sphinx search daemon that it connects to is separate software, and isn't part of MariaDB Server.

See About SphinxSE.

SphinxSE is a storage engine that connects MariaDB to the Sphinx search daemon, enabling advanced full-text search capabilities within MariaDB.

See Installing Sphinx.

Instructions for installing the standalone Sphinx search server on various operating systems, a prerequisite for using the SphinxSE storage engine.

See Installing and Testing SphinxSE with MariaDB.

Learn how to install the SphinxSE plugin in MariaDB and run tests to verify the connection between the database and the Sphinx daemon.

See Configuring Sphinx.

A guide to configuring the Sphinx daemon (`searchd`) to index data from MariaDB, including setting up `sphinx.conf` and creating necessary users.

This page is licensed: CC BY-SA / Gnu FDL

About SphinxSE

The Sphinx storage engine (SphinxSE) is a storage engine that talks to `searchd` (the Sphinx daemon) to enable text searching. Sphinx and SphinxSE is used as a faster and more customizable alternative to MariaDB's built-in full-text search.

Sphinx does not depend on MariaDB, and can run independently, but SphinxSE provides a convenient interface to the underlying Sphinx daemon.

Enabling SphinxSE in MariaDB

The Sphinx storage engine is included in the source, binaries, and packages of MariaDB.

> **Note:**
>
> However, make sure the Sphinx daemon is installed on your system. Instructions for installing it are here.

SphinxSE is built as a dynamically loadable .so plugin. To use it, you need to perform a one-time install:

```
INSTALL SONAME 'ha_sphinx';
```

If you're getting a `Symbol not found` error, this is due to a server/plugin mismatch.

Once installed, SphinxSE will show up in the list of installed storage engines:

```
SHOW ENGINES;
+------------+---------+----------------------------------------------+--------------+------+------------+
| Engine     | Support | Comment                                      | Transactions | XA   | Savepoints |
+------------+---------+----------------------------------------------+--------------+------+------------+
...
| SPHINX     | YES     | Sphinx storage engine 0.9.9                  | NO           | NO   | NO         |
...
+------------+---------+----------------------------------------------+--------------+------+------------+
```

This is a one-time step and will not need to be performed again.

Note: SphinxSE is just the storage engine part of Sphinx. You will have to install Sphinx itself in order to make use of SphinxSE in MariaDB.

> **Note:**
>
> Despite the name, SphinxSE does not actually store any data itself. It is just a built-in client which allows MariaDB to talk to Sphinx, run search queries, and obtain search results. All indexing and searching happens outside MariaDB.

Some SphinxSE applications include:

- easier porting of MariaDB/MySQL FTS applications to Sphinx
- allowing Sphinx use with programming languages for which native APIs are not available yet
- optimizations when additional Sphinx result set processing on the MariaDB side is required (eg. JOINs with original document tables, additional
  MariaDB-side filtering, and etc…)

Using SphinxSE

Basic Usage

To search via SphinxSE, you would need to create a special `ENGINE=SPHINX` "search table", and then `SELECT` from it with full text query put into the `WHERE` clause for query column.

Here is an example create statement and search query:

```
CREATE TABLE t1
(
    id          BIGINT UNSIGNED NOT NULL,
    weight      INTEGER NOT NULL,
    query       VARCHAR(3072) NOT NULL,
    group_id    INTEGER,
    INDEX(query)
) ENGINE=SPHINX CONNECTION="sphinx://127.0.0.1:9312/test1";

SELECT * FROM t1 WHERE query='test it;mode=any';
```

The first three columns of the search table must have a type of `BIGINT` for the 1st column (document id), `INTEGER` or `BIGINT` for the 2nd column (match weight), and `VARCHAR` or `TEXT` for the 3rd column (your query), respectively. This mapping is fixed; you cannot omit any of these three required columns, or move them around, or change types. Also, the query column must be indexed; all the others must be kept unindexed. Column names are ignored so you can use arbitrary ones.

Additional columns must be either `INTEGER`, `TIMESTAMP`, `BIGINT`, `VARCHAR`, or `FLOAT`. They are bound to the attributes provided in the Sphinx result set by name, so their names must match the attribute names specified in `sphinx.conf`. If there's no such attribute name in the Sphinx search results, the additional columns will have `NULL` values.

Special "virtual" attribute names can also be bound to SphinxSE columns. `_sph_` needs to be used instead of `@` for that. For instance, to obtain the values of '`@groupby`', '`@count`', or '`@distinct`' virtual attributes, use '`_sph_groupby`', '`_sph_count`' or '`_sph_distinct`' column names, respectively.

The `CONNECTION` string parameter is used to specify the default `searchd` host, port, and indexes for queries issued using this table. If no connection string is specified in `CREATE TABLE`, index name '`*`' (ie. search all indexes) and '`127.0.0.1:9312`' are assumed. The connection string syntax is as follows:

```
CONNECTION="sphinx://HOST:PORT/INDEXNAME"
```

You can change the default connection string later like so:

```
ALTER TABLE t1 CONNECTION="sphinx://NEWHOST:NEWPORT/NEWINDEXNAME";
```

You can also override all these parameters per-query.

Note: To use Linux sockets you can modify the searchd section of the Sphinx configuration file, setting the listen parameter to a socket file. Instruct SphinxSE about the socket using CONNECTION="unix:*unix/domain/socket[:index]".*

Search Options

As seen in the example above, both query text and search options should be put into the '`WHERE`' clause of the search query column (i.e. the 3rd column); the options are separated by semicolons ('`;`') and separate names from values using an equals sign ('`=`'). Any number of options can be specified. Available options are:

- query - query text;
- mode - matching mode. Must be one of "all", "any", "phrase", "boolean", or "extended". Default is "all";
- sort - match sorting mode. Must be one of "relevance", "attr_desc", "attr_asc", "time_segments", or "extended". In all modes besides "relevance" attribute name (or sorting clause for "extended") is also required after a colon:

```
... WHERE query='test;sort=attr_asc:group_id';
... WHERE query='test;sort=extended:@weight desc, group_id asc';
```

- offset - offset into result set, default is 0;
- limit - amount of matches to retrieve from result set, default is 20;
- index - names of the indexes to search:

```
... WHERE query='test;index=test1;';
... WHERE query='test;index=test1,test2,test3;';
```

- minid, maxid - min and max document ID to match;
- weights - comma-separated list of weights to be assigned to Sphinx full-text fields:

```
... WHERE query='test;weights=1,2,3;';
```

- filter, !filter - comma-separated attribute name and a set of values to match:

```
# only include groups 1, 5 and 19
... WHERE query='test;filter=group_id,1,5,19;';

# exclude groups 3 and 11
... WHERE query='test;!filter=group_id,3,11;';
```

- range, !range - comma-separated attribute name, min and max value to match:

```
# include groups from 3 to 7, inclusive
... WHERE query='test;range=group_id,3,7;';

# exclude groups from 5 to 25
... WHERE query='test;!range=group_id,5,25;';
```

- maxmatches - per-query max matches value:

```
... WHERE query='test;maxmatches=2000;';
```

- groupby - group-by function and attribute:

```
... WHERE query='test;groupby=day:published_ts;';
... WHERE query='test;groupby=attr:group_id;';
```

- groupsort - group-by sorting clause:

```
... WHERE query='test;groupsort=@count desc;';
```

- indexweights - comma-separated list of index names and weights to use when searching through several indexes:

```
... WHERE query='test;indexweights=idx_exact,2,idx_stemmed,1;';
```

- comment - a string to mark this query in query log (mapping to $comment parameter in Query() API call):

```
... WHERE query='test;comment=marker001;';
```

- select - a string with expressions to compute (mapping to SetSelect() API call):

```
... WHERE query='test;select=2*a+3*b as myexpr;';
```

Note

It is much more efficient to allow Sphinx to perform sorting, filtering, and slicing of the result set than to raise max matches count and use '`WHERE`', '`ORDER BY`', and '`LIMIT`' clauses on the MariaDB side. This is for two reasons:

1. Sphinx does a number of optimizations and performs better than MariaDB/MySQL on these tasks.
2. Less data would need to be packed by `searchd`, and transferred and unpacked by SphinxSE.

SHOW ENGINE SPHINX STATUS

Starting with version 0.9.9-rc1, additional query info besides the result set can be retrieved with the '`SHOW ENGINE SPHINX STATUS`' statement:

```
SHOW ENGINE SPHINX STATUS;
+--------+-------+-----------------------------------------------+
| Type   | Name  | Status                                        |
+--------+-------+-----------------------------------------------+
| SPHINX | stats | total: 25, total found: 25, time: 126, words: 2 |
| SPHINX | words | sphinx:591:1256 soft:11076:15945              |
+--------+-------+-----------------------------------------------+
```

This information can also be accessed through status variables. Note that this method does not require super-user privileges.

```
SHOW STATUS LIKE 'sphinx_%';
+--------------------+---------------------------------+
| Variable_name      | Value                           |
+--------------------+---------------------------------+
| sphinx_total       | 25                              |
| sphinx_total_found | 25                              |
| sphinx_time        | 126                             |
| sphinx_word_count  | 2                               |
| sphinx_words       | sphinx:591:1256 soft:11076:15945 |
+--------------------+---------------------------------+
```

JOINs with SphinxSE

You can perform `JOIN`s on a SphinxSE search table and tables using other engines. Here's an example with "documents" from example.sql:

```
SELECT content, date_added FROM test.documents docs
    JOIN t1 ON (docs.id=t1.id)
    WHERE query="one document;mode=any";
+-----------------------------------+---------------------+
| content                           | docdate             |
+-----------------------------------+---------------------+
| this is my test document number two | 2006-06-17 14:04:28 |
| this is my test document number one | 2006-06-17 14:04:28 |
+-----------------------------------+---------------------+

SHOW ENGINE SPHINX STATUS;
+--------+-------+-----------------------------------------------+
| Type   | Name  | Status                                        |
+--------+-------+-----------------------------------------------+
| SPHINX | stats | total: 2, total found: 2, time: 0, words: 2 |
| SPHINX | words | one:1:2 document:2:2                          |
+--------+-------+-----------------------------------------------+
```

Building snippets (excerpts) via MariaDB

Starting with version 0.9.9-rc2, SphinxSE also includes a UDF function that lets you create snippets through MariaDB. The functionality is fully similar to the BuildExcerprts API call but is accessible through MariaDB+SphinxSE.

The function name must be '`sphinx_snippets`', you can not use an arbitrary name. Function arguments are as follows:

```
Prototype: function sphinx_snippets ( document, index, words, [options] );
```

Document and words arguments can be either strings or table columns. Options must be specified like this: `'value' AS option_name`. For a list of supported options, refer to the BuildExcerprts() API call. The only UDF-specific additional option is named 'sphinx' and lets you specify searchd location (host and port).

Usage examples:

```
SELECT sphinx_snippets('hello world doc', 'main', 'world',
    'sphinx://192.168.1.1/' AS sphinx, true AS exact_phrase,
    '[b]' AS before_match, '[/b]' AS after_match)
FROM documents;

SELECT title, sphinx_snippets(text, 'index', 'mysql php') AS text
    FROM sphinx, documents
    WHERE query='mysql php' AND sphinx.id=documents.id;
```

More Information

More information on Sphinx and SphinxSE is available on the Sphinx website.

Installing Sphinx

In order to use the Sphinx Storage Engine, it is necessary to install the Sphinx daemon.

Many Linux distributions have Sphinx in their repositories. These can be used to install Sphinx instead of following the instructions below, but these are usually quite old versions and don't all include API's for easy integration. Ubuntu users can use the updated repository at sphinxsearch-rel21 (see instructions below).

Debian and Ubuntu

Ubuntu users can make use of the repository, as follows:

```
sudo add-apt-repository ppa:builds/sphinxsearch-rel21
sudo apt-get update
sudo apt-get install sphinxsearch
```

Alternatively, install as follows:

- The Sphinx package and daemon are named `sphinxsearch`.
- `sudo apt-get install unixodbc libpq5 mariadb-client`
- `sudo dpkg -i sphinxsearch*.deb`
- Configure Sphinx as required
- You may need to check `/etc/default/sphinxsearch` to see that `START=yes`
- Start with `sudo service sphinxsearch start` (and stop with `sudo service sphinxsearch stop`)

Red Hat and CentOS

- The package name is `sphinx` and the daemon `searchd`.
- `sudo yum install postgresql-libs unixODBC`
- `sudo rpm -Uhv sphinx*.rpm`
- Configure Sphinx as required
- `service searchd start`

Windows

- Unzip and extract the downloaded zip file
- Move the extracted directory to `C:\Sphinx`
- Configure Sphinx as required
- Install as a service:
  - `C:\Sphinx\bin> C:\Sphinx\bin\searchd --install --config C:\Sphinx\sphinx.conf.in --servicename SphinxSearch`

Once Sphinx has been installed, it will need to be configured.

Full instructions, including details on compiling Sphinx yourself, are available at current.html.

This page is licensed: CC BY-SA / Gnu FDL

Installing and Testing SphinxSE with MariaDB

To use SphinxSE with MariaDB you need to first download and install Sphinx.

Complete Sphinx documentation is available on the Sphinx website.

Tips for Installing Sphinx

libexpat

One library we know you will need on Linux before you can install Sphinx is `libexpat`. If it is not installed, you will get the warning `checking for libexpat... not found`. On Suse Linux, the package is called `libexpat-devel`, on Ubuntu the package is called `libexpat1-dev`.

MariaDB detection

If you run into problems with MariaDB not being detected, use the following options:

```
--with-mysql            compile with MySQL support (default is enabled)
 --with-mysql-includes   path to MySQL header files
 --with-mysql-libs       path to MySQL libraries
```

The above will tell the `configure` script where your MySQL/MariaDB installation is.

Testing Sphinx

After installing Sphinx, you can check that things are working in MariaDB by doing the following:

```
cd installation-dir/mysql-test
./mysql-test-run --suite=sphinx
```

If the above test doesn't pass, check the logs in the `'var'` directory. If there is a problem with the sphinx installation, the reason can probably be found in the log file at `var/log/sphinx.sphinx/searchd/sphinx.log`.

This page is licensed: CC BY-SA / Gnu FDL

Configuring Sphinx

Before you can get Sphinx working with the Sphinx Storage Engine on MariaDB, you need to configure it.

- The default configuration file is called `sphinx.conf`, usually located in `/etc/sphinxsearch` (Debian/Ubuntu), `/etc/sphinx/sphinx.conf.` (Red Hat/CentOS) or `C:\Sphinx\sphinx.conf` (Windows).

If it doesn't already exist, you can use the sample configuration file, `sphinx.conf.dist`. There is also sample data supplied that we can use for testing. Load the sample data (which creates two tables, `documents` and `tags` in the `test` database), for example:

`mysql -u test < /usr/local/sphinx/etc/example.sql` (Red Hat, CentOS) `mysql -u test < /usr/share/doc/sphinxsearch/example-conf/example.sql` (Debian/Ubuntu)

The sample configuration file documents the available options. You will need to make at least a few changes. A MariaDB user with permission to access the database must be created:

```
CREATE USER 'sphinx'@localhost
  IDENTIFIED BY 'sphinx_password';
GRANT SELECT ON test.* TO 'sphinx'@localhost;
```

Add these details to the `mysql` section of the config file:

```
sql_host = localhost
sql_user = sphinx
sql_pass = sphinx_password
sql_db   = test
sql_port = 3306
```

On Windows, the `path` and `pid` lines will need to be changed to reflect a valid path, usually as follows:

```
path = C:\Sphinx\docsidx
...
pid_file = C:\Sphinx\sphinx.pid
```

The query in the configuration files is the query that are used for building the index. In the sample data, this is:

```
sql_query = \
  SELECT id, group_id, UNIX_TIMESTAMP(date_added) AS date_added, title, content \
  FROM documents
```

Spider

See Spider Storage Engine Overview.

An introduction to the Spider storage engine, which provides built-in sharding by linking to tables on remote MariaDB servers, supporting partitioning and XA transactions.

See Spider Storage Engine Introduction.

Explains the architecture of Spider, where a “Spider node” processes queries and distributes them to one or more “Data nodes” that actually store the data.

See Spider Differences Between SpiderForMySQL and MariaDB.

This page outlines the differences between the standalone SpiderForMySQL distribution and the version integrated into MariaDB Server, including version correspondence and feature availability.

See Spider Feature Matrix.

A matrix listing the features supported by Spider, including sharding, partitioning, XA transactions, and support for various SQL statements and functions.

See Spider Use Cases.

Describes common use cases for Spider, such as horizontal sharding for scalability, consolidating data from multiple sources, and migrating data between servers.

See Spider Installation.

A guide to installing the Spider storage engine on Debian/Ubuntu and other Linux distributions, including loading the plugin and configuring data nodes.

See Spider Cluster Management.

Covers advanced management topics like executing direct SQL on backends, copying tables between nodes, and monitoring the cluster using status variables.

See Spider Case Studies.

A list of real-world companies and projects using Spider for high-volume data handling, gaming, and analytics, illustrating its scalability.

See Spider Benchmarks.

Performance benchmark results for Spider, demonstrating its throughput and latency characteristics under various workloads compared to other configurations.

See Information Schema SPIDER_WRAPPER_PROTOCOLS Table.

Describes the SPIDER_WRAPPER_PROTOCOLS table, which lists the available foreign data wrappers (like `mysql`) that Spider can use to connect to remote servers.

See Spider Storage Engine Core Concepts.

Explains the fundamental concepts behind Spider, including its architecture as a proxy storage engine, sharding capabilities, and support for XA transactions across data nodes.

See Spider System Variables.

Comprehensive list of system variables to configure Spider globally or per session, affecting connection timeouts, buffering, and query pushdown strategies.

See Spider Table Parameters.

A reference for table-level parameters in Spider, which can be set via the COMMENT or CONNECTION string to control connection settings, monitoring, and query behavior.

See Spider Functions.

Explore Spider functions in MariaDB Server. Learn about the specialized functions that enhance data access and manipulation across sharded and distributed databases using the Spider storage engine.

See Spider FAQ.

Frequently asked questions about Spider, covering troubleshooting common errors, configuration best practices, and architectural questions regarding HA and sharding.

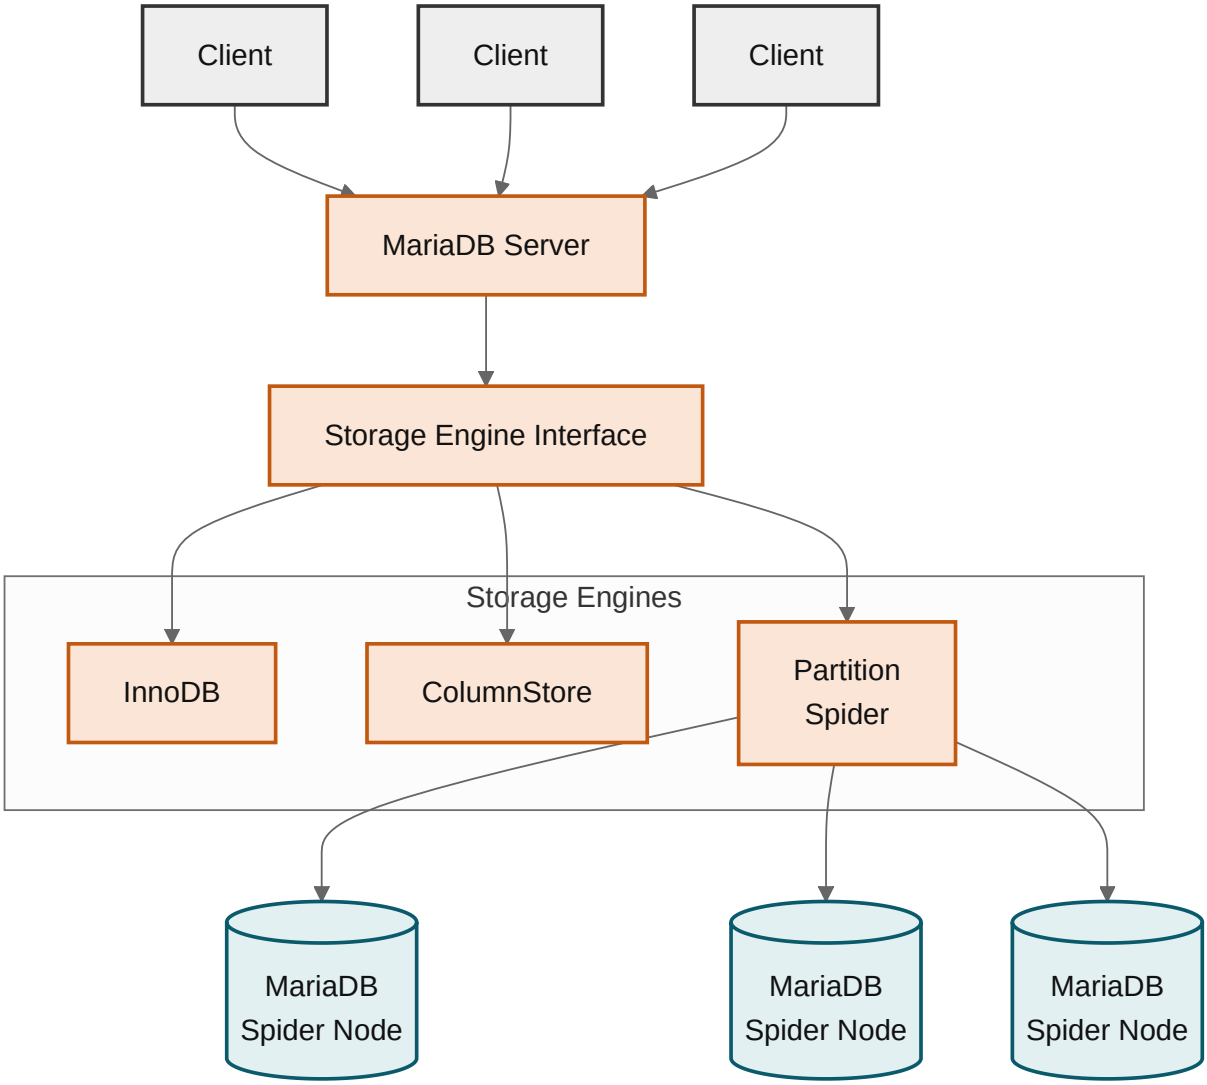
Spider Storage Engine Overview

About



The Spider storage engine sits alongside InnoDB and ColumnStore in the MariaDB Server's storage engine interface, and links out to multiple remote MariaDB Spider Node servers via Partition.

The Spider storage engine is a storage engine with built-in sharding features. It supports partitioning and xa transactions, and allows tables of different MariaDB instances to be handled as if they were on the same instance. It refers to one possible implementation of ISO/IEC 9075-9:2008 SQL/MED.

When a table is created with the Spider storage engine, the table links to the table on a remote server. The remote table can be of any storage engine. The table link is concretely achieved by the establishment of the connection from a local MariaDB server to a remote MariaDB server. The link is shared for all tables that are part of a the same transaction.

The Spider documentation on the MariaDB documentation is currently incomplete. See the Spider website for more:, as well as the spider-1.0-doc and spider-2.0-doc repositories.

Spider Versions in MariaDB

Spider Version	Introduced	Maturity
Spider 3.3.15	MariaDB 10.5.7, MariaDB 10.4.6	Stable

Spider Version	Introduced	Maturity
Spider 3.3.15	MariaDB 10.5.4	Gamma
Spider 3.3.14	MariaDB 10.4.3, MariaDB 10.3.13	Stable
Spider 3.3.13	MariaDB 10.3.7	Stable
Spider 3.3.13	MariaDB 10.3.3	Gamma
Spider 3.2.37	MariaDB 10.1.10, MariaDB 10.0.23	Gamma
Spider 3.2.21	MariaDB 10.1.5, MariaDB 10.0.18	Gamma
Spider 3.2.18	MariaDB 10.0.17	Gamma
Spider 3.2.11	MariaDB 10.0.14	Gamma
Spider 3.2.4	MariaDB 10.0.12	Gamma
Spider 3.2	MariaDB 10.0.11	Gamma
Spider 3.0	MariaDB 10.0.4	Beta

Usage

Basic Usage

To create a table in the Spider storage engine format, the COMMENT and/or CONNECTION clauses of the CREATE TABLE statement are used to pass connection information about the remote server.

For example, the following table exists on a remote server (in this example, the remote node was created with the MySQL Sandbox tool, an easy way to test with multiple installations)::

```
node1 >CREATE TABLE s(
  id INT NOT NULL AUTO_INCREMENT,
  code VARCHAR(10),
  PRIMARY KEY(id));
```

On the local server, a Spider table can be created as follows:

```
CREATE TABLE s(
  id INT NOT NULL AUTO_INCREMENT,
  code VARCHAR(10),
  PRIMARY KEY(id)
)
ENGINE=SPIDER
COMMENT='host "127.0.0.1", user "msandbox", password "msandbox", port "8607"';
```

Records can now be inserted on the local server, and they are stored on the remote server:

```
INSERT INTO s(code) VALUES ('a');

node1 > SELECT * FROM s;
+----+------+
| id | code |
+----+------+
|  1 | a    |
+----+------+
```

MariaDB starting with 10.8.1

Alternative to specifying the data node information in the COMMENT, certain information (server, database, table) can also be specified using Table Options, like so:

```
CREATE SERVER srv FOREIGN DATA WRAPPER mysql OPTIONS(
  HOST '127.0.0.1',
  USER 'msandbox',
  PASSWORD 'msandbox',
  PORT 8607);

CREATE TABLE s(
  id INT NOT NULL AUTO_INCREMENT,
  code VARCHAR(10),
  PRIMARY KEY(id)
)
ENGINE=SPIDER REMOTE_SERVER="srv" REMOTE_DATABASE="db" REMOTE_TABLE="s";
```

Further Examples

Preparing 10M record table using the sysbench utility

```
/usr/local/skysql/sysbench/bin/sysbench --test=oltp  --db-driver=mysql  --mysql-table-engine=innodb --
mysql-user=skysql --mysql-password=skyvodka --mysql-host=192.168.0.202 --mysql-port=5054 --oltp-table-
size=10000000  --mysql-db=test  prepare
```

Make a first read only benchmark to check the initial single node performance.

```
/usr/local/skysql/sysbench/bin/sysbench --test=oltp  --db-driver=mysql  --mysql-table-engine=innodb --
mysql-user=skysql --mysql-password=skyvodka --mysql-host=192.168.0.202 --mysql-port=5054 --mysql-db=test
--oltp-table-size=10000000 --num-threads=4 --max-requests=100000 --oltp-read-only=on run
```

```
sysbench 0.4.12:  multi-threaded system evaluation benchmark

Running the test with following options:
Number of threads: 4

Doing OLTP test.
Running mixed OLTP test
Doing read-only test
Using Special distribution (12 iterations,  1 pct of values are returned in 75 pct cases)
Using "BEGIN" for starting transactions
Using auto_inc on the id column
Maximum number of requests for OLTP test is limited to 100000
Threads started!
Done.

OLTP test statistics:
    queries performed:
        read:                            1400196
        write:                           0
        other:                           200028
        total:                           1600224
    transactions:                        100014 (1095.83 per sec.)
    deadlocks:                           0      (0.00 per sec.)
    read/write requests:                 1400196 (15341.58 per sec.)
    other operations:                    200028 (2191.65 per sec.)

Test execution summary:
    total time:                          91.2681s
    total number of events:              100014
    total time taken by event execution: 364.3693
    per-request statistics:
         min:                                  1.85ms
         avg:                                  3.64ms
         max:                                 30.70ms
         approx.  95 percentile:               4.66ms

Threads fairness:
    events (avg/stddev):           25003.5000/84.78
    execution time (avg/stddev):   91.0923/0.00
```

Define an easy way to access the nodes from the MariaDB or MySQL client.

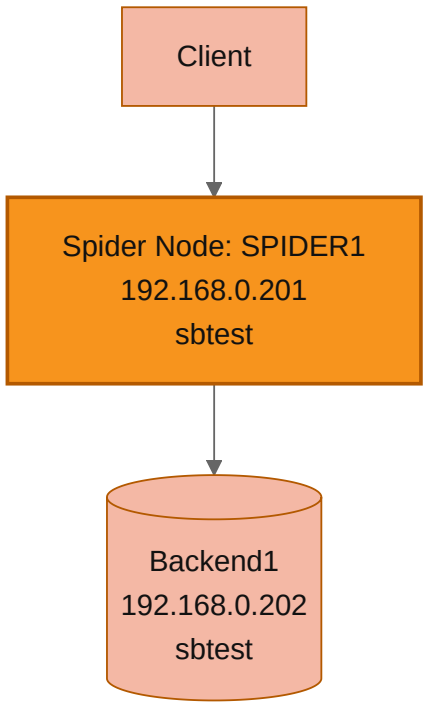
```
alias backend1='/usr/local/skysql/mysql-client/bin/mysql  --user=skysql --password=skyvodka --
host=192.168.0.202 --port=5054'
alias backend2='/usr/local/skysql/mysql-client/bin/mysql  --user=skysql --password=skyvodka --
host=192.168.0.203 --port=5054'
alias spider1='/usr/local/skysql/mysql-client/bin/mysql  --user=skysql --password=skyvodka --
host=192.168.0.201 --port=5054'
```

Create the empty tables to hold the data and repeat for all available backend nodes.

```
backend1 << EOF
CREATE DATABASE backend;
CREATE TABLE backend.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
EOF

backend2 << EOF
CREATE DATABASE backend;
CREATE TABLE backend.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
EOF
```

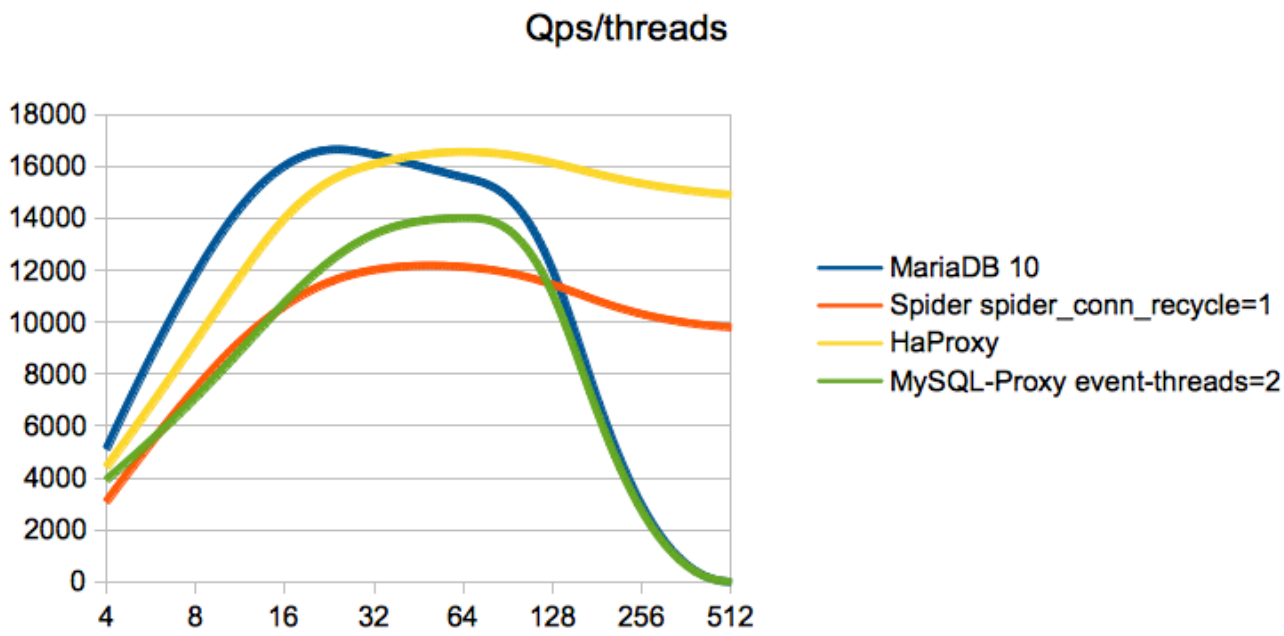
Federation Setup



A client talks to a single Spider node (SPIDER1), which federates the sbtest table to one remote backend server (BACKEND1).

```
spider1 << EOF
CREATE SERVER backend
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.202',
  DATABASE 'test',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);

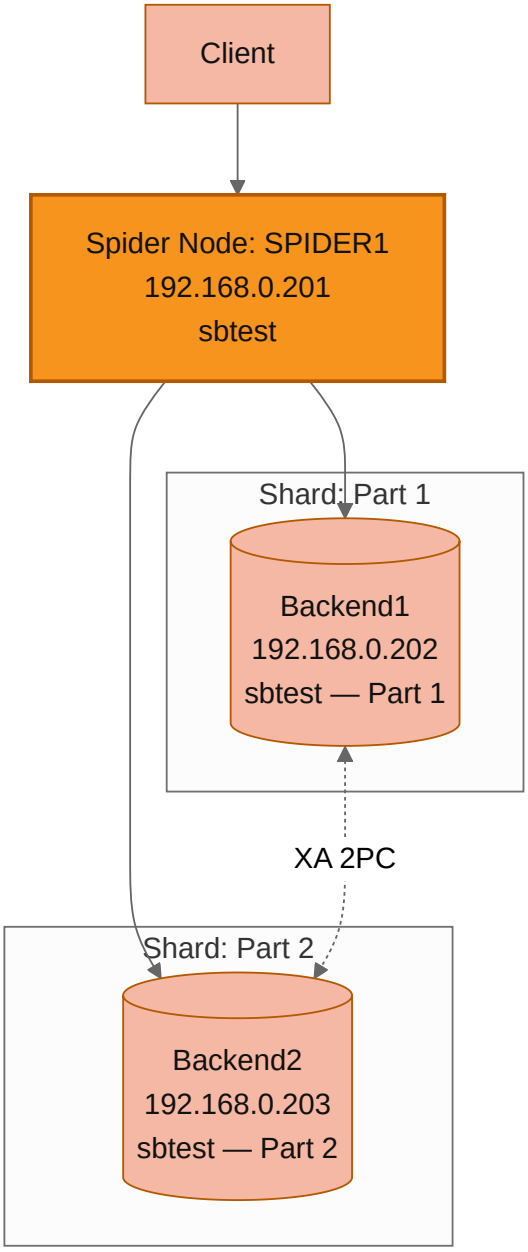
CREATE  TABLE test.sbtest
(
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=spider COMMENT='wrapper "mysql",srv "backend"';
SELECT * FROM test.sbtest LIMIT 10;
EOF
```



spbench10

Without connection pool or MariaDB thread pool, HaProxy and Spider have been protecting the tcp socket overflow without specific TCP tuning. In reality with a well tuned TCP stack or thread pool the curve should not decrease so abruptly to 0. Refer to the MariaDB Thread Pool to explore this feature.

Sharding Setup



A single Spider node (SPIDER1) shards sbtest across two backends, Backend1 (Part 1) and Backend2 (Part 2), coordinated by XA 2PC.

Create the spider table on the Spider Node

```
#spider1 << EOF
CREATE SERVER backend1
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.202',
  DATABASE 'backend',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);
CREATE SERVER backend2
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.203',
  DATABASE 'backend',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);
CREATE DATABASE IF NOT EXISTS backend;
CREATE  TABLE backend.sbtest
(
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1"',
 PARTITION pt2 COMMENT = 'srv "backend2"'
) ;
EOF
```

Copy the data from the original sysbench table to the spider table

```
#/usr/local/skysql/mariadb/bin/mysqldump  --user=skysql --password=skyvodka --host=192.168.0.202 --
port=5054 --no-create-info test sbtest | spider1 backend

#backend2 -e"SELECT count(*) FROM backend.sbtest;"
+----------+
| count(*) |
+----------+
|  3793316 |
+----------+
#backend1 -e"SELECT count(*) FROM backend.sbtest;"
+----------+
| count(*) |
+----------+
|  6206684 |
+----------+
```

We observe a common issue with partitioning is a non uniform distribution of data between the backends. based on the partition key hashing algorithm.

Rerun the Benchmark with less queries

```
#/usr/local/skysql/sysbench/bin/sysbench --test=oltp  --db-driver=mysql  --mysql-table-engine=innodb --
mysql-user=skysql --mysql-password=skyvodka --mysql-host=192.168.0.201 --mysql-port=5054 --mysql-
db=backend --mysql-engine-trx=yes --oltp-table-size=10000000 --num-threads=4 --max-requests=100 --oltp-
read-only=on run
```

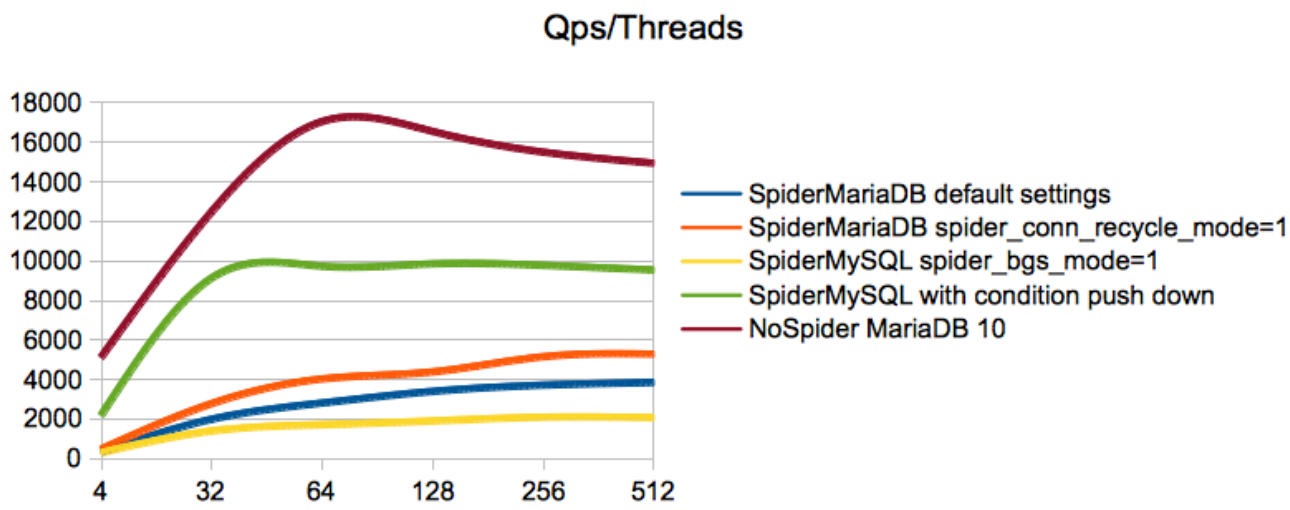
```
OLTP test statistics:
    queries performed:
        read:                            1414
        write:                           0
        other:                           202
        total:                           1616
    transactions:                        101    (22.95 per sec.)
    deadlocks:                           0      (0.00 per sec.)
    read/write requests:                 1414   (321.30 per sec.)
    other operations:                    202    (45.90 per sec.)

Test execution summary:
    total time:                          4.4009s
    total number of events:              101
    total time taken by event execution: 17.2960
    per-request statistics:
         min:                                  114.48ms
         avg:                                  171.25ms
         max:                                  200.98ms
         approx.  95 percentile:               195.12ms

Threads fairness:
    events (avg/stddev):           25.2500/0.43
    execution time (avg/stddev):   4.3240/0.04
```

The response time decreases to 0.04.
This is expected because the query latency is increased from multiple network round trips and condition push down is not implemented yet. Sysbench doing a lot of range queries. Just consider for now that this range query can be a badly optimized query.

We need to increase the concurrency to get better throughput.



spbench11

Background Setup

We have no background search available in MariaDB. It won't be available before MariaDB 10.2, but the next table definition mainly enables improving the performance of a single complex query plan with background search that can be found via the upstream spiral binaries MariaDB branch.

We have 4 cores per backend and 2 backends .

On `backend1`

```
#backend1 << EOF
CREATE DATABASE bsbackend1;
CREATE DATABASE bsbackend2;
CREATE DATABASE bsbackend3;
CREATE DATABASE bsbackend4;
CREATE TABLE bsbackend1.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend2.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend3.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend4.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
EOF
```

On `backend2`

```
#backend2 << EOF
CREATE DATABASE bsbackend5;
CREATE DATABASE bsbackend6;
CREATE DATABASE bsbackend7;
CREATE DATABASE bsbackend8;
CREATE TABLE bsbackend5.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend6.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend7.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
CREATE TABLE bsbackend8.sbtest (
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=InnoDB;
EOF
```

On `Spider Node`

```
#spider2 << EOF
CREATE SERVER bsbackend1 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.202', DATABASE
'bsbackend1',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend2 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.202', DATABASE
'bsbackend2',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend3 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.202', DATABASE
'bsbackend3',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend4 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.202', DATABASE
'bsbackend4',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend5 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.203', DATABASE
'bsbackend5',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend6 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.203', DATABASE
'bsbackend6',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend7 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.203', DATABASE
'bsbackend7',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);
CREATE SERVER bsbackend8 FOREIGN DATA WRAPPER mysql OPTIONS( HOST '192.168.0.203', DATABASE
'bsbackend8',USER 'skysql', PASSWORD 'skyvodka',PORT 5054);

CREATE DATABASE IF NOT EXISTS bsbackend;
CREATE  TABLE bsbackend.sbtest
(
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "bsbackend1"',
 PARTITION pt2 COMMENT = 'srv "bsbackend2"',
 PARTITION pt3 COMMENT = 'srv "bsbackend3"',
 PARTITION pt4 COMMENT = 'srv "bsbackend4"',
 PARTITION pt5 COMMENT = 'srv "bsbackend5"',
 PARTITION pt6 COMMENT = 'srv "bsbackend6"',
 PARTITION pt7 COMMENT = 'srv "bsbackend7"',
 PARTITION pt8 COMMENT = 'srv "bsbackend8"'
) ;
EOF
INSERT INTO  bsbackend.sbtest SELECT * FROM backend.sbtest;
```

Now test the following query :

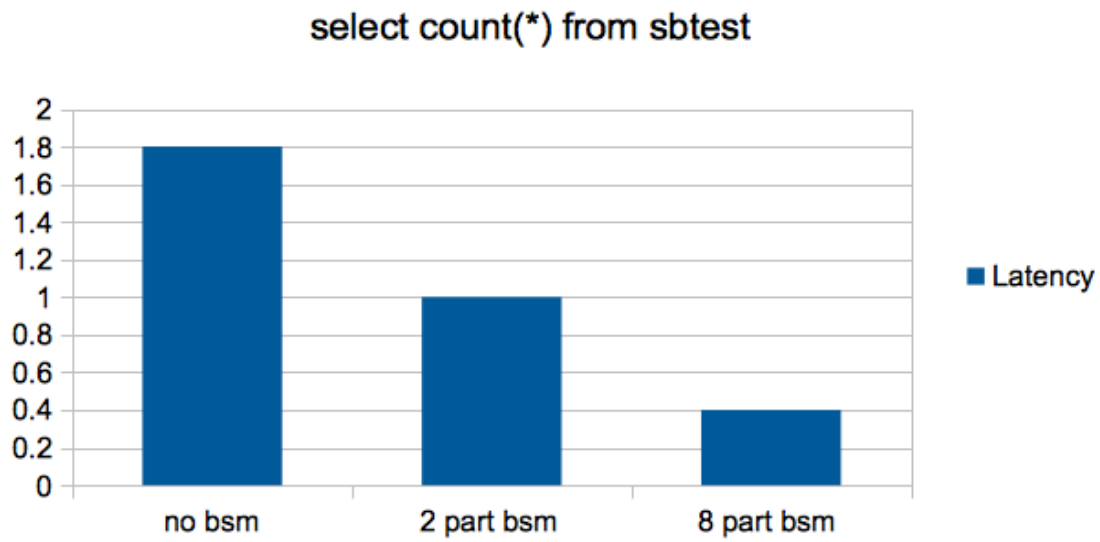
```
SELECT count(*) FROM sbtest;
+----------+
| count(*) |
+----------+
| 10000001 |
+----------+
1 row IN SET (8,38 sec)

SET spider_casual_read=1;
SET spider_bgs_mode=2;

SELECT count(*) FROM sbtest;
+----------+
| count(*) |
+----------+
| 10000001 |
+----------+
1 row IN SET (4,25 sec)

mysql> SELECT sum(k) FROM sbtest;
+--------+
| sum(k) |
+--------+
|      0 |
+--------+
1 row IN SET (5,67 sec)

mysql> SET spider_casual_read=0;
mysql> SELECT sum(k) FROM sbtest;
+--------+
| sum(k) |
+--------+
|      0 |
+--------+
1 row IN SET (12,56 sec)
```

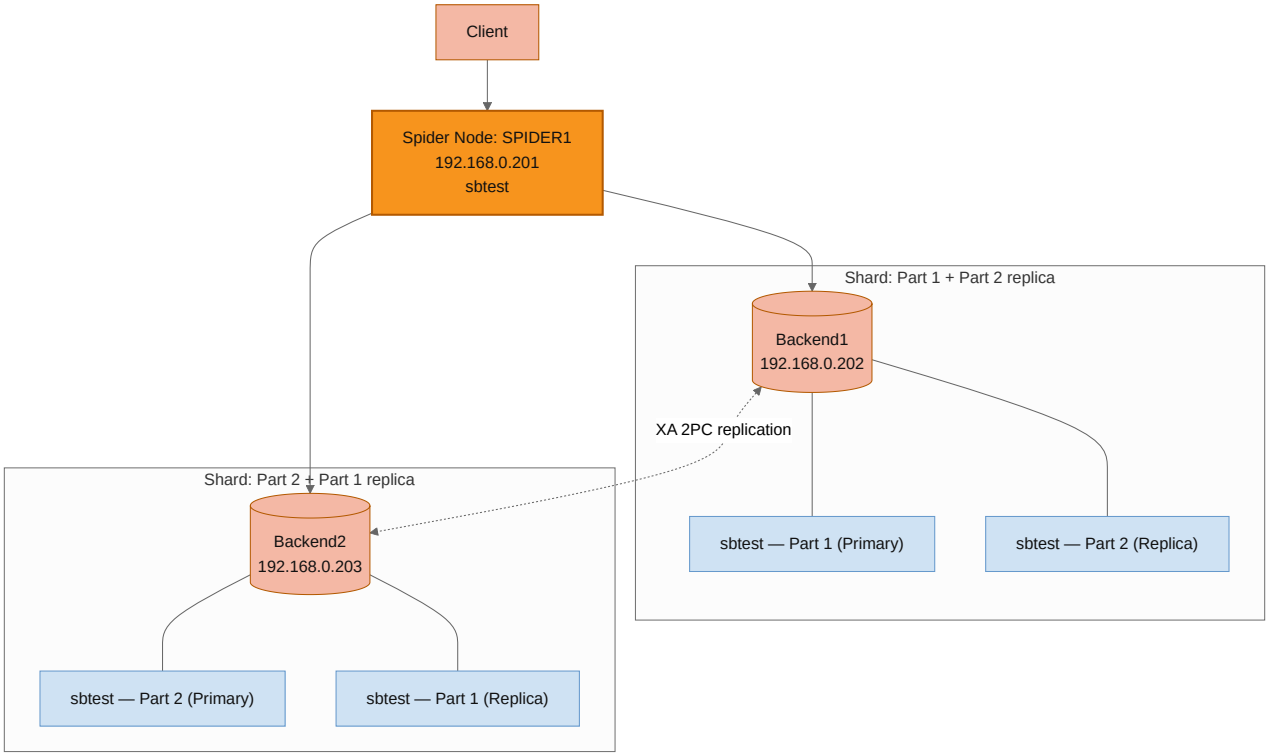


spbench8

High Availability Setup

MariaDB starting with 10.7.5

Spider's high availability feature has been deprecated (MDEV-28479), and are deleted. Please use other high availability solutions like replication or galera-cluster.



For high availability, Backend1 and Backend2 each hold their own primary shard plus a replica of the other's shard, kept in sync via XA 2PC.

```
#backend1 -e "CREATE DATABASE backend_rpl"
#backend2 -e "CREATE DATABASE backend_rpl"

#/usr/local/skysql/mariadb/bin/mysqldump  --user=skysql --password=skyvodka --host=192.168.0.202 --
port=5054  backend sbtest | backend1 backend_rpl
#/usr/local/skysql/mariadb/bin/mysqldump  --user=skysql --password=skyvodka --host=192.168.0.203 --
port=5054  backend sbtest | backend2 backend_rpl

#spider1 << EOF
DROP TABLE backend.sbtest;
CREATE SERVER backend1_rpl
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.202',
  DATABASE 'backend_rpl',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);
CREATE SERVER backend2_rpl
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.203',
  DATABASE 'backend_rpl',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);
CREATE  TABLE backend.sbtest
(
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1 backend2_rpl"',
 PARTITION pt2 COMMENT = 'srv "backend2 backend1_rpl"'
) ;
INSERT INTO backend.sbtest SELECT 10000001, 0, '' ,'replicas test';
EOF
#backend1 -e "SELECT * FROM backend.sbtest WHERE id=10000001";
+----------+---+---+---------------+
| id       | k | c | pad           |
+----------+---+---+---------------+
| 10000001 | 0 |   | replicas test |
+----------+---+---+---------------+
# backend2 -e "SELECT * FROM backend.sbtest WHERE id=10000001";
# backend2 -e "SELECT * FROM backend_rpl.sbtest WHERE id=10000001";
+----------+---+---+---------------+
| id       | k | c | pad           |
+----------+---+---+---------------+
| 10000001 | 0 |   | replicas test |
+----------+---+---+---------------+
```

What is happening if we stop one backend?

```
#spider1 -e "SELECT * FROM backend.sbtest WHERE id=10000001";
ERROR 1429 (HY000) at line 1: Unable to connect to foreign data source: backend1
```

Let’s fix this with spider monitoring. Note that msi is the list of spider nodes @@server_id variable participating in the quorum.

```
#spider1 << EOF
DROP  TABLE backend.sbtest;
CREATE  TABLE backend.sbtest
(
  id INT(10) UNSIGNED NOT NULL AUTO_INCREMENT,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT '',
  PRIMARY KEY (id),
  KEY k (k)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1 backend2_rpl",  mbk "2", mkd "2", msi "5054", link_status "0 0"',
 PARTITION pt2 COMMENT = 'srv "backend2 backend1_rpl",  mbk "2", mkd "2", msi "5054", link_status "0 0" '
) ;

CREATE SERVER mon
  FOREIGN DATA WRAPPER mysql
OPTIONS(
  HOST '192.168.0.201’,
  DATABASE 'backend',
  USER 'skysql',
  PASSWORD 'skyvodka',
  PORT 5054
);
INSERT INTO `mysql`.`spider_link_mon_servers` VALUES
('%','%','%',5054,'mon',NULL,NULL,NULL,NULL,NULL,NULL,NULL,NULL,NULL,NULL,0,NULL,NULL);
SELECT spider_flush_table_mon_cache();
EOF
```

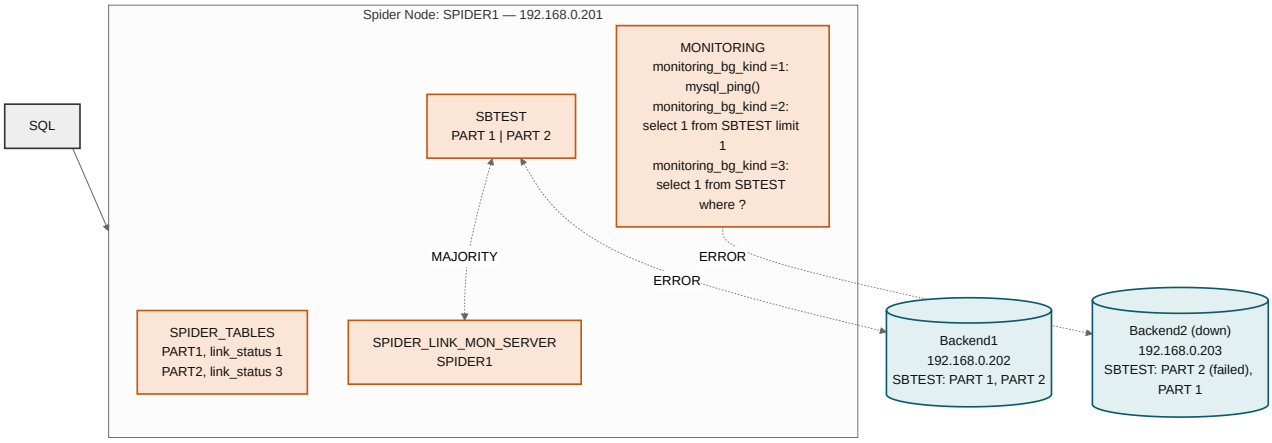
Monitoring should be setup between Spider nodes participating in the cluster. We only have one `Spider Node` and spider_link_mon_servers represent the inter-connection of all Spider nodes in our setup.

This simple setup does not bring HA in case the `Spider Node` is not available. In a production setup the number of `Spider Nodes` in the spider_link_mon_servers table should be at least 3 to get a majority consensus.

```
#spider1 -e "SELECT * FROM backend.sbtest WHERE id=10000001"
+----------+---+---+---------------+
| id       | k | c | pad           |
+----------+---+---+---------------+
| 10000001 | 0 |   | replicas test |
+----------+---+---+---------------+
```

Checking the state of the nodes:

```
#spider1 -e "SELECT db_name, table_name,server  FROM mysql.spider_tables WHERE link_status=3"
+---------+--------------+----------+
| db_name | table_name   | server   |
+---------+--------------+----------+
| backend | sbtest#P#pt1 | backend1 |
+---------+--------------+----------+
```



Spider's link monitoring: SPIDER1 tracks link_status for each partition, uses SPIDER_LINK_MON_SERVER and MAJORITY quorum voting to detect Backend1 vs. the failed Backend2, while a background MONITORING process pings and probes SBTEST on each backend.

No change has been made to cluster, so let's create a divergence:

```
# spider1 -e "INSERT INTO backend.sbtest SELECT 10000003, 0, '' ,'replicas test';"
# backend1 -e "SELECT * FROM backend.sbtest WHERE id=10000003"
# backend2 -e "SELECT * FROM backend_rpl.sbtest WHERE id=10000003"
+----------+---+---+---------------+
| id       | k | c | pad           |
+----------+---+---+---------------+
| 10000003 | 0 |   | replicas test |
+----------+---+---+---------------+
```

Reintroducing the failed backend1 in the cluster:

```
#spider1 << EOF
ALTER TABLE backend.sbtest
ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1 backend2_rpl"  mbk "2", mkd "2", msi "5054", link_status "2 0"',
 PARTITION pt2 COMMENT = 'srv "backend2 backend1_rpl"  mbk "2", mkd "2", msi "5054", link_status "0 2" '
) ;
SELECT spider_copy_tables('backend.sbtest#P#pt1','0','1');
SELECT spider_copy_tables('backend.sbtest#P#pt2','1','0');
ALTER TABLE backend.sbtest
ENGINE=spider COMMENT='wrapper "mysql", TABLE "sbtest"'
 PARTITION BY KEY (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1 backend2_rpl"  mbk "2", mkd "2", msi "5054", link_status "1 0"',
 PARTITION pt2 COMMENT = 'srv "backend2 backend1_rpl"  mbk "2", mkd "2", msi "5054", link_status "0 1" '
) ;
EOF
```

MariaDB Enterprise Spider Schema Design

Create Tables

Spider Tables can be created with MariaDB Enterprise Spider using the CREATE TABLE statement. The Enterprise Spider storage engine can be chosen for the table by specifying `ENGINE=Spider`.

For each Spider Table, MariaDB Enterprise Spider requires connection details for the Data Nodes. The connection details are provided by specifying Connection Options in the `COMMENT` option for the table or partition, depending on the topology.

Create Tables in a Federated Topology

In a Federated MariaDB Enterprise Spider topology, the Connection Options are specified in the `COMMENT` table option for the Spider Table:

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);

CREATE DATABASE spider_hq_sales;

CREATE TABLE spider_hq_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
COMMENT='server "hq_server", table "invoices"';
```

An alternative syntax is available. When you don't want to create a server object, the full connection details for the Data Node can be specified in the COMMENT table option:

```
CREATE TABLE spider_hq_sales.invoices_alternate (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
COMMENT='table "invoices", host "192.0.2.2", port "5801", user "spider_user", password "password",
database "hq_sales"';
```

Create Tables in a Sharded Topology

In a Sharded MariaDB Enterprise Spider topology, the Connection Options are specified in the `COMMENT` partition option for each partition of the Spider Table:

```
CREATE SERVER hq_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.2",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "hq_sales"
);

CREATE SERVER eastern_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.3",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "eastern_sales"
);

CREATE SERVER western_server
FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST "192.0.2.4",
   PORT 5801,
   USER "spider_user",
   PASSWORD "password",
   DATABASE "western_sales"
);

CREATE DATABASE spider_sharded_sales;

CREATE TABLE spider_sharded_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
PARTITION BY LIST(branch_id) (
   PARTITION hq_partition VALUES IN (1) COMMENT = 'server "hq_server", table "invoices"',
   PARTITION eastern_partition VALUES IN (2) COMMENT = 'server "eastern_server", table "invoices"',
   PARTITION western_partition VALUES IN (3) COMMENT = 'server "western_server", table "invoices"'
);
```

An alternative syntax is available. When you don’t want to create a server object, the full connection details for the Data Nodes can be specified in the COMMENT partition option:

```
CREATE TABLE spider_sharded_sales.invoices (
   branch_id INT NOT NULL,
   invoice_id INT NOT NULL,
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=Spider
PARTITION BY LIST(branch_id) (
   PARTITION hq_partition VALUES IN (1) COMMENT = 'table "invoices", host "192.0.2.2", port 5801, user
"spider_user", password "password", database "hq_sales"',
   PARTITION eastern_partition VALUES IN (2) COMMENT = 'table "invoices", host "192.0.2.3", port 5801,
user "spider_user", password "password", database "eastern_sales"',
   PARTITION western_partition VALUES IN (3) COMMENT = 'table "invoices", host "192.0.2.4", port 5801,
user "spider_user", password "password", database "western_sales"'
);
```

Connection Options

The following connection options are supported in the COMMENT table option for Federated Spider Tables and in the COMMENT partition option for Sharded Spider Tables:

Option	Data Type	Definition
database	String	The database to select when connecting to the Data Node.
host	String	The hostname or IP address for the Data Node. This option is mutually exclusive with socket.
password	String	The password to use when connecting to the Data Node.
port	Integer	The port to use when connecting to the Data Node. This option is mutually exclusive with socket.
socket	String	The path to the Unix socket file to use when connecting to the Data Node. This option is mutually exclusive with port.
ssl_ca	String	The path to the file with the TLS certificate authority chain.
ssl_capath	String	The path to the directory with the TLS certificate authority chain files.
ssl_cert	String	The path to the TLS client certificate.
ssl_key	String	The path to the TLS private key.
ssl_cipher	String	The path to the TLS certificate authority chain.
table	String	The table to query.
user	String	The username to use when connecting to the Data Node.
wrapper	String	The foreign data wrapper should be mariadb for the Federated and Sharded topologies or odbc for the ODBC topology.

Spider Federated Overview

Overview

Choose an operation for the Sharded MariaDB Enterprise Spider topology:

Operation	Description
Backup and Restore	How to create a new backup or restore an existing backup.
Migrate Tables	How to update the character set or collation.
Update Character Set or Collation	How to update the character set or collation.
Update Connection Options	How to update the connection options for a Data Node.

Update Character Sets and Collations

The character set or collation for the Spider Table can be updated or modified using the ALTER TABLE statement.

On the Spider Node, alter the Spider Table's character set and collation:

```
ALTER TABLE spider_hq_sales.invoices
   DEFAULT CHARACTER SET 'utf8mb4'
   DEFAULT COLLATE 'utf8mb4_general_ci';
```

If the new character set and collation are not compatible with the character set and collation used by the Data Table, you must also alter the character set and collation for the Data Table on the Data Node.

Update Connection Options

In a Federated MariaDB Enterprise Spider topology, the connection options for a Data Node can be updated using the ALTER TABLE statement.

- On the Spider Node*, alter the table's connection details:

```
ALTER TABLE spider_hq_sales.invoices
   COMMENT = 'server "new_hq_server", table "invoices"'
```

Federated MariaDB Enterprise Spider Topology Backup and Restore

Overview

When using Spider in the Federated MariaDB Enterprise Spider topology, backup and restore operations can be performed using MariaDB Backup or MariaDB Dump. These operations must be performed on the Spider Node and the Data Node.

MariaDB Backup

MariaDB Backup can be used to perform backup operations on Spider deployments.

Backup Spider with MariaDB Backup

MariaDB Backup can be used to create a physical backup of a Federated MariaDB Enterprise Spider topology. MariaDB Backup must be used to backup the Spider Node and the Data Node. The Spider Node and Data Node must be locked to guarantee that the backups of the Spider Node and Data Node are consistent.

The backup of the Spider Node contains:

- Physical backup for Spider Tables
- Physical backup for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Physical backup for any other database objects on the Spider Node

The backup of the Data Node contains:

- Physical backup for Data Tables
- Physical backup for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Physical backup for any other database objects on the Data Node

The following procedure shows how to take a consistent backup of a Spider Node and a Data Node deployed in a Spider Federated MariaDB Enterprise Spider topology.

1. On the Spider Node and on the Data Node, create a user account to perform the backup using the CREATE USER and GRANT statements:

```
CREATE USER 'mariadb-backup'@'localhost'
   IDENTIFIED BY 'mb_passwd';

GRANT RELOAD, PROCESS, LOCK TABLES, BINLOG MONITOR
   ON *.*
   TO 'mariadb-backup'@'localhost';
```

2. On the Data Node, grant the user account Spider uses to operate on the Data Node sufficient privileges to lock the Data Tables using the GRANT statement.

For example, on the hq_server Data Node:

```
GRANT LOCK TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.2';
```

3. On the Spider Node, acquire a read lock on Spider Tables using the LOCK TABLES statement:

```
LOCK TABLES spider_federated_sales.invoices READ;
```

Keep this session open during the rest of the procedure.

The read lock will propagate to the Data Tables on the Data Node. The read locks will prevent the Data Tables from changing during the backup, so the backups of the Spider Node and the Data Node are consistent.

4. On the Data Node, perform the backup using MariaDB Backup:

```
$ sudo mariadb-backup --backup \
   --target-dir=/data/backups/full \
   --user=mariadb-backup \
   --password='mb_passwd'
```

5. When the Data Node backup is complete, perform the backup on the Spider Node using MariaDB Backup:

```
$ sudo mariadb-backup --backup \
   --target-dir=/data/backups/full \
   --user=mariadb-backup \
   --password='mb_passwd'
```

6. When the Spider Node backup is complete, release the table locks in your original session using the UNLOCK TABLES statement:

```
UNLOCK TABLES;
```

7. On the Spider Node and the Data Node, prepare each of the backups using MariaDB Backup:

```
$ sudo mariadb-backup --prepare \
   --target-dir=/data/backups/full
```

The Spider Node and the Data Node now have a complete backup of the data directory. Backups should be tested to confirm they are complete and consistent.

Restoring Spider with MariaDB Backup

MariaDB Backup can restore a Federated MariaDB Enterprise Spider topology from a backup taken with MariaDB Backup.

1. On the Spider Node and on the Data Node, stop the MariaDB Server process:

```
$ sudo systemctl stop mariadb
```

2. On the Spider Node and on the Data Node, empty the data directory:

```
$ sudo rm -fr /var/lib/mysql/*
```

3. On the Spider Node and on the Data Node, restore the backup for that server using MariaDB Backup:

```
$ sudo mariadb-backup --copy-back \
   --target-dir=/data/backups/full
```

4. On the Spider Node and on the Data Node, confirm that the restored files are owned by the user that owns the MariaDB Server process:

```
$ sudo chown -R mysql:mysql /var/lib/mysql
```

5. On the Spider Node and on the Data Node, start the MariaDB Server process:

```
$ sudo systemctl start mariadb
```

6. On the Spider Node, query a Spider Table to test it:

```
SELECT * FROM spider_hq_sales.invoices;
```

```
+-----------+------------+-------------+---------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date              | invoice_total | payment_method |
+-----------+------------+-------------+---------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
+-----------+------------+-------------+---------------------------+---------------+----------------+
```

MariaDB Dump

MariaDB Dump generates backup files containing the SQL statements necessary to recreate the database. MariaDB Dump is included with MariaDB Enterprise Server and can be used to backup databases in Spider deployments. The MariaDB Client can then be used to restore databases from a MariaDB Dump backup.

Backing Up Spider with MariaDB Dump

MariaDB Dump can be used to create a logical backup of a Federated MariaDB Enterprise Spider topology. MariaDB Dump must be used to backup the Spider Node and the Data Node. The Spider Node and Data Node must be locked to guarantee that the backups of the Spider Node and Data Node are consistent.

The backup of the Spider Node contains:

- Table definitions for Spider Tables
- Table definitions for all tables
- Table data for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Definitions for any other user accounts, privileges, views, and triggers on the Spider Node

The backup of the Data Node contains:

- Table definitions for Data Tables
- Table definitions for all tables
- Table data for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Definitions for any other user accounts, privileges, views, and triggers on the Data Node

The following procedure shows how to take a consistent backup of a Spider Node and a Data Node deployed in a Federated MariaDB Enterprise Spider topology.

1. On the Spider Node and on the Data Node, create a user account to perform the backup using the CREATE USER and GRANT statements:

```
CREATE USER 'mariadb-dump'@'localhost'
   IDENTIFIED BY 'md_passwd';

GRANT SELECT, INSERT, SHOW VIEW, TRIGGER, CREATE, ALTER, EVENT, RELOAD, LOCK TABLES
   ON *.*
   TO 'mariadb-dump'@'localhost';
```

2. On the Data Node, grant the user account Spider uses to operate on the Data Node sufficient privileges to lock the Data Tables using the GRANT statement.

For example, on the hq_server Data Node:

```
GRANT LOCK TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.2';
```

3. On the Spider Node, acquire a read lock on Spider Tables using the LOCK TABLES statement:

```
LOCK TABLES spider_federated_sales.invoices READ;
```

Keep this session open during the rest of the procedure.

The read lock will propagate to the Data Tables on the Data Node. The read locks will prevent the Data Tables from receiving any changes during the backup, which ensures the backups of the Spider Node and the Data Node are consistent.

4. On the Data Node, perform the backup using MariaDB Dump:

```
$ mariadb-dump \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --all-databases \
   --single-transaction \
   --default-character-set=utf8mb4 \
   > mariadb_dump.sql
```

5. When the Data Node has been backed up, perform the backup on the Spider Node using MariaDB Dump:

```
$ mariadb-dump \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --all-databases \
   --single-transaction \
   --default-character-set=utf8mb4 \
   > mariadb_dump.sql
```

6. When the Spider Node backup is complete, release the table locks in your original session using the UNLOCK TABLES statement:

```
UNLOCK TABLES;
```

The Spider Node and the Data Node now each have a mariadb_dump.sql backup file. This backup file contains the SQL statements needed to recreate the schema on the Spider Node and the schema and data on the Data Node. Backups should be tested to confirm they are complete and consistent.

Restoring Spider from MariaDB Dump

MariaDB Client can restore a Federated MariaDB Enterprise Spider topology from a backup taken with MariaDB Dump backup.

1. Stop all traffic to the Spider Node and the Data Node.
2. On the Spider Node, restore the backup for that server using MariaDB Client:

```
$ mariadb \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --default-character-set=utf8mb4 \
   < mariadb_dump.sql
```

3. On the Data Node, restore the backup for that server using MariaDB Client:

```
$ mariadb \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --default-character-set=utf8mb4 \
   < mariadb_dump.sql
```

On the Spider Node, query a Spider Table to test it:

```
SELECT * FROM spider_hq_sales.invoices;
```

```
+-----------+------------+-------------+----------------------------+--------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date               | invoice_total | payment_method |
+-----------+------------+-------------+----------------------------+--------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
+-----------+------------+-------------+----------------------------+--------------+----------------+
```

Federated MariaDB Enterprise Spider Topology Migrate Tables

Overview

The Federated MariaDB Enterprise Spider topology can be used to migrate tables from one MariaDB Enterprise Server node to another MariaDB Enterprise Server node:

- The MariaDB Enterprise Server node with the source table is configured as a Data Node.
- The MariaDB Enterprise Server node with the destination table is configured as a Spider Node.
- The Data Table is the source table on the Data Node.
- A Spider Table is created on the Spider Node that references the Data Table on the Data Node.
- On the Spider node, the Data Table's data is migrated to the destination table by querying the Spider Table like the following:

```
INSERT INTO innodb_tab
   SELECT * FROM spider_tab;
```

Follow the steps below to migrate tables using the Federated MariaDB Enterprise Spider topology.

Deploy the Federated Topology

Before you can migrate tables, the Federated MariaDB Enterprise Spider topology must be deployed.

For additional information, see "Deploy MariaDB Enterprise Spider".

Create Local Tables

A local copy of the table must be created. This new table will contain the migrated data.

- On the Spider Node*, create a local copy of each table that is being migrated:

```
CREATE DATABASE hq_sales;

CREATE SEQUENCE hq_sales.invoice_seq;

CREATE TABLE hq_sales.invoices (
   branch_id INT NOT NULL DEFAULT (1) CHECK (branch_id=1),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR migrated_hq_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;
```

Migrate the Tables

The table data can be migrated to the local table using the Spider Tables.

- On the Spider Node*, migrate the table data to the local copy of the table using the INSERT SELECT statement:

```
INSERT INTO hq_sales.invoices
   SELECT * FROM spider_hq_sales.invoices;
```

Test Read Operations

On the Spider Node, read from the local copy of the table using a SELECT statement to confirm that the data has been migrated:

```
SELECT * FROM hq_sales.invoices;
```

```
+-----------+------------+-------------+----------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date               | invoice_total | payment_method |
+-----------+------------+-------------+----------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
+-----------+------------+-------------+----------------------------+---------------+----------------+
```

ODBC MariaDB Enterprise Spider Topology Operations

See Use Spider ODBC to Connect to Oracle.

This guide details how to configure Spider to connect to an Oracle database via ODBC, enabling data migration and federated access to Oracle tables.

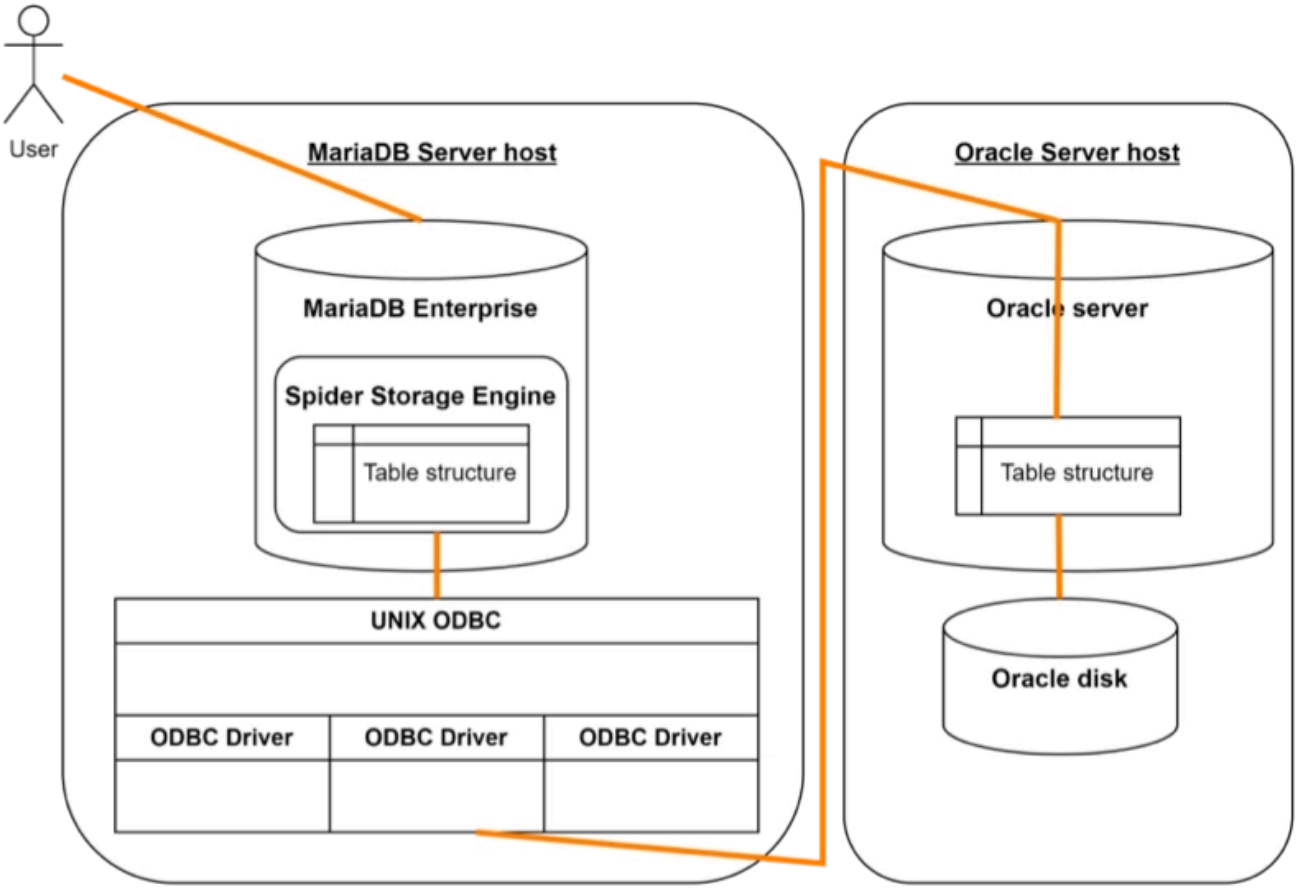
This page is: Copyright © 2026 MariaDB. All rights reserved.

Use Spider ODBC to Connect to Oracle

Overview

This article describes how to use Spider ODBC to connect to Oracle. This can make it easier to migrate, by not requiring a wholesale cutover, but instead enabling a piecemeal approach.

The setup looks as shown in this figure:



Prerequisites

In MariaDB,

- The Spider storage engine must be installed.
- The Spider storage engine plugin must be installed in MariaDB Enterprise Server. This is described in the instructions below.
- An ODBC driver manager, unixODBC, must be installed.

In Oracle Database,

- The ODBC driver must be installed.
- The Oracle Basic Client must be installed. This is a prerequisite for installing the ODBC driver.

> **Note:**
>
> The following procedure has been tested on *CentOS 7 AWS EC2 t3a.Medium* and a *t3.small RDS* Oracle 19 database. It assumes you are just doing a simple install of MariaDB. Also, the following schema is used to populate the Oracle database: Oracle Sample Database.

Instructions

> **Step 1**
>
> In your working directory, create a folder to hold the Oracle ODBC `RPMs mkdir oracle_odbc_rpms`, then change to that directory.

Step 2

Download the following files (make sure to use the appropriate driver for your scenario):

```
wget https://download.oracle.com/otn_software/linux/instantclient/1916000/oracle-instantclient19.16-odbc-19.16.0.0.0-1.x86_64.rpm
wget https://download.oracle.com/otn_software/linux/instantclient/1916000/oracle-instantclient19.16-sqlplus-19.16.0.0.0-1.x86_64.rpm
wget https://download.oracle.com/otn_software/linux/instantclient/1916000/oracle-instantclient19.16-basic-19.16.0.0.0-1.x86_64.rpm
```

Step 3

Install the RPMs:

```
yum localinstall *.rpm
```

Step 4

Add the following to `/etc/odbcinst.ini`:

```
[oracle]
Description = Oracle ODBC Connection
Driver = /usr/lib/oracle/19.16/client64/lib/libsqora.so.19.1
```

The driver path may be different if you downloaded a different version of the Oracle driver, be sure to update it with correct path for your scenario.

Step 5

Add the following to `/etc/odbc.ini`:

```
[ORARDS]
Description = Oracle
Driver = oracle
ServerName = REMOTE
UserID = {user_name}
Password = {password}
TNSNamesFile = /etc/tnsnames.ora
```

- `Driver` is the driver name in the `/etc/odbcinst.ini` .
- `Description` can be whatever you like, just make sure you use the same value later.
- `ServerName` is the TNSName given for our Oracle connection.
- Be sure to populate your user name and password.

Step 6

Add the following line to `/etc/tnsnames.ora`:

```
REMOTE=(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST={host_name/ip address})(PORT=1521))(CONNECT_DATA=(SERVICE_NAME={service_name})))
```

- Name the connection string as you like — just be sure to use the same name in the `odbc.ini` file.
- Make sure to include your hostname and IP address, and the service name for your instance.

Step 7

Verify that the ODBC connection is working with:

```
isql -v ORARDS
```

- `ORARDS` is the section name we gave our entry in `odbc.ini`. If you are using something different, replace `ORARDS` with whatever you use.
- If any errors come up, double-check the values entered into the `.ini` files.

Step 8

Start the MariaDB database:

```
systemctl start mariadb or systemctl start mysqld
```

Step 9

Log in to MariaDB, and run the following:

```
INSTALL SONAME 'ha_spider';
CREATE DATABASE spider_test;
USE spider_test;
CREATE OR REPLACE TABLE spider_test.contacts
(
  CONTACT_ID BIGINT NOT NULL PRIMARY KEY,
  FIRST_NAME  VARCHAR( 255 ) NOT NULL,
  LAST_NAME   VARCHAR( 255 ) NOT NULL,
  EMAIL       VARCHAR( 255 ) NOT NULL,
  PHONE       VARCHAR( 20 )          ,
  CUSTOMER_ID BIGINT) ENGINE=SPIDER
  CONNECTION='WRAPPER "odbc", DSN "ORARDS", table "CONTACTS"';
```

- This creates a new database and a table that should be able to connect to an Oracle server via ODBC.
- `DSN` must be the same put in the `odbc.ini file` .
- It's best to always use upper case for both column names and the table value in the comment section, because these values are passed directly to Oracle Database, which prefers upper-case object names.

Step 10

You should now be able to select data from `spider_test.contacts` table. That data is coming from the remote Oracle database.

Notes

- Spider ODBC to Oracle tables does not support `INSERT SELECT` statements, where the Spider table is the source of the data. (MENT-1588).
- If the version of MariaDB does not have the spider_direct_aggregate variable, you aren't able to use a few aggregate functions on their own. (MENT-1558).
- If you get the following error message: `Error from ODBC 0 01004 [Oracle][ODBC]String data, right truncated.`, you need to set a larger value for the variable spider_buffer_size. (MENT-1557).

Spider Sharded Overview

Overview

Choose an operation for the Sharded MariaDB Enterprise Spider topology:

Operation	Description
Add a Shard	How to add a new shard to a Spider Table.
Backup and Restore	How to create a new backup or restore an existing backup.
Update Character Set or Collation	How to update the character set or collation for a Spider Table.
Update Connection Options	How to update the connection options for a Data Node.

Update Character Sets and Collations

The character set or collation for the Spider Table can be updated or modified using the ALTER TABLE statement.

On the Spider Node, alter the Spider Table's character set and collation:

```
ALTER TABLE spider_sharded_sales.invoices
   DEFAULT CHARACTER SET 'utf8mb4'
   DEFAULT COLLATE 'utf8mb4_general_ci';
```

If the new character set and collation are not compatible with the character set and collation used by the Data Table, you must also alter the character set and collation for the Data Table on the Data Node.

Update Connection Options

In a Sharded MariaDB Enterprise Spider topology, the connection options for a Data Node can be updated using the ALTER TABLE statement.

On the Spider Node, alter the partition's connection details:

```
ALTER TABLE spider_sharded_sales.invoices
   REORGANIZE PARTITION hq_partition INTO (
      PARTITION hq_partition VALUES IN (1) COMMENT = 'server "new_hq_server", table "invoices"'
   );
```

Sharded MariaDB Enterprise Spider Topology Add a Shard

Overview

In a Sharded MariaDB Enterprise Spider topology, new shards can be added using the following procedure.

Create Spider User

Each data node requires a user account that the Spider Node uses to connect.

On the Data Node hosting the new shard, create the Spider user account for the Spider Node using the CREATE USER statement:

```
CREATE USER spider_user@192.0.2.1 IDENTIFIED BY "password";
```

Privileges are granted to the user account in a later step.

Test Spider User

On the Spider Node, confirm that the Spider user account can connect to the Data Node using MariaDB Client:

```
$ mariadb --user spider_user --host 192.0.2.2 --password
```

Configure Connection Details

The Spider Node requires connection details for each Data Node.

On the Spider Node, create a server object to configure the connection details for the Data Node hosting the new shard using the CREATE SERVER statement:

```
CREATE SERVER southern_server
   FOREIGN DATA WRAPPER mariadb
OPTIONS (
   HOST '192.0.2.6',
   PORT 5004,
   USER 'spider_user',
   PASSWORD 'password',
   DATABASE 'southern_sales'
);
```

The Data Node runs MariaDB Enterprise Server, so the `FOREIGN DATA WRAPPER` is set to mariadb.

Using a server object for connection details is optional. Alternatively, the connection details for the Data Node can be specified in the `COMMENT` table option of the CREATE TABLE statement when creating the Spider Table.

Create the Data Table

When queries read and write to a Spider Table, Spider reads and writes to the Data Tables for each partition on the Data Nodes. The Data Tables must be created on the Data Nodes with the same structure as the Spider Table.

If your Data Tables already exist, grant privileges on the tables to the Spider user.

On the Data Node hosting the new shard, create the Data Tables:

```
CREATE DATABASE southern_sales;

CREATE SEQUENCE southern_sales.invoice_seq;

CREATE TABLE southern_sales.invoices (
   branch_id INT NOT NULL DEFAULT (4) CHECK (branch_id=4),
   invoice_id INT NOT NULL DEFAULT (NEXT VALUE FOR hq_sales.invoice_seq),
   customer_id INT,
   invoice_date DATETIME(6),
   invoice_total DECIMAL(13, 2),
   payment_method ENUM('NONE', 'CASH', 'WIRE_TRANSFER', 'CREDIT_CARD', 'GIFT_CARD'),
   PRIMARY KEY(branch_id, invoice_id)
) ENGINE=InnoDB;

INSERT INTO southern_sales.invoices
   (customer_id, invoice_date, invoice_total, payment_method)
VALUES
   (1, '2020-05-25 10:22:11', 2083.56, 'CREDIT_CARD'),
   (2, '2020-05-25 11:42:33', 515.22, 'WIRE_TRANSFER'),
   (3, '2020-05-25 13:15:16', 1213.80, 'CASH');
```

The Spider Node reads and writes to the Data Table using the server and user account configured previously. The user account must have privileges on the table.

Grant Privileges

The Spider Node connects to the Data Nodes with the user account configured previously.

On the Data Node hosting the new shard, grant the Spider user sufficient privileges to operate on the Data Table:

```
GRANT ALL PRIVILEGES ON southern_sales.invoices TO 'spider_user'@'192.0.2.1';
```

Privileges for Spider BKA Mode

By default, the Spider user also requires the CREATE TEMPORARY TABLES privilege on the database containing the Data Table. The CREATE TEMPORARY TABLES privilege is required, because Spider uses temporary tables to optimize read queries when Spider BKA Mode is 1.

Spider BKA Mode is configured using the following methods:

- The session value is configured by setting the Spider BKA Mode system variable on the Spider Node. The default value is -1. When the session value is -1, the value for each Spider Table is used.
- The value for each Spider Table is configured by setting the bka_mode option in the COMMENT table option. When the bka_mode option is not set, the implicit value is 1.

The default spider_bka_mode value is -1, and the implicit Spider Table value is 1, so the default Spider BKA Mode is 1.

On the Data Node hosting the new shard, grant the Spider user the CREATE TEMPORARY TABLES privilege on the database:

```
GRANT CREATE TEMPORARY TABLES ON southern_sales.* TO 'spider_user'@'192.0.2.1';
```

Alter the Spider Table

A partition for the new shard must be added to the Spider Table on the Spider Node.

On the Spider Node, alter the Spider Table to add the partition and reference the name of the Data Node hosting the new shard in the COMMENT partition option:

```
ALTER TABLE spider_sharded_sales.invoices
   ADD PARTITION (
      PARTITION southern_partition VALUES IN (4) COMMENT = 'server "southern_server", table "invoices"'
   );
```

Test Read Operations

On the Spider Node, read from the Spider Table using a SELECT statement:

```
SELECT * FROM spider_sharded_sales.invoices;
```

```
+-----------+------------+-------------+---------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date              | invoice_total | payment_method |
+-----------+------------+-------------+---------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |

Sharded MariaDB Enterprise Spider Topology Backup and Restore

Overview

When using Spider in the Sharded MariaDB Enterprise Spider topology, backup and restore operations can be performed using MariaDB Backup or MariaDB Dump. These operations must be performed on the Spider Node as well as on each Data Node.

MariaDB Backup

MariaDB Backup can be used to perform backup operations on Spider deployments.

Backup Spider with MariaDB Backup

MariaDB Backup can be used to create a physical backup of a Sharded MariaDB Enterprise Spider topology. MariaDB Backup must be used to backup the Spider Node and all Data Nodes. The Spider Node and Data Nodes must be locked to guarantee that the backups of the Spider Node and Data Nodes are consistent.

The backup of the Spider Node contains:

- Physical backup for Spider Tables
- Physical backup for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Physical backup for any other database objects on the Spider Node

The backups of the Data Nodes contain:

- Physical backup for Data Tables
- Physical backup for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Physical backup for any other database objects on the Data Node

The following procedure shows how to take a consistent backup of a Spider Node and Data Nodes deployed in a Sharded MariaDB Enterprise Spider topology.

1. On the Spider Node and on each Data Node, create a user account to perform the backup using the CREATE USER and GRANT statements.

For MariaDB Enterprise Server 10.5 and later:

```
CREATE USER 'mariadb-backup'@'localhost'
   IDENTIFIED BY 'mb_passwd';

GRANT RELOAD, PROCESS, LOCK TABLES, BINLOG MONITOR
   ON *.*
   TO 'mariadb-backup'@'localhost';
```

2. On each Data Node, grant the user account Spider uses when operating on Data Nodes sufficient privileges to lock any Data Tables using the GRANT statement.

For example, on the hq_server Data Node:

```
GRANT LOCK TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.2';
```

On the eastern_server Data Node:

```
GRANT LOCK TABLES ON eastern_sales.* TO 'spider_user'@'192.0.2.2';
```

On the western_server Data Node:

```
GRANT LOCK TABLES ON western_sales.* TO 'spider_user'@'192.0.2.2';
```

3. On the Spider Node, acquire a read lock on Spider Tables using the LOCK TABLES statement:

```
LOCK TABLES spider_sharded_sales.invoices READ;
```

Keep this session open during the rest of the procedure.

The read lock will propagate to the Data Tables on each Data Node as well. The read locks will prevent the Data Tables from changing during the backup, so the backups on the Spider Node and Data Nodes are consistent.

4. On each Data Node, perform the backup using MariaDB Backup .

With MariaDB Backup 10.5 and later, use the mariadb-backup command:

```
$ sudo mariadb-backup --backup \
   --target-dir=/data/backups/full \
   --user=mariadb-backup \
   --password='mb_passwd'
```

5. On the Spider Node, after backing up each Data Node, perform a backup with MariaDB Backup .

With MariaDB Backup 10.5 and later, use the mariadb-backup command:

```
$ sudo mariadb-backup --backup \
   --target-dir=/data/backups/full \
   --user=mariadb-backup \
   --password='mb_passwd'
```

6. On the Spider Node, after the backup is complete, in your original session, use the UNLOCK TABLES statement to release the table locks:

```
UNLOCK TABLES;
```

7. On the Spider Node and each of the Data Nodes, prepare each of the backups using MariaDB Backup.

With MariaDB Backup 10.5 and later, use the mariadb-backup command:

```
$ sudo mariadb-backup --prepare \
   --target-dir=/data/backups/full
```

The Spider Node and Data Nodes now each have a complete backup of the data directory. Backups should be tested to confirm they are complete and consistent.

Restore Spider with MariaDB Backup

MariaDB Backup can restore a Sharded MariaDB Enterprise Spider topology from a backup taken with MariaDB Backup.

1. On the Spider Node and on each Data Node, stop the MariaDB Server process:

```
$ sudo systemctl stop mariadb
```

2. On the Spider Node and on each Data Node, empty the data directory:

```
$ sudo rm -fr /var/lib/mysql/*
```

3. On the Spider Node and on each Data Node, restore the backup for that server using MariaDB Backup.

With MariaDB Backup 10.5 and later, use the mariadb-backup command:

```
$ sudo mariadb-backup --copy-back \
   --target-dir=/data/backups/full
```

4. On the Spider Node and on each Data Node, confirm that the restored files are owned by the user that owns the MariaDB Server process:

```
$ sudo chown -R mysql:mysql /var/lib/mysql
```

5. On the Spider Node and on each Data Node, start the MariaDB Server process:

```
$ sudo systemctl start mariadb
```

6. On the Spider Node, query a Spider Table to test it:

```
SELECT * FROM spider_sharded_sales.invoices;
```

```
+-----------+------------+-------------+----------------------------+---------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date               | invoice_total | payment_method |
+-----------+------------+-------------+----------------------------+---------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |
|         1 |          2 |           2 | 2020-05-10 14:17:32.000000 |       1508.57 | WIRE_TRANSFER  |
|         1 |          3 |           3 | 2020-05-10 14:25:16.000000 |        227.15 | CASH           |
|         2 |          1 |           2 | 2020-05-10 12:31:00.000000 |       1351.04 | CREDIT_CARD    |
|         2 |          2 |           2 | 2020-05-10 12:45:27.000000 |        162.11 | WIRE_TRANSFER  |
|         2 |          3 |           4 | 2020-05-10 13:11:23.000000 |        350.00 | CASH           |
|         3 |          1 |           5 | 2020-05-10 12:31:00.000000 |        111.50 | CREDIT_CARD    |
|         3 |          2 |           8 | 2020-05-10 12:45:27.000000 |       1509.23 | WIRE_TRANSFER  |
|         3 |          3 |           3 | 2020-05-10 13:11:23.000000 |       3301.66 | CASH           |
+-----------+------------+-------------+----------------------------+---------------+----------------+
```

MariaDB Dump

MariaDB Dump generates backup files containing the SQL statements necessary to recreate the database. MariaDB Dump is included with MariaDB Server and can be used to backup databases in Spider deployments. The MariaDB Client can then be used to restore databases from a MariaDB Dump backup.

Backup Spider with MariaDB Dump

MariaDB Dump can be used to create a logical backup of a Sharded MariaDB Enterprise Spider topology. MariaDB Dump must be used to backup the Spider Node and all Data Nodes. The Spider Node and Data Nodes must be locked to guarantee that the backups of the Spider Node and Data Nodes are consistent.

The backup of the Spider Node contains:

- Table definitions for Spider Tables
- Table definitions for all tables
- Table data for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Definitions for any other user accounts, privileges, views, and triggers on the Spider Node

The backups of the Data Nodes contain:

- Table definitions for Data Tables
- Table definitions for all tables
- Table data for tables that use InnoDB, Aria, MyISAM, and MyRocks
- Definitions for any other user accounts, privileges, views, and triggers on the Data Node

The following procedure shows how to take a consistent backup of a Spider Node and Data Nodes deployed in a Sharded MariaDB Enterprise Spider topology.

1. On the Spider Node and on each Data Node, create a user account to perform the backup using the CREATE USER and GRANT statements:

```
CREATE USER 'mariadb-dump'@'localhost'
   IDENTIFIED BY 'md_passwd';

GRANT SELECT, INSERT, SHOW VIEW, TRIGGER, CREATE, ALTER, EVENT, RELOAD, LOCK TABLES
   ON *.*
   TO 'mariadb-dump'@'localhost';
```

2. On each Data Node, grant the user account Spider uses to operate on the Data Nodes sufficient privileges to lock any Data Tables using the GRANT statement.

For example, on the hq_server Data Node:

```
GRANT LOCK TABLES ON hq_sales.* TO 'spider_user'@'192.0.2.2';
```

On the `eastern_server` Data Node:

```
GRANT LOCK TABLES ON eastern_sales.* TO 'spider_user'@'192.0.2.2';
```

On the `western_server` Data Node:

```
GRANT LOCK TABLES ON western_sales.* TO 'spider_user'@'192.0.2.2';
```

3. On the Spider Node, acquire a read lock on Spider Tables using the LOCK TABLES statement:

```
LOCK TABLES spider_sharded_sales.invoices READ;
```

Keep this session open during the rest of the procedure.

The read lock will propagate to the Data Tables on each Data Node as well. The read locks will prevent the Data Tables from changing during the backup, so the backups of the Spider Node and Data Nodes are consistent.

4. On each Data Node, perform the backup using MariaDB Dump.
   With MariaDB Dump 10.5 and later, use the mariadb-dump command:

```
$ mariadb-dump \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --all-databases \
   --single-transaction \
   --default-character-set=utf8mb4 \
   > mariadb_dump.sql
```

5. On the Spider Node, once the Data Nodes are backed up, perform a backup using MariaDB Dump.

With MariaDB Dump 10.5 and later, use the mariadb-dump command:

```
$ mariadb-dump \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --all-databases \
   --single-transaction \
   --default-character-set=utf8mb4 \
   > mariadb_dump.sql
```

6. On the Spider Node, after the backups are complete, in your original session use the UNLOCK TABLES statement to release the table locks:

```
UNLOCK TABLES;
```

The Spider Node and the Data Node now each have a mariadb_dump.sql backup file. This backup file contains the SQL statements needed to recreate the schema on the Spider Node and the schema and data on the Data Nodes. Backups should be tested to confirm they are complete and consistent.

Restore Spider from MariaDB Dump

MariaDB Client can restore a Sharded MariaDB Enterprise Spider topology from a backup taken with MariaDB Dump backup.

1. Stop all traffic to the Spider Node and each Data Node.
2. On the Spider Node, restore the backup for that server using MariaDB Client.

With MariaDB Client 10.5 and later, use the mariadb command:

```
$ mariadb \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --default-character-set=utf8mb4 \
   < mariadb_dump.sql
```

3. On the Data Node, restore the backup for that server using MariaDB Client.

With MariaDB Client 10.5 and later, use the mariadb command:

```
$ mariadb \
   --user=mariadb-dump \
   --password='md_passwd' \
   --ssl-verify-server-cert \
   --ssl-ca ~/mariadb_chain.pem \
   --default-character-set=utf8mb4 \
   < mariadb_dump.sql
```

4. On the Spider Node, query a Spider Table to test it:

```
SELECT * FROM spider_sharded_sales.invoices;
```

```
+-----------+------------+-------------+---------------------------+--------------+----------------+
| branch_id | invoice_id | customer_id | invoice_date              | invoice_total | payment_method |
+-----------+------------+-------------+---------------------------+--------------+----------------+
|         1 |          1 |           1 | 2020-05-10 12:35:10.000000 |       1087.23 | CREDIT_CARD    |

Spider Differences Between SpiderForMySQL and MariaDB

SQL Syntax

- With `SpiderForMySQL`, the CREATE TABLE statement uses `CONNECTION` to define spider table variables whereas MariaDB uses `COMMENT`.

Features

- HANDLER can not be translated to SQL in MariaDB
- Concurrent background search is not yet implemented in MariaDB
- Vertical partitioning storage engine VP is not implemented in MariaDB
- `CREATE TABLE` can use table discovery in MariaDB
- JOIN performance improvement using join_cache_level>1 `and` join_buffer_size in MariaDB

This page is licensed: CC BY-SA / Gnu FDL

Spider Feature Matrix

Not complete yet - still being updated

F*()* *Federation only, P()*partitioning only.
Spider column is for SpiderForMySQL found on the Spider web sIte.

Feature	Spider	10.0
Clustering and High Availability		
Commit, Rollback transactions on multiple backend	Yes	Yes
Multiplexing to a number of replicas using xa protocol 2PC	Yes	Yes
Split brain resolution based on a majority decision, failed node is remove from the list of replicas	Yes	Yes

Feature	Spider	10.0
Enable a failed backend to re enter the cluster transparently	No	No
Synchronize DDL to backend, table modification, schema changes	No	No
Synchronize DDL to other Spider	No	No
GTID tracking per table on XA error	No	Yes
Transparent partitioning	No	No
Covered by generic SQL test case	Yes	Yes
Heterogeneous Backends		
MariaDB and MySQL database backend	Yes	Yes
Oracle database backend, if build from source against the client library ‘ORACLE_HOME’	Yes	Yes
Local table attachment	Yes	Yes
Performance		
Index Condition Pushdown	No	No
Engine Condition Pushdown	Yes	Yes
Concurrent backend scan	Yes	No
Concurrent partition scan	Yes	No
Batched key access	Yes	Yes
Block hash join	No	Yes
HANDLER backend propagation	Yes	Yes
HANDLER backend translation from SQL	Yes	Yes
HANDLER OPEN cache per connection	No	Yes
HANDLER use prepared statement	No	Yes
HANDLER_SOCKET protocol backend propagation	Yes	Yes
HANDLER_SOCKET backend translation from SQL	No	No
Map reduce for ORDER BY … LIMIT	Yes	Yes
Map reduce for MAX & MIN & SUM	Yes	Yes
Map reduce for some GROUP BY	Yes	Yes
Batch multiple WRITES in auto commit to reduce network round trip	Yes	Yes
Relaxing backend consistency	Yes	Yes
Execution Control		
Configuration at table and partition level, settings can change per data collection	Yes	Yes
Configurable empty result set on errors. For API that does not have transactions replay	Yes	Yes
Query Cache tuning per table of the on remote backend	Yes	Yes
Index Hint per table imposed on remote backend	Yes	Yes
SSL connections to remote backend connections	Yes	Yes
Table definition discovery from remote backend	Yes	F(*)
Direct SQL execution to backend via UDF	Yes	Yes
Table re synchronization between backends via UDF	Yes	Yes
Maintain Index and Table Statistics of remote backends	Yes	Yes
Can use Independent Index and Table Statistics	No	Yes

Feature	Spider	10.0
Maintain local or remote table increments	Yes	Yes
LOAD DATA INFILE translate to bulk inserting	Yes	Yes
Performance Schema Probes	Yes	Yes
Load Balance Reads to replicate weight control	Yes	Yes
Fine tuning tcp timeout, connections retry	Yes	Yes

Spider Use Cases

Introduction

This article will cover simple working examples for some standard use cases for Spider. The example are illustrated using a sales opportunities table to be consistent throughout. In some cases the actual examples are contrived but are used to illustrate the varying syntax options.

Basic setup

Have 3 or more servers available and Install MariaDB on each of these servers:

- spider server which will act as the front end server hosting the spider storage engine.
- backend1 which will act as a backed server storing data
- backend2 which will act as a second backend server storing data

Follow the instructions here to enable the Spider storage engine on the spider server:

```
INSTALL SONAME 'ha_spider';
```

Setting the SUPER privilege for the Spider user on data nodes or alternatives to avoid privilege issues

When explicitly setting the spider_internal_sql_log_off system variable, please note that Spider will execute matching SET SQL_LOG_OFF statements on each of the data nodes. It will attempt to do this on the data nodes using the SUPER privilege, which thus requires one to grant this privilege to the Spider user on the data nodes.

If the Spider user on the data note is not configured with the SUPER privilege, you may encounter issues when working with Spider tables like ERROR 1227 (42000): Access denied for the missing SUPER privilege. To avoid this, don't explicitly set spider_internal_sql_log_off, or set it to -1, or grant the SUPER privilege to the Spider user on the data node.

Create accounts for spider to connect with on backend servers

Spider needs a remote connection to the backend server to actually perform the remote query. So this should be setup on each backend server. In this case 172.21.21.2 is the ip address of the spider node limiting access to just that server.

```
backend1> mysql
GRANT ALL ON test.* TO spider@'172.21.21.2' IDENTIFIED BY 'spider';
backend2> mysql
GRANT ALL ON test.* TO spider@'172.21.21.2' IDENTIFIED BY 'spider';
```

Now verify that these connections can be used from the spider node (here 172.21.21.3 = backend1 and 172.21.21.4 = backend2):

```
spider> mysql -u spider -p -h 172.21.21.3 test
spider> mysql -u spider -p -h 172.21.21.4 test
```

Create table on backend servers

The table definition should be created in the test database on both backend1 and backend2 servers:

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11),
PRIMARY KEY (id),
KEY (accountName)
) ENGINE=InnoDB;
```

Create server entries on spider server

While the connection information can also be specified inline in the comment or (from MariaDB 10.8.1) as table options, it is cleaner to define a server object representing each remote backend server connection:

```
CREATE SERVER backend1 FOREIGN DATA WRAPPER MYSQL OPTIONS
(HOST '172.21.21.3', DATABASE 'test', USER 'spider', PASSWORD 'spider', PORT 3306);
CREATE SERVER backend2 FOREIGN DATA WRAPPER MYSQL OPTIONS
(HOST '172.21.21.4', DATABASE 'test', USER 'spider', PASSWORD 'spider', PORT 3306);
```

Unable to Connect Errors

Bear in mind, if you ever need to remove, recreate or otherwise modify the server definition for any reason, you need to also execute a FLUSH TABLES statement. Otherwise, Spider continues to use the old server definition, which can result in queries raising the error

```
Error 1429: Unable to connect to foreign data source
```

If you encounter this error when querying Spider tables, issue a FLUSH TABLES statement to update the server definitions.

```
FLUSH TABLES;
```

Use case 1: remote table

In this case, a spider table is created to allow remote access to the opportunities table hosted on backend1. This then allows for queries and remote dml into the backend1 server from the spider server:

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11),
PRIMARY KEY (id),
KEY (accountName)
) ENGINE=spider COMMENT='wrapper "mysql", srv "backend1" , TABLE "opportunities"';
```

Use case 2: sharding by hash

See also hash-partitioning-type.

In this case a spider table is created to distribute data across backend1 and backend2 by hashing the id column. Since the id column is an incrementing numeric value the hashing will ensure even distribution across the 2 nodes.

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11),
PRIMARY KEY (id),
KEY (accountName)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "opportunities"'
 PARTITION BY HASH (id)
(
 PARTITION pt1 COMMENT = 'srv "backend1"',
 PARTITION pt2 COMMENT = 'srv "backend2"'
) ;
```

Use case 3: sharding by range

See also range-partitioning-type.

In this case a spider table is created to distribute data across backend1 and backend2 based on the first letter of the accountName field. All accountNames that start with the letter L and prior are stored in backend1 and all other values stored in backend2. Note that the accountName column must be added to the primary key which is a requirement of MariaDB partitioning:

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11),
PRIMARY KEY (id, accountName),
KEY(accountName)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "opportunities"'
 PARTITION BY RANGE COLUMNS (accountName)
(
 PARTITION pt1 VALUES LESS THAN ('M') COMMENT = 'srv "backend1"',
 PARTITION pt2 VALUES LESS THAN (MAXVALUE) COMMENT = 'srv "backend2"'
) ;
```

Use case 4: sharding by list

See also list-partitioning-type.

In this case a spider table is created to distribute data across backend1 and backend2 based on specific values in the owner field. Bill, Bob, and Chris are stored in backend1 and Maria and Olivier stored in backend2. Note that the owner column must be added to the primary key which is a requirement of MariaDB partitioning:

```
CREATE TABLE opportunities (
id INT,
accountName VARCHAR(20),
name VARCHAR(128),
owner VARCHAR(7),
amount DECIMAL(10,2),
closeDate DATE,
stageName VARCHAR(11),
PRIMARY KEY (id, owner),
KEY(accountName)
) ENGINE=spider COMMENT='wrapper "mysql", TABLE "opportunities"'
 PARTITION BY LIST COLUMNS (owner)
(
 PARTITION pt1 VALUES IN ('Bill', 'Bob', 'Chris') COMMENT = 'srv "backend1"',
 PARTITION pt2 VALUES IN ('Maria', 'Olivier') COMMENT = 'srv "backend2"'
) ;
```

With MariaDB 10.2 the following partition clause can be used to specify a default partition for all other values, however this must be a distinct partition / shard:

```
PARTITION partition_name DEFAULT
```

For a complete list of partition types, see partitioning-types.

Spider Installation

The Spider storage engine supports partitioning and XA transactions, and allows tables of different database host instances to be handled as if they were on the same instance.

To make sensible use of Spider, you need two or more database host instances, typically running on separate hosts. Those database instances can be two or more MariaDB Server hosts, or a MariaDB Server host and an Oracle Database, etc. The Spider node is the MariaDB server that receives queries from your application. It then processes these queries, connecting to one or more data nodes. The data nodes are the MariaDB servers that actually store the table data.

In order for this to work, you need to configure the data nodes to accept queries from the Spider node and you need to configure the Spider node to use the data nodes as remote storage.

You don't need to install any additional packages to use it, but it does require some configuration.

Configuring Data Nodes

Spider deployments use data nodes to store the actual table data. In order for a MariaDB server to operate as a data node for Spider, you need to create a table or tables on which to store the data and configure the server to accept client connections from the Spider node.

For instance, first create the table:

```
CREATE TABLE test.spider_example (
   id INT PRIMARY KEY AUTO_INCREMENT,
   name VARCHAR(50)
) ENGINE=InnoDB;
```

Next, create a user for the Spider node and set a password for that user. For the sake of the example, assume the Spider node is at the IP address 192.168.1.1:

```
CREATE USER spider@192.168.1.1;

SET PASSWORD FOR spider@192.168.1.1 = PASSWORD('passwd');
```

Then grant the `spider` user privileges on the example table.

```
GRANT ALL ON test.spider_example TO spider@192.168.1.1;
```

The data node is now ready for use. You can test it by attempting to connect the MariaDB client to the data from the Spider node. For instance, assuming the data node is at the IP address 192.168.1.5, SSH into the Spider node then try to establish a client connection.

```
$ mysql -u spider -p -h 192.168.1.5 test -e "SHOW TABLES;"
+----------------+
| Tables_in_test |
+----------------+
| spider_example |
+----------------+
```

Install Spider on Spider Node

The Spider storage engine must be installed on the Spider node. The Spider node is the MariaDB server that receives queries for the table, (in this case `test.spider_example`). It then uses the Spider storage engine to connect to the tables on the data nodes to retrieve data and return the result-set.

To install the Spider storage engine, complete the installation process shown below.

Step 1: Install Spider Package

APT

APT (Debian, Ubuntu, etc.)

To install the Spider storage engine, execute the following command:

```
$ sudo apt install mariadb-plugin-spider
```

YUM

YUM (CentOS etc.)

To install the Spider storage engine, execute the following command:

```
sudo yum install MariaDB-spider-engine
```

OTHER LINUX DISTRIBUTIONS

On other Linux distributions, the Spider storage engine is installed with MariaDB Server.

Step 2: Load the Spider Plugin

The Spider storage engine can be loaded as a normal plugin, and Spider automatically creates its dependencies. There are two primary ways to load the plugin.

The plugin can be loaded dynamically without a server restart by executing `INSTALL SONAME` or `INSTALL PLUGIN`:

```
INSTALL SONAME "ha_spider";
```

Alternatively, the plugin can be loaded by adding `plugin_load_add=ha_spider` to a configuration file:

```
[mariadb]
...
plugin_load_add = "ha_spider"
```

If the plugin is loaded in a configuration file, then the server will load the plugin after the server has been restarted.

Loading the plugin also creates a series of new tables in the `mysql` database, including:

- spider_xa
- spider_xa_member
- spider_xa_failed_log
- spider_tables
- spider_link_mon_servers
- spider_link_failed_log
- spider_table_position_for_recovery
- spider_table_sts
- spider_table_crd

Step 3: Verify Loading of the Spider Plugin

You can verify that the Spider plugin has been loaded by querying the `information_schema.ENGINES` table:

```
SELECT ENGINE, SUPPORT
FROM information_schema.ENGINES
WHERE ENGINE = 'SPIDER';
+--------------------+---------+
| ENGINE             | SUPPORT |
+--------------------+---------+
| SPIDER             | YES     |
+--------------------+---------+
```

If the Spider plugin is not loaded, then the query does not return any results.

Configuring Spider Nodes

With the data node or data nodes configured, you can set up the Spider node to use them. The Spider node is the MariaDB server that receives queries for the table, (in this case `test.spider_example`). It then uses the Spider storage engine to connect to the tables on the data nodes to retrieve data and return the result-set.

Configure the Server

In order to connect the Spider node to the data nodes, you may issue a CREATE SERVER statement for each data node. You can then use the server definition in creating the Spider table.

```
CREATE SERVER dataNode1 FOREIGN DATA WRAPPER mysql
OPTIONS (
   HOST '192.168.1.5',
   DATABASE 'test',
   USER 'spider',
   PASSWORD 'passwd',
   PORT 3306);
```

In the event that you need to modify or replace this server after setting up the Spider table, remember to issue a FLUSH statement to update the server definition.

```
FLUSH TABLES;
```

Alternatively, you could also choose not to create a server, but specify the connection info in the spider table creation.

Create the Table

With the data nodes set up and the Spider node configured for use, you can create the Spider table. The Spider table must have the same column definitions as the tables on the data nodes. Spider can be configured through table parameters passed to the `COMMENT` or `CONNECTION` option.

```
CREATE TABLE test.spider_example (
   id INT PRIMARY KEY AUTO_INCREMENT,
   name VARCHAR(50)
) ENGINE=Spider
COMMENT='wrapper "mysql", srv "dataNode1", table "spider_example"';
```

This configures Spider to use the server `dataNode1`, (defined above), as a remote table. Any data you write to this table is actually stored on the MariaDB server at 192.168.1.5.

Alternatively, starting from MariaDB 10.8.1, one can specify spider table parameters using table options:

```
CREATE TABLE test.spider_example (
   id INT PRIMARY KEY AUTO_INCREMENT,
   name VARCHAR(50)
) ENGINE=Spider
REMOTE_SERVER=dataNode1 REMOTE_TABLE=spider_example;
```

This page is licensed: CC BY-SA / Gnu FDL

Spider Cluster Management

Direct SQL

Direct SQL is a way to map reduced execution on remote backends and store the results in a local table. This can either be sequential, using the UDF function spider_direct_sql, or concurrently, using spider_bg_direct_sql.

```
spider1 backend << EOF
CREATE TEMPORARY TABLE res
(
  id INT(10) UNSIGNED NOT NULL,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT ''
) ENGINE=MEMORY;

SELECT spider_direct_sql(
'SELECT * FROM sbtest s  WHERE s.id IN(10,12,13)',
  'res',
  concat('host "', host, '", port "', port, '", user "', username, '", password "', password, '",
database "', tgt_db_name, '"')
) a
FROM
  mysql.spider_tables
WHERE
  db_name = 'backend' AND table_name LIKE 'sbtest#P#pt%';

SELECT * FROM res;
EOF
```

Or if you are using a SERVER:

```
SELECT spider_direct_sql(
  'SELECT * FROM sbtest s  WHERE s.id IN(10,12,13)',
  'res',
  concat('server "', server, '"')
) a
  FROM mysql.spider_tables
  WHERE db_name = 'backend' AND table_name LIKE 'sbtest#P#pt%' ;
```

The default for spider_bg_direct_sql is to access concurrently all backends. If you have multiple partitions store inside a single backend, you still can increase parallelism affecting different channels to each partitions.

```
CREATE TEMPORARY TABLE res
(
  id INT(10) UNSIGNED NOT NULL ,
  col_microsec DATETIME(6) DEFAULT NOW(8),
  db VARCHAR(20)
) ENGINE=MEMORY;

SELECT spider_bg_direct_sql( 'SELECT count(*) ,min(NOW(6)),min(DATABASE())) FROM sbtest',   'res',
concat('srv "', server,'" cch ',@rn:=@rn+1  ) ) a  FROM    mysql.spider_tables,(SELECT @rn:=1) t2  WHERE
db_name = 'bsbackend' AND table_name LIKE 'sbtest#P#pt%';
```

Direct Handler Socket

MariaDB starting with 10.8.1

The Spider Handler Socket support has been removed, see MDEV-26858.

Check that Handler Socket is running on the backend nodes

```
:~# backend2 -e "show variables like 'handler%'"
+------------------------------+---------------+
| Variable_name                | Value         |
+------------------------------+---------------+
| handlersocket_accept_balance | 0             |
| handlersocket_address        | 192.168.0.201 |
| handlersocket_backlog        | 32768         |
| handlersocket_epoll          | 1             |
| handlersocket_plain_secret   |               |
| handlersocket_plain_secret_wr |               |
| handlersocket_port           | 20500         |
| handlersocket_port_wr        | 20501         |
| handlersocket_rcvbuf         | 0             |
| handlersocket_readsize       | 0             |
| handlersocket_sndbuf         | 0             |
| handlersocket_threads        | 4            |
| handlersocket_threads_wr     | 1             |
| handlersocket_timeout        | 300           |
| handlersocket_verbose        | 10            |
| handlersocket_wrlock_timeout | 12            |
+------------------------------+---------------+
```

```
spider1 backend << EOF
CREATE TEMPORARY TABLE res
(
  id INT(10) UNSIGNED NOT NULL,
  k INT(10) UNSIGNED NOT NULL DEFAULT '0',
  c CHAR(120) NOT NULL DEFAULT '',
  pad CHAR(60) NOT NULL DEFAULT ''
) ENGINE=MEMORY;

SELECT spider_direct_sql('1\t=\t1\t2\t100000\t0','res', 'host "192.168.0.202", table "sbtest", database
"test", port "20500", access_mode "1"');
```

Inter Nodes Copy Table

MariaDB starting with 10.8.1

The UDF spider_copy_tables relies on Spider's high availability feature, which has been deprecated (MDEV-28479), and are deleted. Please use other high availability solutions like replication or galera-cluster.

The UDF function spider_copy_tables is available for copying table data from the source link ID to the destination link ID list without stopping your service for copying

```
spider_copy_tables(Spider table name, source link ID, destination link ID list[, parameters])
```

- `Returns 1` if copying data succeeded.
- `Returns 0` if copying data failed.

If the Spider table is partitioned, you must set "Spider table name" with a part name such as "table_name#P#part_name".

You can check the table name and the link ID with the part name using the following SQL:

```
SELECT table_name FROM mysql.spider_tables;
```

General Log

To capture all queries sent to remote backends on a `Spider Node` :

```
SET GLOBAL general_log=ON;
SET GLOBAL spider_general_log=ON;
SET GLOBAL spider_log_result_errors=1;
SET GLOBAL spider_log_result_error_with_sql=3;
```

Compiling in Debug Mode

See Compiling MariaDB for Debugging and Creating a Trace File.

Report the issue in MariaDB JIRA (see Reporting Bugs) or to the MariaDB Corporation support center.

Compiling in Static

Available since version 3.1.14

To activate spider as a static plugin change "MODULE_ONLY" to "MANDATORY" in storage/spider/CMakeList.txt before compiling

Note that Spider UDF functions will not work with such settings.

Status Variables

A number of new status variables have been introduced, see Spider Status Variables for a complete list.

Information Schema Tables

- A new Information Schema table is installed - SPIDER_ALLOC_MEM.

```
+-------------------+---------------------+------+-----+---------+-------+
| Field             | Type                | Null | Key | Default | Extra |
+-------------------+---------------------+------+-----+---------+-------+
| ID                | int(10) unsigned    | NO   |     | 0       |       |
| FUNC_NAME         | varchar(64)         | YES  |     | NULL    |       |
| FILE_NAME         | varchar(64)         | YES  |     | NULL    |       |
| LINE_NO           | int(10) unsigned    | YES  |     | NULL    |       |
| TOTAL_ALLOC_MEM   | bigint(20) unsigned | YES  |     | NULL    |       |
| CURRENT_ALLOC_MEM | bigint(20)          | YES  |     | NULL    |       |
| ALLOC_MEM_COUNT   | bigint(20) unsigned | YES  |     | NULL    |       |
| FREE_MEM_COUNT    | bigint(20) unsigned | YES  |     | NULL    |       |
+-------------------+---------------------+------+-----+---------+-------+
```

From MariaDB 10.5, Spider installs another Information Schema table, SPIDER_WRAPPER_PROTOCOLS.

Performance Schema

The Performance schema is commonly used to troubleshoot issues that consume time inside your workload. The Performance schema should not be activated for servers that are experimenting constant heavy load, but most of time it is acceptable to lose 5% to 20% additional CPU to keep track of server internals execution.

To activate the performance schema, use the performance_schema system variable and add the following to the server section of the MariaDB configuration file.

```
performance_schema=ON
```

Activate the Spider probes to be monitored.

```
UPDATE performance_schema.setup_instruments SET
  ENABLED='YES', TIMED='yes' WHERE NAME LIKE '%spider%';
```

Run your queries …

And check the performance metrics. Remove specific Spider metrics to have a more global view.

```
SELECT * FROM performance_schema.events_waits_summary_global_by_event_name
  WHERE COUNT_STAR<>0 AND EVENT_NAME LIKE '%spider%'
  ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

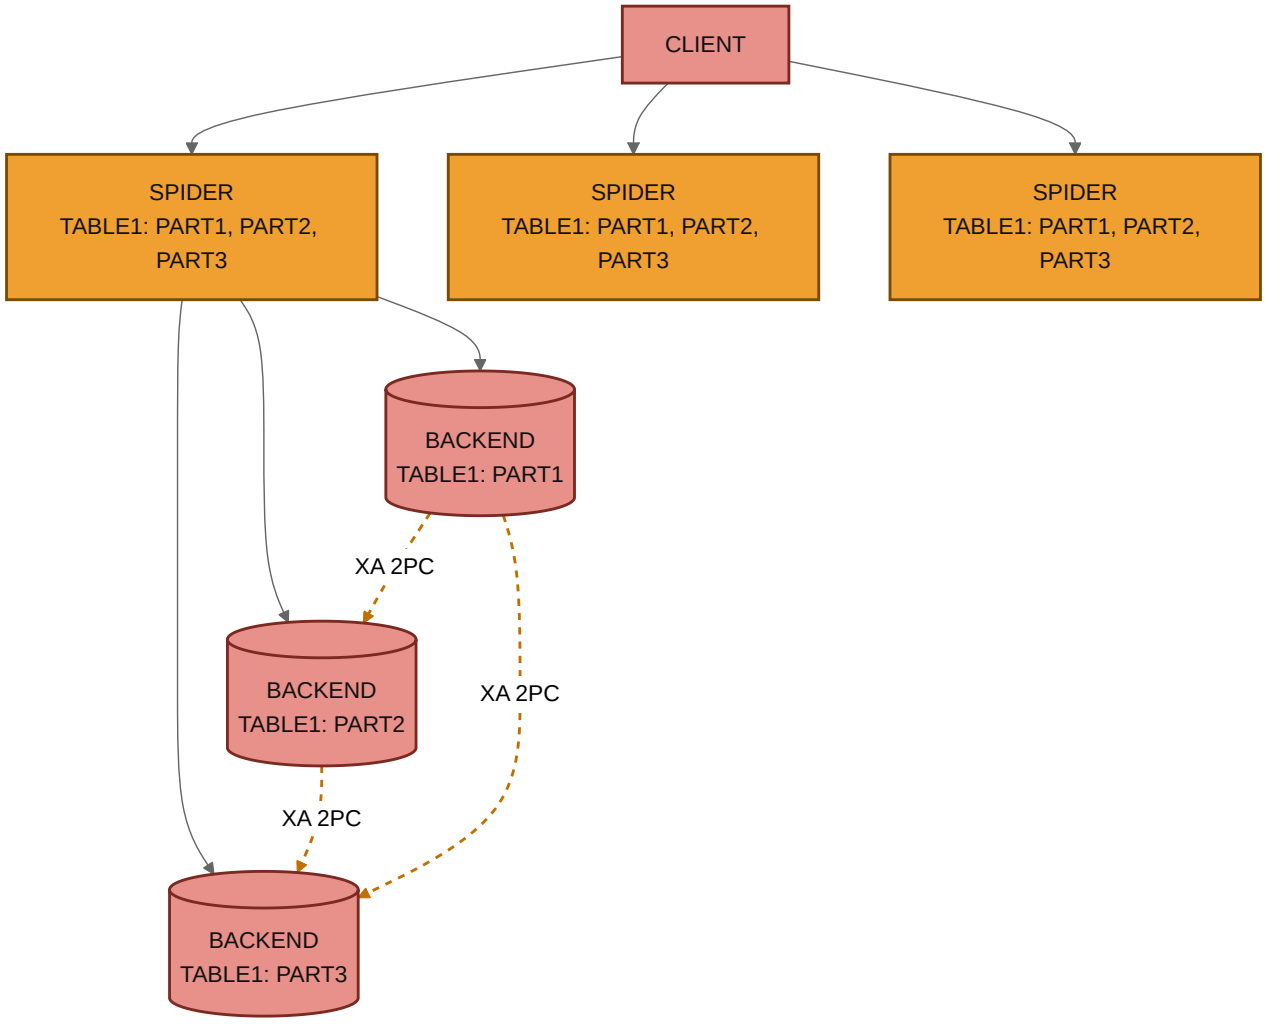
Spider Benchmarks

This is best run on a cluster of 3 nodes intel NUC servers 12 virtual cores model name : Intel® Core(TM) i3-3217U CPU @ 1.80GHz

All nodes have been running a mysqlslap client attached to the local spider node in the best run.

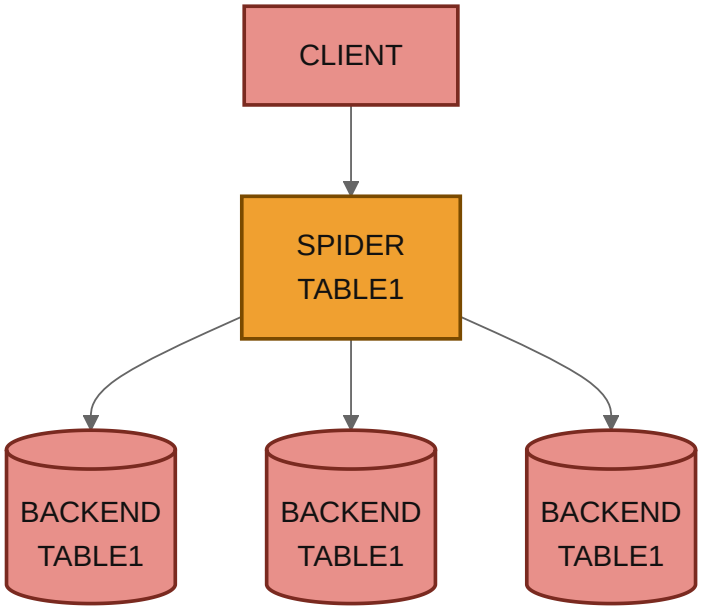
```
/usr/local/skysql/mysql-client/bin/mysqlslap --user=skysql --password=skyvodka --host=192.168.0.201 --
port=5012 -i1000000 -c32 -q "insert into test(c) values('0-31091-138522330')" --create-schema=test
```

`spider_conn_recycle_mode=1;`



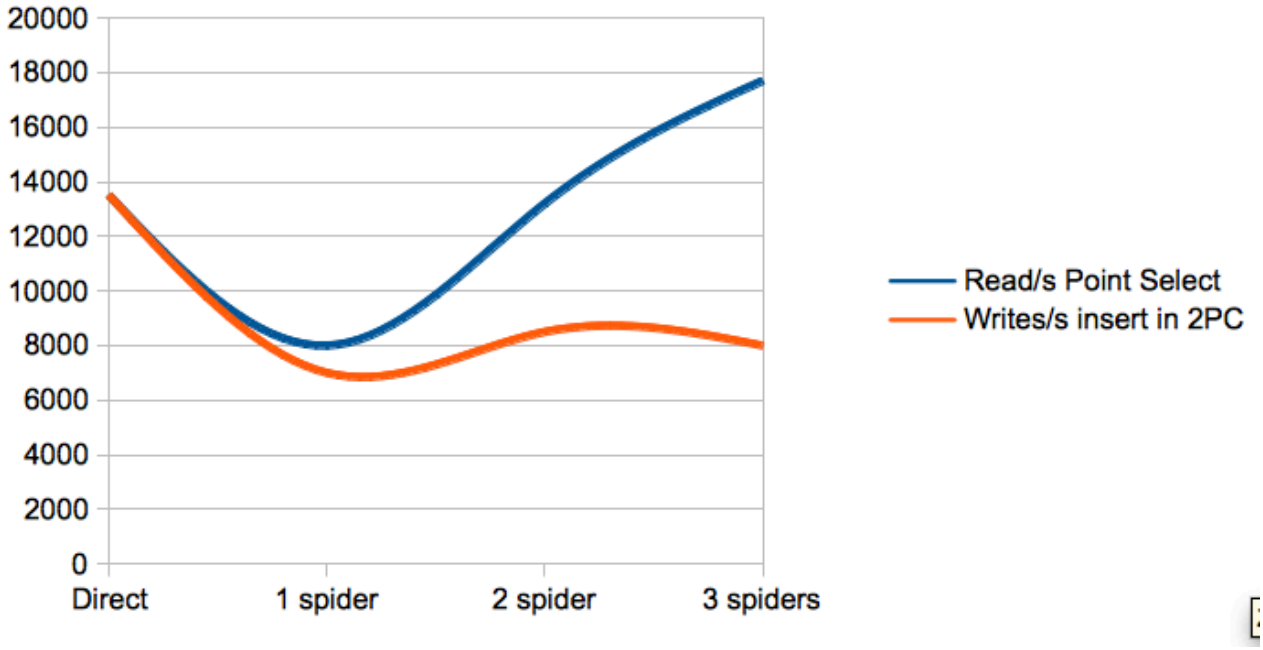
Spider sharding architecture: three Spider nodes route to three backend shards, each holding one partition of TABLE1, coordinated across backends by XA two-phase commit.

The read point select is produce with a 10M rows sysbench table



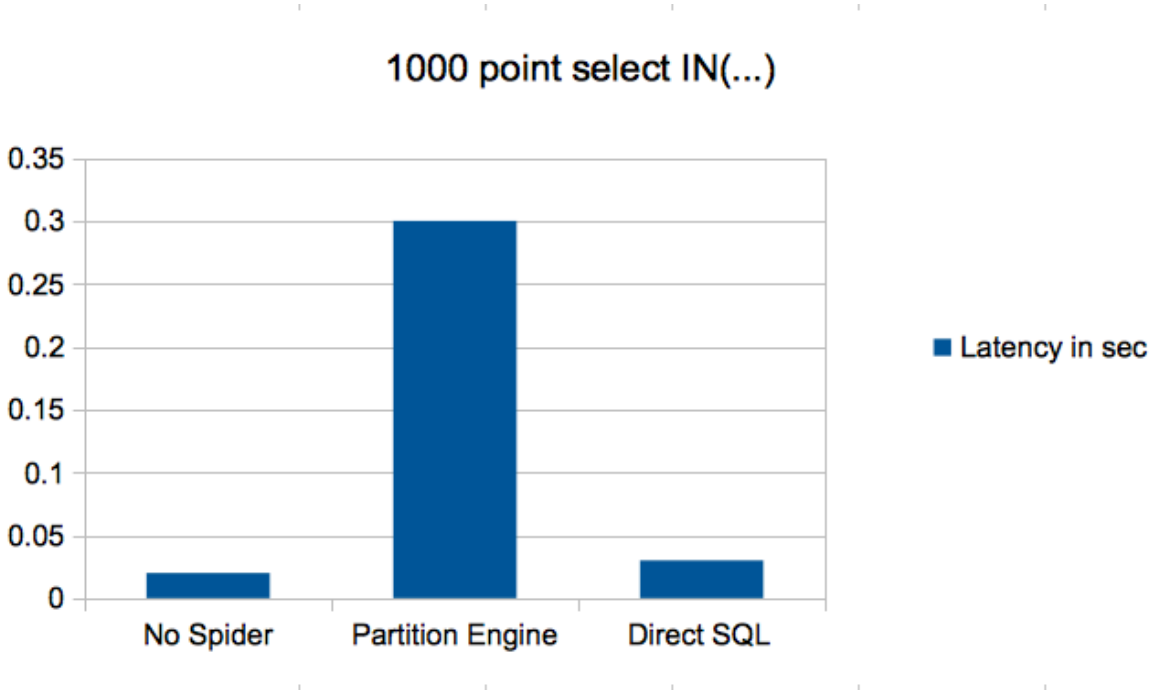
Single Spider node distributing client queries to three backend nodes, each holding a full copy of TABLE1.

The write insert a single string into a memory table



spbench6

Before Engine Condition Push Down patch .



benchspider7

Spider can benefit by 10% additional performance with Independent Storage Engine Statistics.

```
SET global use_stat_tables='preferably';
USE backend;
ANALYZE TABLE sbtest;
```

Information Schema SPIDER_WRAPPER_PROTOCOLS Table

MariaDB starting with 10.5.4

The Information Schema `SPIDER_WRAPPER_PROTOCOLS` table is installed along with the Spider storage engine from MariaDB 10.5.4.

It contains the following columns:

Column	Type	Description
WRAPPER_NAME	varchar(64)	
WRAPPER_VERSION	varchar(20)	
WRAPPER_DESCRIPTION	longtext	
WRAPPER_MATURITY	varchar(12)	

This page is licensed: CC BY-SA / Gnu FDL

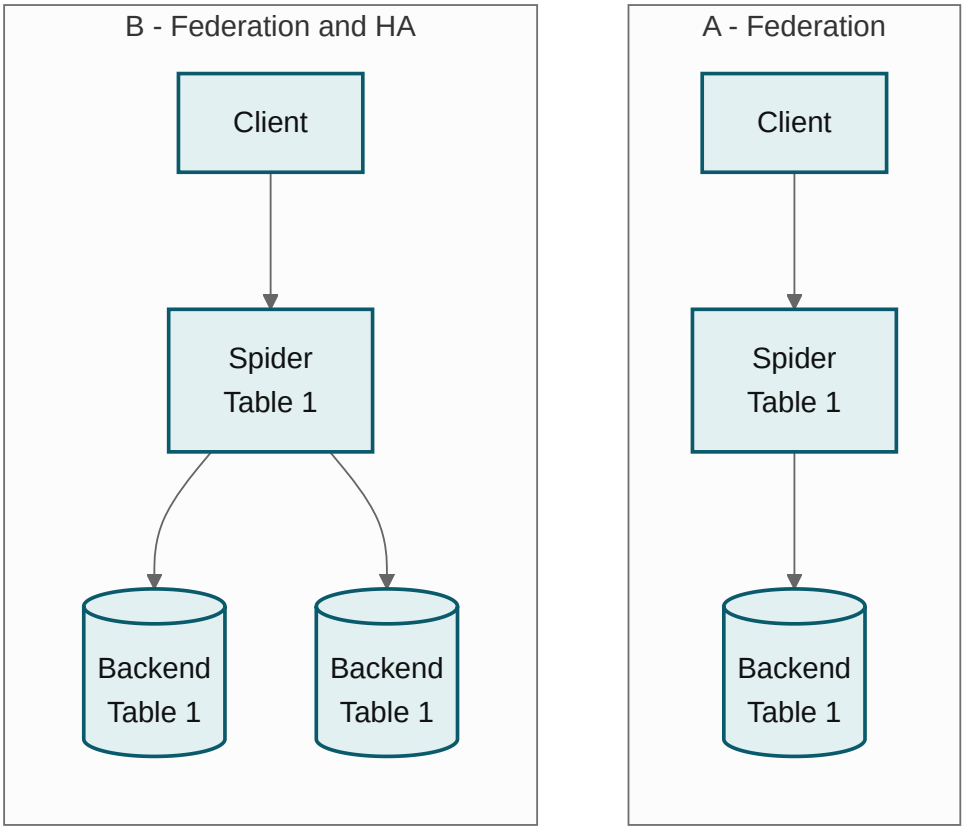
Spider Storage Engine Core Concepts

A typical Spider deployment has a shared-nothing clustered architecture. The system works with any inexpensive hardware, and with a minimum of specific requirements for hardware or software. It consists of a set of computers, with one or more MariaDB processes known as nodes.

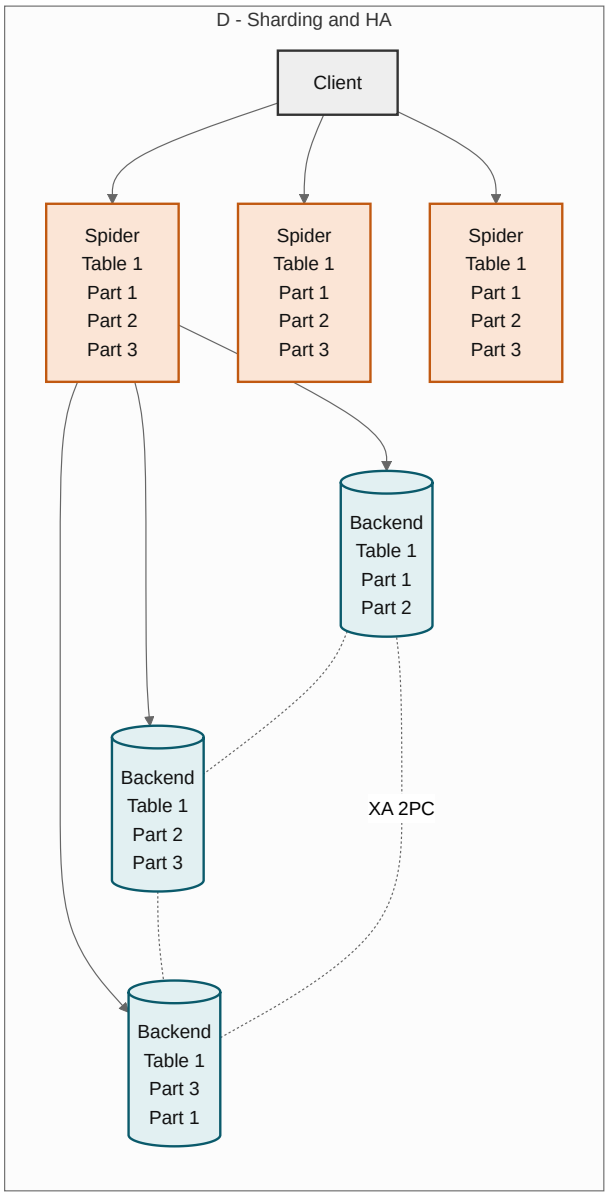
The nodes that store the data are designed as `Backend Nodes`, and can be any MariaDB, MySQL, Oracle server instances using any storage engine available inside the backend.

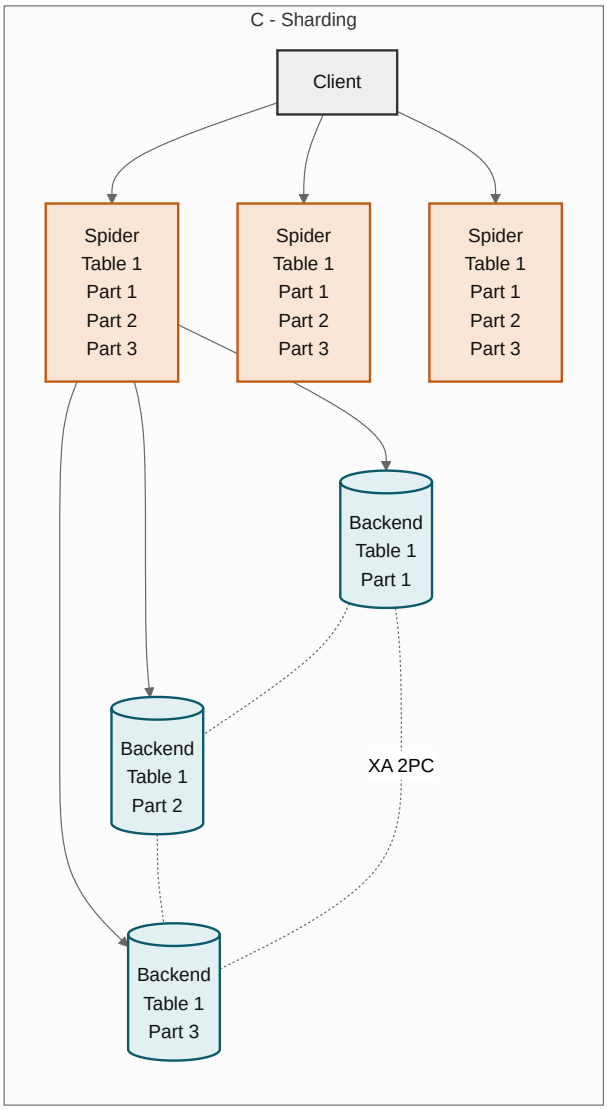
The `Spider Proxy Nodes` are instances running at least MariaDB 10. `Spider Proxy Nodes` are used to declare per table attachment to the backend nodes. In addition `Spider Proxy Nodes` can be setup to enable the tables to be split and mirrored to multiple `Backend Nodes`.

Spider Common Usage



Topology A (federation) routes a client through Spider to a single backend node; topology B (federation with HA) routes the same client through Spider to two redundant backend nodes.





Topology C (sharding) routes a client through three Spider nodes to three non-overlapping backend shards; topology D (sharding with HA) uses the same Spider layer but stores each partition redundantly across two backend shards, all coordinated via XA two-phase commit.

In the default high availability setup Spider Nodes produce SQL errors when a backend server is not responding. Per table monitoring can be setup to enable availability in case of unresponsive backends `monotoring_bg_kind=1` or `monotoring_bg_kind=2`. The Monitoring Spider Nodes are inter-connected with usage of the system table `mysql.link_mon_servers` to manage network partitioning. Better known as split brain, an even number of `Spider Monitor Nodes` should be setup to allow a consensus based on the majority. Rather a single separated shared `Monitoring Node` instance or a minimum set of 3 `Spider Nodes`. More information can be found here.

MariaDB starting with 10.7.5

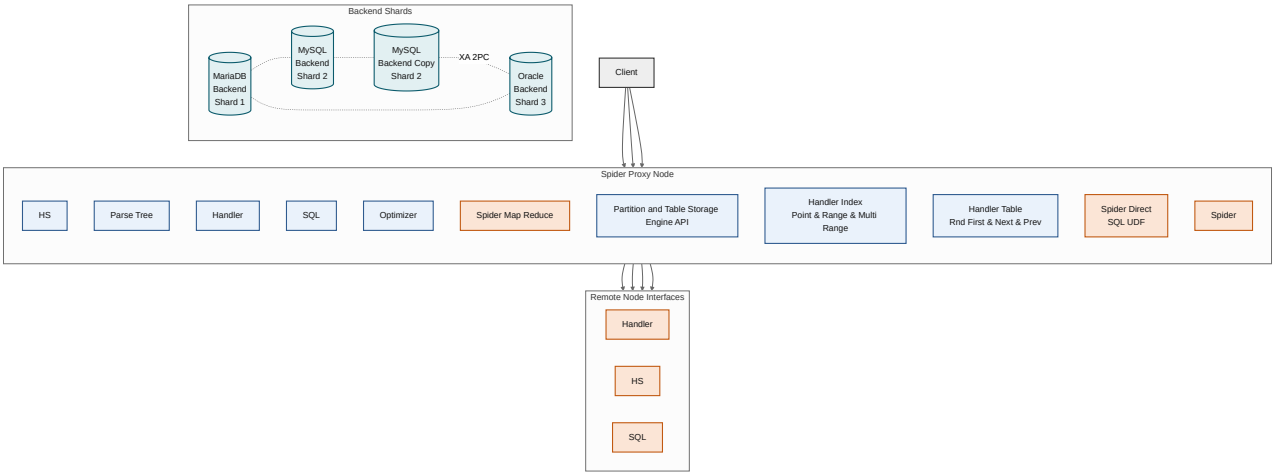
Spider's high availability feature has been deprecated (MDEV-28479), and are deleted. Please use other high availability solutions like replication or galera-cluster.

Spider Storage Engine Federation

Spider is a pluggable Storage Engine, acting as a proxy between the optimizer and the remote backends. When the optimizer requests multiple calls to the storage engine, Spider enforces consistency using the 2 phase commit

protocol to the backends and by creating transactions on the backends to preserve atomic operations for a single SQL execution.
Preserving atomic operation during execution is used at multiple levels in the architecture. For the regular optimizer plan, it refers to `multiple split reads` and for concurrent partition scans, it will refer to `semi transactions`.

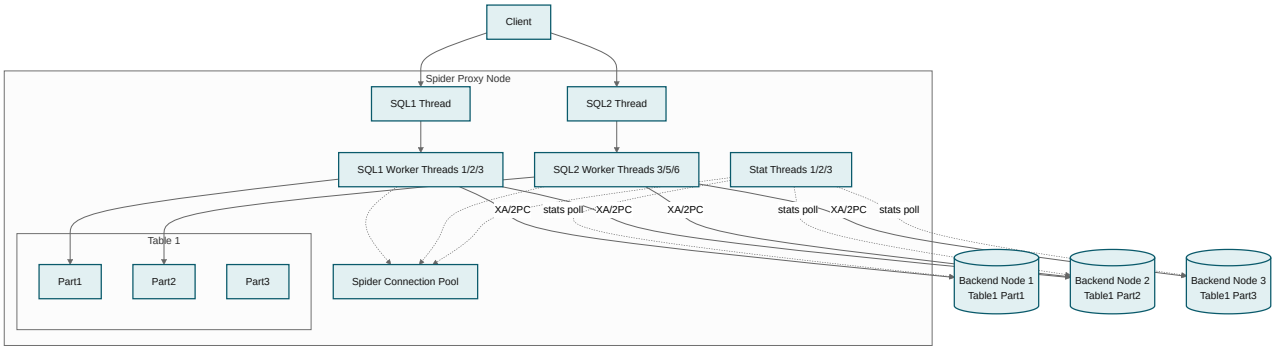
Costly queries can be more efficient when it is possible to fully push down part of the execution plan on each backend and reduce the result afterwards. Spider enables such execution with some direct execution shortcuts.



The Spider proxy node layers client-facing Handler, HS, and SQL interfaces (plus the optimizer, partition API, and Spider Map Reduce/Direct SQL UDF extensions) over the core Spider engine, which forwards to remote node interfaces fronting four backend shards kept consistent via XA two-phase commit.

Spider Threading Model

Spider uses the per partitions and per table model to concurrently access the remote backend nodes. For memory workload that property can be used to define multiple partitions on a single remote backend node to better adapt the concurrency to available CPUs in the hardware.



Spider's per-partition, per-table threading model: SQL1/SQL2 worker threads coordinate over a shared connection pool and commit via XA two-phase commit across three backend nodes, while stat threads poll statistics independently.

Spider maintains an internal dictionary of Table and Index statistics based on separated threads. The statistics are pulled per default on a time line basis and refer to `crd` for cardinality and `sts` for table status.

Spider Memory Model

Spider stores resultsets into memory, but spider_quick_mode=3 stores resultsets into internal temporary tables if the resultsets are larger than quick_table_size.

Specifying Connection Information for Spider Tables

Spider tables connect to remote servers by reading connection information from one or more sources. MariaDB supports several methods for defining this information, each introduced at different versions. When more than one method is present, a defined precedence order determines which takes effect.

Connection information for Spider tables can be provided in different ways:

- Foreign server options (using `CREATE SERVER`)
- `CONNECTION` or `COMMENT` strings
- Engine-defined options (such as `REMOTE_SERVER`, `REMOTE_DATABASE`, and `REMOTE_TABLE`)

Connection information for Spider tables can also be specified for different levels, where partition-level info overrides table-level info.

Spider has a predefined precedence order when using multiple methods.

Applies to both CS and ES

The following behavior applies to both CS and ES:

- Connection specification methods: (foreign server options, `COMMENT` string, `CONNECTION` string, and engine-defined options).
- Precedence rules (engine-defined options > `COMMENT` string > `CONNECTION` string > foreign server options; partition-level overrides table-level)
- Version-based behavior, such as the deprecation of `COMMENT` / `CONNECTION` in 11.4.1 and the introduction of engine-defined options `REMOTE_SERVER`, `REMOTE_DATABASE`, and `REMOTE_TABLE` in 10.8.1 and further options in 11.3.1

ES Additional Behavior (ODBC)

ODBC connection strings are used by Spider in Enterprise Server to create connections via ODBC drivers.

The source of the ODBC connection string could be:

- `COMMENT` clause
- `CONNECTION` clause
- engine-defined options
- Foreign server options

These values are combined and converted into a format that is compatible with ODBC.

Connection Methods

CREATE SERVER with COMMENT or CONNECTION

Since earlier versions, connection information can be specified by creating a foreign server, then referencing it in the Spider table definition using `COMMENT=` or `CONNECTION=`.

```
CREATE SERVER s
  FOREIGN DATA WRAPPER mysql
  OPTIONS (HOST 'remote_host', PORT 3306, DATABASE 'db_name',
           USER 'user', PASSWORD 'secret');

CREATE TABLE t (id INT) ENGINE=SPIDER COMMENT='srv "s"';
```

The same server can also be referenced at the partition level.

```
CREATE TABLE t (id INT) ENGINE=SPIDER COMMENT='srv "s"'
PARTITION BY RANGE (a) (
    PARTITION p1 VALUES LESS THAN (3),
    PARTITION p2 VALUES LESS THAN MAXVALUE COMMENT='srv "s_2_2"'
```

Engine-defined options: `REMOTE_SERVER`, `REMOTE_DATABASE`, `REMOTE_TABLE` (Since 10.8.1)

Since MariaDB 10.8.1 (MDEV-27106), engine-defined table options can be used to directly specify connection details:

```
CREATE TABLE t (id INT) ENGINE=SPIDER
  REMOTE_SERVER='s'
  REMOTE_DATABASE='db_name'
  REMOTE_TABLE='remote_t';
```

These engine-defined options override `COMMENT=` when both are present. These options are more structured and are the recommended method for new configurations.

Extended Engine-defined options (Since 11.3.1)

Since MariaDB 11.3.1 (MDEV-28856), more engine-defined options are available. `COMMENT=` and `CONNECTION=` are ignored if there are any engine-defined options and warnings may be generated. Set `spider_suppress_comment_ignored_warning = 1` to suppress the warning that is generated when they are ignored.

COMMENT and CONNECTION Deprecated (Since 11.4.1)

Since MariaDB 11.4.1 (MDEV-28861), the Spider connection information specified by `COMMENT=` and `CONNECTION=` has been deprecated. Instead, use the engine-defined parameters.

ODBC Connection String via CONNECTION (Since 11.4.3-1 ES)

In the following instances, `CONNECTION=` is used directly as the ODBC connection string since MariaDB Enterprise Server 11.4.3-1(MENT-2070):

- `COMMENT=` / `CONNECTION=` are explicitly ignored (i.e., engine-defined options are present, per MDEV-28856)
- The value of `CONNECTION=` follows the ODBC connection string format (`param1=val1;param2=val2;...`)

In previous ES versions, the chosen `COMMENT=`, `CONNECTION=`, and `OPTIONS` fields were used to create the ODBC connection string. See MENT-2076 comment for a complete list of fields used.

CREATE SERVER with FOREIGN DATA WRAPPER ODBC

Foreign server options are directly translated to ODBC connection key-value pairs when using `CREATE SERVER` with `FOREIGN DATA WRAPPER ODBC` (MENT-796). The above-described precedence order is maintained.

```
CREATE SERVER s
  FOREIGN DATA WRAPPER odbc
  OPTIONS (DSN 'MyDSN', UID 'user', PWD 'secret');
```

Supported FOREIGN DATA WRAPPER Values

`CREATE SERVER ... FOREIGN DATA WRAPPER` supports the following wrapper types:

Wrapper Value	Description	Availability
`mysql`	Connects to a remote MySQL server natively	CS + ES
`mariadb`	Connects to a remote MariaDB server natively	CS + ES
`odbc`	Connects to a remote server via ODBC	ES only

Note: The `odbc` wrapper value is only available in MariaDB Enterprise Server (ES). It is not supported in Community Server (CS).

Default Behavior When Connection Information is not Specified

If connection information is not explicitly specified using engine-defined options, Spider can depend on the configuration provided by other methods, such as `COMMENT`, `CONNECTION`, or `CREATE SERVER` statements.

The MariaDB version and configuration method determine the exact resolution behavior. The default behavior when no connection information is provided is currently being reviewed. To ensure predictable behavior, it is advised to explicitly specify connection details using engine-defined options (such as `REMOTE_SERVER`, `REMOTE_DATABASE`, and `REMOTE_TABLE`).

Spider System Variables

The following variables are available when the Spider storage engine has been installed.

See Server System Variables for a complete list of system variables and instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

> **Warning:**
>
> As of MariaDB 13.0, the following Spider table parameters can no longer be set through a table's `COMMENT` or `CONNECTION` string (in either their short or full form): `buffer_size` (`bfz`), `bka_table_name_type` (`btt`), `crd_mode` (`cmd`), `crd_type` (`ctp`), `crd_weight` (`cwg`), `init_sql_alloc_size` (`isa`), `internal_limit` (`ilm`), `internal_offset` (`ios`), `sts_mode` (`smd`), `semi_table_lock` (`stl`), and `semi_table_lock_connection` (`stc`). They were deprecated in earlier releases and have no corresponding table option; set the matching system variable below (for example, `spider_crd_mode`) instead.

MariaDB starting with 10.5.22

Starting from MariaDB 10.5.22, MariaDB 10.6.15, MariaDB 10.9.8, MariaDB 10.10.6, MariaDB 10.11.5, MariaDB 11.0.3, all spider system variables with the value -1 for deferring to table parameter values follow the correct overriding mechanism: table parameter (if set) overrides system variables (if not -1) overrides actual variable default. As a side effect, all such system variables in all versions have the same default value as the table param default value.
Before this change, a non-minus-one system variable value would override the table parameter value. That is, if both the system variable value and the table parameter value were set to be non-minus-one, the system variable value would prevail. For MariaDB 10.7+ where the system variable default values were the same as table param default instead of -1, this means that if the system variable were not set, but a table param is set to a non-default value, the default would override the non-default value.

`spider_auto_increment_mode`

- Description: The auto increment mode.
  - `-1` Falls back to the default value, if the table parameter is not set.

    - `0` Normal Mode. Uses a counter that Spider gets from the remote backend server with an exclusive lock for the auto-increment value. This mode is slow. Use Quick Mode (`2`), if you use Spider tables with the table partitioning feature and the auto-increment column is the first column of the index.
    - `1` Quick Mode. Uses an internal Spider counter for the auto-increment value. This mode is fast, but it is possible for duplicates to occur when updating the same table from multiple Spider proxies.
    - `2` Set Zero Mode. The auto-increment value is given by the remote backend. Sets the column to `0` , even if you set the value to the auto-increment column in your statement. If you use the table with the table partitioning feature, it sets to zero after choosing an inserted partition.
    - `3` When the auto-increment column is set to `NULL` , the value is given by the remote backend server. If you set the auto-increment column to `0` ,the value is given by the local server. Set spider_reset_auto_increment to `2` or `3` if you want to use an auto-increment column on the remote server.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `3`
- DSN Parameter Name: `aim`

`spider_bgs_first_read`

- Description: Number of first read records to use when performing a concurrent background search. To start a range scan on the remote backend, the storage engine first needs to send the first record. Fetching a second record in the same query can save a network round trip stopping the plan if the backend has a single record. The first and second reads are used to warm up for background search. When not using spider_split_read and spider_semi_split_read, the third read fetches the remaining data source in a single fetch.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Records are usually retrieved.
    - `1` and greater: Number of records.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `2`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `bfr`

`spider_bgs_mode`

- Description: Background search mode. This enables the use of a thread per data server connection if the query is not shard-based and must be distributed across shards. The partitioning plugin scans partitions one after the other to optimize memory usage. Because the shards are external, reading all shards can be performed in parallel when the plan prunes multiple partitions.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Disables background search.
    - `1` Uses background search when searching without locks
    - `2` Uses background search when searching without locks or with shared locks.
    - `3` Uses background search regardless of locks.

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `3`
- DSN Parameter Name: `bmd`

`spider_bgs_second_read`

- Description: Number of second read records on the backend server when using background search. When the first records are found from spider_bgs_first_read, the engine continues scanning a range adding a `LIMIT` of spider_bgs_first_read and spider_bgs_second_read.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Records are usually retrieved.
  - `1` and greater: Number of records.
- Scope: Global, Session
- Dynamic: Yes
- Default Session Value: `100`
- Default Table Value: `100`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `bsr`

`spider_bka_engine`

- Description: Storage engine used with temporary tables when the spider_bka_mode system variable is set to `1`. Defaults to the value of the table parameter, which is MEMORY by default.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Session Value: `""`
- Default Table Value: `Memory`
- DSN Parameter Name: `bke`

`spider_bka_mode`

- Description: Internal action to perform when multi-split reads are disabled. If the spider_multi_split_read system variable is set to `0`, Spider uses this variable to determine how to handle statements when the optimizer resolves range retrieval to multiple conditions.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Uses “union all”.
  - `1` Uses a temporary table, if it is judged acceptable.
  - `2` Uses a temporary table, if it is judged acceptable and avoids replication delay.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`

- Range: `-1` to `2`
- DSN Parameter Name: `bkm`

`spider_bka_table_name_type`

- Description: The type of temporary table name for bka.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`

`spider_block_size`

- Description: Size of memory block used in MariaDB. Can usually be left unchanged.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `16384`
- Range: `0` to `4294967295`
- DSN Parameter Name: `bsz`

`spider_buffer_size`

- Description: Buffer size. `-1`, the default, will use the table parameter.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `16000`
- Default Table Value: `16000`
- Range: `-1` to `2147483647`
- Introduced: MariaDB 10.5.4

`spider_bulk_size`

- Description: Size in bytes of the buffer when multiple grouping multiple `INSERT` statements in a batch, (that is, bulk inserts).
  - `-1` The table parameter is adopted.
  - `0` or greater: Size of the buffer.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `16000`
- Default Table Value: `16000`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `bsz`

`spider_bulk_update_mode`

- Description: Bulk update and delete mode. Note: If you use a non-default value for the spider_bgs_mode or spider_split_read system variables, Spider sets this variable to `2`.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Sends `UPDATE` and `DELETE` statements one by one.
  - `1` Collects multiple `UPDATE` and `DELETE` statements, then sends the collected statements one by one.
  - `2` Collects multiple `UPDATE` and `DELETE` statements and sends them together.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `2`
- DSN Parameter Name: `bum`

`spider_bulk_update_size`

- Description: Size in bytes for `UPDATE` and `DELETE` queries when generating bulk updates.
  - `-1` The table parameter is adopted.
  - `0` or greater: Size of buffer.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `16000`
- Default Table Value: `16000`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `bus`

`spider_casual_read`

- Description: Casual Reads enables all isolation levels, (such as repeatable reads) to work with transactions on multiple backends. With auto-commit queries, you can relax read consistency and run on multiple connections to the backends. This enables parallel queries across partitions, even if multiple shards are stored on the same physical server. Deprecated in MariaDB 11.5 due to the complexity of the code for little benefit.
  - `-1` Use table parameter.
  - `0` Use casual read.
  - `1` Choose connection channel automatically.
  - `2` to `63` Number of connection channels.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `63`
- DSN Parameter Name: `##`
- Deprecated: MariaDB 11.5

`spider_conn_recycle_mode`

- Description: Connection recycle mode.
  - `0` Disconnect.
  - `1` Recycle by all sessions.
  - `2` Recycle in the same session.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Range: `0` to `2`
- Default Session Value: `0`

`spider_conn_recycle_strict`

- Description: Whether to force the creation of new connections.
  - `1` Don't force.
  - `0` Force new connection
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Range: `0` to `1`

`spider_conn_wait_timeout`

- Description: Max waiting time in seconds for Spider to get a remote connection.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `10`
- Range: `0` to `1000`
- Introduced: MariaDB 10.3.3

`spider_connect_error_interval`

- Description: Return same error code until interval passes if connection is failed
- Scope: Global,
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `4294967295`

`spider_connect_mutex`

- Description: Whether to serialize remote servers connections (use mutex at connecting). Use this parameter if you get an error or slowdown due to too many connection processes.
  - `0` Not serialized.
  - `1` : Serialized.
- Scope: Global, Session

- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `0`

`spider_connect_retry_count`

- Description: Number of times to retry connections that fail due to too many connection processes.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2` (>= MariaDB 11.8), `1000` (<= MariaDB 11.7)
- Range: `0` to `2147483647`

`spider_connect_retry_interval`

- Description: Interval in microseconds for connection failure due to too many connection processes.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1000`
- Range: `-1` to `9223372036854775807`

`spider_connect_timeout`

- Description: Timeout in seconds to declare remote backend unresponsive when opening a connection. Change for high-latency networks.
  - `-1` The table parameter is adopted.
  - `0` Less than 1.
  - `1` and greater: Number of seconds.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `6`
- Default Table Value: `0`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `cto`

`spider_crd_bg_mode`

- Description: Indexes cardinality statistics in the background. Disable when the spider_crd_mode system variable is set to `3` or when the spider_crd_interval variable is set to `0`.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Disables background confirmation.
  - `2` Enables background confirmation.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `1`

- Range: `-1` to `2`
- DSN Parameter Name: `cbm`

`spider_crd_interval`

- Description: Time interval in seconds of index cardinality statistics. Set to `0` to always get the latest information from remote servers.
  - `-1` The table parameter is adopted.
  - `1` or more: Interval in seconds table state confirmation.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `51`
- Default Table Value: `51`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `civ`

`spider_crd_mode`

- Description: Mode for index cardinality statistics. By default, uses `SHOW` at the table-level.
  - `-1,0` Uses the table parameter.
  - `1` Uses the `SHOW` command.
  - `2` Uses the Information Schema.
  - `3` Uses the `EXPLAIN` command.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `3`
- DSN Parameter Name: `cmd` (`COMMENT`/`CONNECTION`-string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_crd_sync`

- Description: Synchronize index cardinality statistics in partitioned tables.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Disables synchronization.
  - `1` Uses table state synchronization when opening a table, but afterwards performs no synchronization.
  - `2` Enables synchronization.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `2`
- DSN Parameter Name: `csy`

`spider_crd_type`

- Description: Type of cardinality calculation. Only effective when the spider_crd_mode system variable is set to use `SHOW` (`1`) or to use the Information Schema (`2`).
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Uses the value of the spider_crd_weight system variable, as a fixed value.
  - `1` Uses the value of the spider_crd_weight system variable, as an addition value.
  - `2` Uses the value of the spider_crd_weight system variable, as a multiplication value.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `2`
- Range: `-1` to `2`
- DSN Parameter Name: `ctp` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_crd_weight`

- Description: Weight coefficient used to calculate effectiveness of index from the cardinality of column. For more information, see the description for the spider_crd_type system variable.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` or greater: Weight.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `2`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `cwg` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_delete_all_rows_type`

- Description: The type of delete_all_rows.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`

`spider_direct_dup_insert`

- Description: Manages duplicate key check for REPLACE, INSERT IGNORE and LOAD DATA LOCAL INFILE to remote servers. This can save on network roundtrips if the key always maps to a single partition. For bulk operations, records are checked for duplicate key errors one by one on the remote server, unless you set it to avoid duplicate checks on local servers (`1`).
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Performs duplicate checks on the local server.

    - `1` Avoids duplicate checks on the local server.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `ddi`

`spider_direct_order_limit`

- Description: Pushes `ORDER BY` and `LIMIT` operations to the remote server.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Uses local execution.
    - `1` Uses push down execution.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `9223372036854775807`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `dol`

`spider_disable_group_by_handler`

- Description: Whether to disable the spider group by handler, which if created takes over the query execution after query optimization is done.
    - `OFF` Does not disable the spider group by handler.
    - `ON` Disables the spider group by handler.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 10.10.7

`spider_dry_access`

- Description: Simulates an empty result-set. No queries are sent to the backend. Use for performance tuning.
    - `0` Normal access.
    - `1` All access from Spider to data node is suppressed.
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Value: `OFF`

`spider_error_read_mode`

- Description: Sends an empty result-set when reading a backend server raises an error. Useful with applications that don't implement transaction replays.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Returns an error.
  - `1` Returns an empty result.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `erm`

`spider_error_write_mode`

- Description: Sends an empty result-set when writing to a backend server raises an error. Useful with applications that don't implement transaction replays.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Returns an error.
  - `1` Returns an empty result-set on error.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `ewm`

`spider_first_read`

- Description: Number of first read records to start a range scan on the backend server. Spider needs to send the first record. Fetching the second record saves network round-trips, stopping the plan if the backend has a single record. First read and second read are used to warm up for background searches, third reads without using the spider_split_read and spider_semi_split_read system variables fetches the remaining data source in a single last fetch.
  - `-1` Use the table parameter.
  - `0` Usually retrieves records.
  - `1` and greater: Sets the number of first read records.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `2`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `frd`

`spider_force_commit`

- Description: Behavior when error occurs on `XA PREPARE`, `XA COMMIT`, and `XA ROLLBACK` statements.
  - `0` Returns the error.
  - `1` Returns the error when the `xid` doesn't exist, otherwise it continues processing the XA transaction.
  - `2` Continues processing the XA transaction, disregarding all errors.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Range: `0` to `2`

`spider_general_log`

- Description: Whether Spider logs all commands to the General Log. Spider logs error codes according to the spider_log_result_errors system variable.
  - `OFF` Logs no commands.
  - `ON` Logs commands to the General Log.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`

`spider_ignore_comments`

- Description: Whether to unconditionally ignore COMMENT and CONNECTION strings without checking whether table options are specified.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 11.3.0

`spider_index_hint_pushdown`

- Description: Whether to use pushdown index hints, like `force_index`.
  - `0` Do not use pushdown hints
  - `1` Use pushdown hints
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`
- Introduced: MariaDB 10.3.3

`spider_init_sql_alloc_size`

- Description: Initial size of the local SQL buffer.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` or greater: Size of the buffer.

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1024`
- Default Table Value: `1024`
- DSN Parameter Name: `isa` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Range: `-1` to `2147483647`
- Deprecated: MariaDB 10.7.5, MariaDB 10.8.4, MariaDB 10.9.2

`spider_internal_limit`

- Description: Limits the number of records when acquired from a remote server.
  - `-1` The table parameter is adopted.
  - `0` or greater: Records limit.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `9223372036854775807`
- Default Table Value: `9223372036854775807`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `ilm` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_internal_offset`

- Description: Skip records when acquired from the remote server.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` or more : Number of records to skip.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `ios` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_internal_optimize`

- Description: Whether to perform push down operations for OPTIMIZE TABLE statements.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Transmitted.
  - `1` Not transmitted.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`

- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `iom`

`spider_internal_optimize_local`

- Description: Whether to transmit to remote servers when OPTIMIZE TABLE statements are executed on the local server.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Not transmitted.
  - `1` Transmitted.
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `iol`

`spider_internal_sql_log_off`

- Description: Whether to log SQL statements sent to the remote server in the General Query Log.
  - Explicitly setting this system variable to either `ON` or `OFF` causes the Spider node to send a `SET sql_log_off` statement to each of the data nodes using the `SUPER` privilege.
  - `-1` Don't know or does not matter; don't send 'SET SQL_LOG_OFF' statement
  - `0` Send 'SET SQL_LOG_OFF 0' statement to data nodes (logs SQL statements to the remote server)
  - `1` Send 'SET SQL_LOG_OFF 1' statement to data nodes (doesn't log SQL statements to the remote server)
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric` (previously `boolean`)
- Range: `-1` to `1`
- Default Session Value: `-1` (previously `ON`)

`spider_internal_unlock`

- Description: Whether to transmit unlock tables to the connection of the table used with `SELECT` statements.
  - `0` Not transmitted.
  - `1` Transmitted.
- Data Type: `boolean`
- Default Session Value: `0`

`spider_internal_xa`

- Description: Whether to implement XA at the server- or storage engine-level. When using the server-level, set different values for the server_id system variable on all server instances to generate different `xid` values.
  - `OFF` Uses the storage engine protocol.
  - `ON` Uses the server protocol.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`

`spider_internal_xa_id_type`

- Description: The type of internal_xa id.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Range: `-1` to `1`

`spider_internal_xa_snapshot`

- Description: Limitation for reading consistent data on all backend servers when using MariaDB's internal XA implementation and `START TRANSACTION WITH CONSISTENT SNAPSHOT`.
  - `0` Raise error when using a Spider table.
  - `1` Raise error when issued a `START TRANSACTION` statement.
  - `2` Takes a consistent snapshot on each backend, but loses global consistency.
  - `3` Starts transactions with XA, but removes `CONSISTENT SNAPSHOT`.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Range: `0` to `3`
- Default Session Value: `0`

`spider_load_crd_at_startup`

- Description: Whether to load CRD from the system table at startup.
  - `-1` Use table parameter
  - `0` Do not load
  - `1` Load
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`
- Introduced: MariaDB 10.3.3
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_load_sts_at_startup`

- Description: Whether to load STS from the system table at startup.
  - `-1` Use table parameter
  - `0` Do not load
  - `1` Load
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `1`
- Range: `-1` to `1`

- Introduced: MariaDB 10.3.3
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_local_lock_table`

- Description: Whether to push LOCK TABLES statements down to the remote server.
  - `0` Transmitted.
  - `1` Not transmitted.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`spider_lock_exchange`

- Description:
  Whether to convert SELECT… LOCK IN SHARE MODE and SELECT… FOR UPDATE statements into a LOCK TABLE statement.
  - `0` Not converted.
  - `1` Converted.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `0`

`spider_log_result_error_with_sql`

- Description: How to log SQL statements with result errors.
  - `0` No log
  - `1` Log error
  - `2` Log warning summary
  - `3` Log warning
  - `4` Log info (Added in MariaDB 10.5.4)
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4`

`spider_log_result_errors`

- Description: Log results from data nodes to the Spider node in the Error Log. Performs no logging by default.
  - `0` : Logs no errors from data nodes.
  - `1` : Logs errors from data nodes.
  - `2` : Logs errors from data nodes, as well as warning summaries.
  - `3` : Logs errors from data nodes, as well as warning summaries and details.
  - `4` : Logs errors from data nodes, as well as warning summaries and details, and result summaries.
- Scope: Global

- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `4`

`spider_low_mem_read`

- Description: Whether to use low memory mode when executing queries issued internally to remote servers that return result-sets.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Doesn't use low memory mode.
  - `1` Uses low memory mode.
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `1`

`spider_max_connections`

- Description: Maximum number of connections from Spider to a remote MariaDB servers. Defaults to `0`, which is no limit.
- Command-line: `--spider-max-connections`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Range: `0` to `99999`
- Introduced: MariaDB 10.3.3

`spider_max_order`

- Description: Maximum number of columns for `ORDER BY` operations.
  - `-1` The table parameter is adopted.
  - `0` and greater: Maximum number of columns.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `32767`
- Default Table Value: `32767`
- Range: `-1` to `32767`
- DSN Parameter Name: `mod`

`spider_multi_split_read`

- Description:
  Whether to divide a statement into multiple SQL statements sent to the remote backend server when the optimizer resolves range retrievals to multiple conditions.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Doesn't divide statements.

    - `1` Divides statements.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `100`
- Default Table Value: `100`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `msr`

`spider_net_read_timeout`

- Description: TCP timeout in seconds to declare remote backend servers unresponsive when reading from a connection. Change for high latency networks.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Less than 1 second timeout.
    - `1` and greater: Timeout in seconds.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `600`
- Default Table Value: `600`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `nrt`

`spider_net_write_timeout`

- Description: TCP timeout in seconds to declare remote backend servers unresponsive when writing to a connection. Change for high latency networks.
    - `-1` The table parameter is adopted.
    - `0` Less than 1 second timeout.
    - `1` and more: Timeout in seconds.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `600`
- Default Table Value: `600`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `nwt`

`spider_ping_interval_at_trx_start`

- Description: Resets the connection with keepalive timeout in seconds by sending a ping.
    - `0` At every transaction.
    - `1` and greater: Number of seconds.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`

- Default Value: `3600`
- Range: `0` to `2147483647`

`spider_quick_mode`

- Description: Sets the backend query buffering to cache on the remote backend server or in the local buffer.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Local buffering, it acquires records collectively with `store_result`.
  - `1` Remote buffering, it acquires records one by one. Interrupts don't wait and recovery on context switch back.
  - `2` Remote buffering, it acquires records one by one. Interrupts wait to the end of the acquisition.
  - `3` Local buffering, uses a temporary table on disk when the result-set is greater than the value of the spider_quick_page_size system variable.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `3`
- Default Table Value: `3`
- Range: `-1` to `3`
- DSN Parameter Name: `qmd`

`spider_quick_page_byte`

- Description: Memory limit by size in bytes in a page when acquired record by record.
  - `-1` The table parameter is used. When quick_mode is 1 or 2, Spider stores at least 1 record even if quick_page_byte is smaller than 1 record. When quick_mode is 3, quick_page_byte is used for judging using temporary tables. That is given priority when spider_quick_page_byte is set.
  - `0` or greater: Memory limit.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `10485760`
- Range: `-1` to `9223372036854775807`
- Introduced: MariaDB 10.4.3, MariaDB 10.3.13

`spider_quick_page_size`

- Description: Number of records in a page when acquired record by record.
  - `-1` The table parameter is adopted.
  - `0` or greater: Number of records.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1024` (>=MariaDB 10.7), `-1` (<= MariaDB 10.6)
- Default Table Value: `100`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `qps`

`spider_read_only_mode`

- Description: Whether to allow writes on Spider tables.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Allows writes to Spider tables.
  - `1` Makes tables read- only.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0` (>=MariaDB 10.7), `-1` (<= MariaDB 10.6)
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `rom`

`spider_remote_access_charset`

- Description: Forces the specified session character set when connecting to the backend server. This can improve connection time performance.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Session Value: `null`

`spider_remote_autocommit`

- Description: Sets the auto-commit mode when connecting to backend servers. This can improve connection time performance.
  - `-1` Doesn't change the auto-commit mode.
  - `0` Sets the auto-commit mode to `0`.
  - `1` Sets the auto-commit mode to `1`.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `-1`
- Range: `-1` to `1`

`spider_remote_default_database`

- Description: Sets the local default database when connecting to backend servers. This can improve connection time performance.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `string`
- Default Session Value: Empty string

`spider_remote_sql_log_off`

- Description: Sets the sql_log_off system variable to use when connecting to backend servers.
  - `-1` Doesn't set the value.
  - `0` Doesn't log Spider SQL statements to remote backend servers.

    - `1` Logs SQL statements on remote backend
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `-1`
- Range: `-1` to `1`

`spider_remote_time_zone`

- Description: Forces the specified time zone setting when connecting to backend servers. This can improve connection performance when you know the time zone.
- Scope: Global
- Dynamic: Yes
- Data Type: `string`
- Default Session Value: `null`

`spider_remote_trx_isolation`

- Description: Sets the Transaction Isolation Level when connecting to the backend server.
    - `-1` Doesn't set the Isolation Level.
    - `0` Sets to the `READ UNCOMMITTED` level.
    - `1` Sets to the `READ COMMITTED` level.
    - `2` Sets to the `REPEATABLE READ` level.
    - `3` Sets to the `SERIALIZABLE` level.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `-1`
- Range: `-1` to `3`

`spider_remote_wait_timeout`

- Description: Wait timeout in seconds on remote server. `-1` means not set.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `-1`
- Range: `-1` to `2147483647`
- Introduced: MariaDB 10.4.5

`spider_reset_sql_alloc`

- Description: Resets the per connection SQL buffer after an SQL statement executes.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Doesn't reset.
    - `1` Resets.
- Scope: Global, Session
- Dynamic: Yes

- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `1`
- DSN Parameter Name: `rsa`

`spider_same_server_link`

- Description: Enables the linking of a table to the same local instance.
  - `0` Disables linking.
  - `1` Enables linking.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`

`spider_second_read`

- Description: Number of second read records on the backend server when the first records are found from the first read. Spider continues scanning a range, adding a `LIMIT` using the spider_first_read and spider_second_read variables.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Usually retrieves records.
  - `1` and greater: Number of records.
- Scope: Global, Session
- Dynamic: Yes
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `srd`

`spider_select_column_mode`

- Description: Mode for column retrieval from remote backend server.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Uses index columns when the `SELECT` statement can resolve with an index, otherwise uses all columns.
  - `1` Uses all columns judged necessary to resolve the query.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `1`
- DSN Parameter Name: `scm`

`spider_selupd_lock_mode`

- Description: Local lock mode on `INSERT SELECT`.
  - `-1` Falls back to the default value, if the table parameter is not set.

    - `0` Takes no locks.
    - `1` Takes shared locks.
    - `2` Takes exclusive locks.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `2`
- DSN Parameter Name: `slm#`

`spider_semi_split_read`

- Description:
  Whether to use chunk retrieval with offset and limit parameters on SQL statements sent to the remote backend server when using the spider_split_read system variable.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Doesn't use chunk retrieval.
    - `1 or more` Uses chunk retrieval.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Default Table Value: `2`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `ssr#`

`spider_semi_split_read_limit`

- Description: Sets the limit value for the spider_semi_split_read system variable.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` or more: The limit value.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `9223372036854775807`
- Default Table Value: `9223372036854775807`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `ssl#`

`spider_semi_table_lock`

- Description: Enables semi-table locking. This adds a LOCK TABLES statement to SQL executions sent to the remote backend server when using non-transactional storage engines to preserve consistency between roundtrips.
    - `0` Disables semi-table locking.
    - `1` Enables semi-table locking.

- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0` (>=MariaDB 10.8), `1` (<= MariaDB 10.7)
- Range: `0` to `1`
- DSN Parameter Name: `stl#`

`spider_semi_table_lock_connection`

- Description: Whether to use multiple connections with semi-table locking. To enable semi-table locking, use the spider_semi_table_lock system variable.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Uses the same connection.
  - `1` Uses different connections.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `1`
- DSN Parameter Name: `stc#`

`spider_semi_trx`

- Description: Enables semi-transactions. This controls transaction consistency when an SQL statement is split into multiple statements issued to the backend servers. You can preserve or relax consistency as need. Spider encapsulates auto-committed SQL statements within a transaction on the remote backend server. When using `READ COMMITTED` or `READ UNCOMMITTED` transaction isolation levels to force consistency, set the spider_semi_trx_isolation system variable to `2`.
  - `0` Disables semi-transaction consistency.
  - `1` Enables semi-transaction consistency.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `ON`

`spider_semi_trx_isolation`

- Description: Set consistency during range SQL execution when spider_sync_trx_isolation is 1
  - `-1` OFF
  - `0` READ UNCOMMITTED
  - `1` READ COMMITTED
  - `2` REPEATABLE READ
  - `3` SERIALIZABLE
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `-1`

- Range: `-1` to `3`

`spider_skip_default_condition`

- Description: Whether to compute condition push downs.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Computes condition push downs.
  - `1` Doesn't compute condition push downs.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `1`
- DSN Parameter Name: `sdc`

`spider_skip_parallel_search`

- Description: Whether to skip parallel search by specific conditions.
  - `-1` :use table parameter
  - `0` :not skip
  - `1` :skip parallel search if query is not SELECT statement
  - `2` :skip parallel search if query has SQL_NO_CACHE
  - `3` :1+2
- Command line: `--spider-skip-parallel-search=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Range: `-1` to `3`
- Introduced: MariaDB 10.3.3

`spider_slave_trx_isolation`

- Description: Transaction isolation level when Spider table is used by slave SQL thread.
  - `-1` off
  - `0` read uncommitted
  - `1` read committed
  - `2` repeatable read
  - `3` serializable
- Command line: `--spider-slave-trx-isolation=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `-1`
- Range: `-1` to `3`
- Introduced: MariaDB 10.4.3, MariaDB 10.3.13

`spider_split_read`

- Description: Number of records in chunk to retry the result when a range query is sent to remote backend servers.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` or more: Number of records.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `9223372036854775807`
- Default Table Value: `9223372036854775807`
- Range: `-1` to `9223372036854775807`
- DSN Parameter Name: `srd`

`spider_store_last_crd`

- Description: Whether to store last CRD result in the system table.
  - `-1` Use table parameter.
  - `0` Do not store last CRD result in the system table.
  - `1` Store last CRD result in the system table.
- Command line: `--spider-store-last-crd=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`
- Introduced: MariaDB 10.3.3
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_store_last_sts`

- Description: Whether to store last STS result in the system table.
  - `-1` Use table parameter.
  - `0` Do not store last STS result in the system table.
  - `1` Store last STS result in the system table.
- Command line: `--spider-store-last-sts=#`
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`
- Introduced: MariaDB 10.3.3
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_strict_group_by`

- Description:
  Whether to use columns in select clause strictly for group by clause

    - `-1` Use the table parameter.
    - `0` Do not strictly use columns in select clause for group by clause
    - `1` Use columns in select clause strictly for group by clause
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Range: `-1` to `1`
- Introduced: MariaDB 10.5.4

`spider_sts_bg_mode`

- Description:
  Enables background confirmation for table statistics. When background confirmation is enabled, Spider uses one thread per partition to maintain table status. Disable when the spider_sts_interval system variable is set to `0`, which causes Spider to always retrieve the latest information as need. It is effective, when the spider_sts_interval system variable is set to `10`.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Disables background confirmation.
    - `1` Enables background confirmation (create thread per table/partition).
    - `2` Enables background confirmation (use static threads). (from MariaDB 10.)
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `2`
- Range: `-1` to `2`
- DSN Parameter Name: `sbm`

`spider_sts_interval`

- Description: Time interval of table statistics from the remote backend servers.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Retrieves the latest table statistics on request.
    - `1` or more: Interval in seconds for table state confirmation.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `10`
- Default Table Value: `10`
- Range: `-1` to `2147483647`
- DSN Parameter Name: `siv`

`spider_sts_mode`

- Description: Table statistics mode.
  Mode for table statistics. The SHOW command is used at the table level default.
    - `-1,0` Uses the table parameter.
    - `1` Uses the `SHOW` command.

    - `2` Uses the Information Schema.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `1`
- Default Table Value: `1`
- Range: `-1` to `2`
- DSN Parameter Name: `smd` (`COMMENT` / `CONNECTION` -string parameter removed in MariaDB 13.0)
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

`spider_sts_sync`

- Description: Synchronizes table statistics in partitioned tables.
    - `-1` Falls back to the default value, if the table parameter is not set.
    - `0` Doesn't synchronize table statistics in partitioned tables.
    - `1` Synchronizes table state when opening a table, doesn't synchronize after opening.
    - `2` Synchronizes table statistics.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Session Value: `0`
- Default Table Value: `0`
- Range: `-1` to `2`
- DSN Parameter Name: `ssy`

`spider_support_xa`

- Description: XA Protocol for mirroring and for multi-shard transactions.
    - `1` Enables XA Protocol for these Spider operations.
    - `0` Disables XA Protocol for these Spider operations.
- Scope: Global
- Dynamic: No
- Data Type: `boolean`
- Default Table Value: `1`

`spider_suppress_comment_ignored_warning`

- Description: Whether to suppress warnings that table COMMENT or CONNECTION strings are ignored due to specified table options.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`
- Introduced: MariaDB 11.3.0

`spider_sync_autocommit`

- Description: Whether to push down local auto-commits to remote backend servers.

    - `OFF` Pushes down local auto-commits.
    - `ON` Doesn't push down local auto-commits.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `ON`

`spider_sync_sql_mode`

- Description: Whether to sync sql_mode.
    - `OFF` No sync
    - `ON` Sync
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`
- Introduced: MariaDB 10.4.7

`spider_sync_time_zone`

- Description: Whether to push the local time zone down to remote backend servers.
    - `OFF` Doesn't synchronize time zones.
    - `ON` Synchronize time zones.
- Scope: Global
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`
- Removed: MariaDB 10.3.9

`spider_sync_trx_isolation`

- Description: Pushes local transaction isolation levels down to remote backend servers.
    - `OFF` Doesn't push down local isolation levels.
    - `ON` Pushes down local isolation levels.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `ON`

`spider_table_crd_thread_count`

- Description: Static background thread count of table crd.
- Command line: `--spider-table-crd-thread-count=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value:

    - `1` (>= MariaDB 10.4.33, MariaDB 10.5.24, MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3)
    - `10` (<= MariaDB 10.4.32, MariaDB 10.5.23, MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3, MariaDB 11.2.2)
- Range: `1` to `4294967295`
- Deprecated: MariaDB 11.7

`spider_table_init_error_interval`

- Description: Interval in seconds where the same error code is returned if table initialization fails. Use to protect against infinite loops in table links.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `4294967295`

`spider_table_sts_thread_count`

- Description: Static background thread count of table sts.
- Command line: `--spider-table-sts-thread-count=#`
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
    - `1` (>= MariaDB 10.4.33, MariaDB 10.5.24, MariaDB 10.6.17, MariaDB 10.11.7, MariaDB 11.0.5, MariaDB 11.1.4, MariaDB 11.2.3)
    - `10` (<= MariaDB 10.4.32, MariaDB 10.5.23, MariaDB 10.6.16, MariaDB 10.11.6, MariaDB 11.0.4, MariaDB 11.1.3, MariaDB 11.2.2)
- Range: `1` to `4294967295`
- Deprecated: MariaDB 11.7

`spider_udf_ct_bulk_insert_interval`

- Description: Interval in milliseconds between bulk inserts at copying. For use with the UDF spider_copy_tables, which copies table data linked to a Spider table from the source server to destination server using bulk insert. If this interval is 0, it may cause higher write traffic.
    - `-1` Uses the UDF parameter.
    - `0` and more: Time in milliseconds.
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `10`
- Default Table Value: `10`
- Range: `-1` to `2147483647`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_udf_ct_bulk_insert_rows`

- Description: Number of rows to insert at a time when copying during bulk inserts.
  - `-1, 0`: Uses the table parameter.
  - `1` and more: Number of rows
- Scope: Global
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `100`
- Default Table Value: `100`
- Range: `-1` to `9223372036854775807`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_udf_ds_bulk_insert_rows`

- Description: Number of rows inserted at a time during bulk inserts when the result-set is stored in a temporary table on executing a UDF.
  - `-1, 0` Uses the UDF parameter.
  - `1` or more: Number of rows
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `3000`
- Default Table Value: `3000`
- Range: `-1` to `9223372036854775807`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_udf_ds_table_loop_mode`

- Description: Whether to store the result-set in the same temporary table when the temporary table list count for UDF is less than the result-set count on UDF execution.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Drops records.
  - `1` Inserts the last table.
  - `2` Inserts the first table and loops again.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-1` to `2`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_udf_ds_use_real_table`

- Description: Whether to use real table for temporary table list.

    - `-1` Use UDF parameter.
    - `0` Do not use real table.
    - `1` Use real table.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `-1` to `1`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_udf_table_lock_mutex_count`

- Description: Mutex count of table lock for Spider UDFs.
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `20`
- Range: `1` to `4294967295`
- Removed: MariaDB 10.10

`spider_udf_table_mon_mutex_count`

- Description: Mutex count of table mon for Spider UDFs.
- Scope: Global
- Dynamic: No
- Data Type: `numeric`
- Default Value: `20`
- Range: `1` to `4294967295`
- Removed: MariaDB 10.10

`spider_use_all_conns_snapshot`

- Description: Whether to pass `START TRANSACTION WITH SNAPSHOT` statements to all connections.
    - `OFF` Doesn't pass statement to all connections.
    - `ON` Passes statement to all connections.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Session Value: `OFF`

`spider_use_cond_other_than_pk_for_update`

- Description: Whether to use all conditions even if condition has a primary key.
    - `0` Don't use all conditions
    - `1` Use all conditions
- Scope: Global, Session
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `1`
- Introduced: MariaDB 10.3.13, MariaDB 10.4.3

`spider_use_consistent_snapshot`

- Description:
  Whether to push a local `START TRANSACTION WITH CONSISTENT` statement down to remote backend servers.
  - `OFF` Doesn't push the local statement down.
  - `ON` Pushes the local statement down.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`spider_use_default_database`

- Description: Whether to use the default database.
  - `OFF` Doesn't use the default database.
  - `ON` Uses the default database.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `ON`

`spider_use_flash_logs`

- Description: Whether to push FLUSH LOGS statements down to remote backend servers.
  - `OFF` Doesn't push the statement down.
  - `ON` Pushes the statement down.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `boolean`
- Default Value: `OFF`

`spider_use_handler`

- Description: Converts HANDLER SQL statements.
  When the spider_sync_trx_isolation system variable is set to `0`, Spider disables HANDLER conversions to prevent use of the statement on the SERIALIZABLE isolation level.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Converts HANDLER statements into SELECT statements.
  - `1` Passes HANDLER to the remote backend server.
  - `2` Converts SQL statements to HANDLER statements.
  - `3` Converts SQL statements to HANDLER statements and HANDLER statements to SQL statements.
- Scope: Global, Session
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `0`
- Default Table Value: `0`
- Range: `-1` to `3`
- DSN Parameter Name: `uhd`
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3
- Removed: MariaDB 10.10

`spider_use_pushdown_udf`

- Description:
  When using a UDF function in a condition and the engine_condition_pushdown system variable is set to `1`, whether to execute the UDF function locally or push it down.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Doesn't transmit the UDF
  - `1` Transmits the UDF.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `-1`
- Default Table Value: `1`
- Range: `-1` to `1`
- DSN Parameter Name: `upu`

`spider_use_snapshot_with_flush_tables`

- Description:
  Whether to encapsulate FLUSH LOGS and UNLOCK TABLES statements when `START TRANSACTION WITH CONSISTENT` and `FLUSH TABLE WITH READ LOCK` statements are sent to the remote backend servers.
  - `0` : No encapsulation.
  - `1` : Encapsulates, only when the spider_use_all_conns_snapshot system variable i set to `1`.
  - `2` :
    Synchronizes the snapshot using a LOCK TABLES statement and [flush|FLUSH TABLES]] at the XA transaction level. This is only effective when the spider_use_all_cons_snapshot system variable is set to `1`.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `0`
- Range: `0` to `2`

`spider_use_table_charset`

- Description: Whether to use the local table character set for the remote backend server connections.
  - `-1` Falls back to the default value, if the table parameter is not set.
  - `0` Use `utf8`.
  - `1` Uses the table character set.
- Scope: Global, Session
- Dynamic: Yes

- Data Type: `numeric`
- Default Value: `1`
- Default Table Value: `1`
- Range: `-1` to `1`
- DSN Parameter Name: `utc`

`spider_version`

- Description: The current Spider version. Removed in MariaDB 10.9.2 when the Spider version number was matched with the server version.
- Scope: Global
- Dynamic: No
- Data Type: `string`
- Removed: MariaDB 10.9.2

`spider_wait_timeout`

- Description: Wait timeout in seconds of setting to remote server. `-1` means not set.
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `604800`
- Range: `-1` to `2147483647`
- Introduced: MariaDB 10.4.5

`spider_xa_register_mode`

- Description: Mode of XA transaction register into system table.
  - `0` Register all XA transactions
  - `1` Register only write XA transactions
- Command-line: `--spider-xa-register-mode=#`
- Scope: Global, Session
- Dynamic: Yes
- Data Type: `numeric`
- Default Value: `1`
- Range: `0` to `1`
- Introduced: MariaDB 10.3.3
- Deprecated: MariaDB 10.7.4, MariaDB 10.8.3

Spider Table Parameters

When a table uses the Spider storage engine, the following Spider table parameters can be set in the `COMMENT` clause of the CREATE TABLE statement. Many Spider table parameters have corresponding system variables, so they can be set for all Spider tables on the node. For additional information, see the Spider System Variables page.

From MariaDB 11.3, many table parameters can be set using dedicated Spider table options, see the Table Option Name fields below. From MariaDB 11.4, using the `COMMENT` clause is deprecated, as well as table parameters that do not have corresponding table options.

`access_balances`

- Description: Connection load balancing integer weight.
- Default Table Value: `0`
- DSN Parameter Name: `abl`
- Deprecated: MariaDB 11.4.0

`active_link_count`

- Description: Number of active remote servers, for use in load balancing read connections
- Default Table Value: `all backends`
- DSN Parameter Name: `alc`
- Deprecated: MariaDB 11.4.0

`auto_increment_mode`

- Description: The table level value of spider_auto_increment_mode
- Table Option Name: `AUTO_INCREMENT_MODE`
- Table Option Introduced: MariaDB 11.3.0

`bgs_mode`

- Description: The table level value of spider_bgs_mode.
- Table Option Name: `BGS_MODE`
- Table Option Introduced: MariaDB 11.3.0

`bulk_size`

- Description: The table level value of spider_bulk_size.
- Table Option Name: `BULK_SIZE`
- Table Option Introduced: MariaDB 11.3.0

`bulk_update_size`

- Description: The table level value of spider_bulk_update_size.
- Table Option Name: `BULK_UPDATE_SIZE`
- Table Option Introduced: MariaDB 11.3.0

`casual_read`

- Description:
- Default Table Value:
- DSN Parameter Name:
- Introduced: Spider 3.2
- Deprecated: MariaDB 11.4.0

`connect_timeout`

- Description: The table level value of spider_connect_timeout.
- Table Option Name: `CONNECT_TIMEOUT`
- Table Option Introduced: MariaDB 11.3.0

`database`

- Description: Database name for reference table that exists on remote backend server.
- Default Table Value: `local table database`
- DSN Parameter Name: `database`
- Table Option Name: `REMOTE_DATABASE`
- Table Option Introduced: MariaDB 10.8.0

`default_file`

- Description: Configuration file used when connecting to remote servers. When the default_group table variable is set, this variable defaults to the values of the `--defaults-extra-file` or `--defaults-file` options. When the default_group table variable is not set, it defaults to `none`.
- Default Table Value: `none`
- DSN Parameter Name: `dff`
- Table Option Name: `DEFAULT_FILE`
- Table Option Introduced: MariaDB 11.3.0

`default_group`

- Description: Group name in configuration file used when connecting to remote servers.
- Default Table Value: `none`
- DSN Parameter Name: `dfg`
- Table Option Name: `DEFAULT_GROUP`
- Table Option Introduced: MariaDB 11.3.0

`delete_all_rows_type`

- Description: The table level value of spider_delete_all_rows_type.
- Introduced: Spider 3.2
- Table Option Name: `DELETE_ALL_ROWS_TYPE`
- Table Option Introduced: MariaDB 11.3.0

`force_bulk_delete`

- Description:
- Introduced: MariaDB 10.0.5
- Table Option Name: `FORCE_BULK_DELETE`
- Table Option Introduced: MariaDB 11.3.0

`force_bulk_update`

- Description:
- Introduced: MariaDB 10.0.5
- Table Option Name: `FORCE_BULK_UPDATE`
- Table Option Introduced: MariaDB 11.3.0

`host`

- Description: Host name of remote server.
- Default Table Value: `localhost`
- DSN Parameter Name: `host`

- Table Option Name: `REMOTE_HOST`
- Table Option Introduced: MariaDB 11.3.0

`idx000`

- Description: When using an index on Spider tables for searching, Spider uses this hint to search the remote table. The remote table index is related to the Spider table index by this hint. The number represented by `000` is the index ID, which is the number of the index shown by the SHOW CREATE TABLE statement. `000` is the Primary Key. For instance, `idx000 "force index(PRIMARY)"` (in abbreviated format `idx000 "f PRIMARY"`).
  - `f` force index
  - `u` use index
  - `ig` ignore index
- Default Table Value: `none`
- Table Option Name: `IDX`
- Table Option Introduced: MariaDB 11.3.0

`link_status`

- Description: Change status of the remote backend server link.
  - `0` Doesn't change status.
  - `1` Changes status to `OK`.
  - `2` Changes status to `RECOVERY`.
  - `3` Changes status to no more in group communication.
- Default Table Value: `0`
- DSN Parameter Name: `lst`
- Deprecated: MariaDB 11.4.0

`monitoring_bg_interval`

- Description: Interval of background monitoring in microseconds.
- Default Table Value: `10000000`
- DSN Parameter Name: `mbi`
- Deprecated: MariaDB 11.4.0

`monitoring_bg_kind`

- Description: Kind of background monitoring to use.
  - `0` Disables background monitoring.
  - `1` Monitors connection state.
  - `2` Monitors state of table without `WHERE` clause.
  - `3` Monitors state of table with `WHERE` clause (currently unsupported).
- Default Table Value: `0`
- DSN Parameter Name: `mbk`
- Deprecated: MariaDB 11.4.0

`monitoring_kind`

- Description: Kind of monitoring.
  - `0` Disables monitoring
  - `1` Monitors connection state.

    - `2` Monitors state of table without `WHERE` clause.
    - `3` Monitors state of table with `WHERE` clause (currently unsupported).
- Default Table Value: `0`
- DSN Parameter Name: `mkd`
- Deprecated: MariaDB 11.4.0

`monitoring_limit`

- Description: Limits the number of records in the monitoring table. This is only effective when Spider monitors the state of a table, which occurs when the monitoring_kind table variable is set to a value greater than `1`.
- Default Table Value: `1`
- Range: `0` upwards
- DSN Parameter Name: `mlt`
- Deprecated: MariaDB 11.4.0

`monitoring_server_id`

- Description: Preferred monitoring `@@server_id` for each backend failure. You can use this to geo-localize backend servers and set the first Spider monitoring node to contact for failover. In the event that this monitor fails, other monitoring nodes are contacted. For multiple copy backends, you can set a lazy configuration with a single MSI instead of one per backend.
- Default Table Value: `server_id`
- DSN Parameter Name: `msi`
- Deprecated: MariaDB 11.4.0

`multi_split_read`

- Description: The table level value of spider_multi_split_read.
- Table Option Name: `MULTI_SPLIT_READ`
- Table Option Introduced: MariaDB 11.3.0

`net_read_timeout`

- Description: The table level value of spider_net_read_timeout.
- Table Option Name: `NET_READ_TIMEOUT`
- Table Option Introduced: MariaDB 11.3.0

`net_write_timeout`

- Description: The table level value of spider_net_write_timeout.
- Table Option Name: `NET_WRITE_TIMEOUT`
- Table Option Introduced: MariaDB 11.3.0

`password`

- Description: Remote server password.
- Default Table Value: `none`
- DSN Parameter Name: `password`
- Table Option Name: `REMOTE_PASSWORD`
- Table Option Introduced: MariaDB 11.3.0

`port`

- Description: Remote server port.
- Default Table Value: `3306`
- DSN Parameter Name: `port`
- Table Option Name: `REMOTE_PORT`
- Table Option Introduced: MariaDB 11.3.0

`priority`

- Description: Priority. Used to define the order of execution. For instance, Spider uses priority when deciding the order in which to lock tables on a remote server.
- Default Table Value: `1000000`
- DSN Parameter Name: `prt`
- Table Option Name: `PRIORITY`
- Table Option Introduced: MariaDB 11.3.0

`query_cache`

- Description: Uses the option for the Query Cache when issuing SELECT statements to the remote server.
  - `0` No option used.
  - `1` Uses the SQL_CACHE option.
  - `2` Uses the SQL_NO_CACHE option.
- Default Table Value: `0`
- DSN Parameter Name: `qch`
- Table Option Name: `QUERY_CACHE`
- Table Option Introduced: MariaDB 11.3.0

`query_cache_sync`

- Description: A two-bit bitmap. Whether to pass the option for the Query Cache (if any) when issuing SELECT statements to the remote server.
  - `0` No option passed.
  - `1` Passes the SQL_CACHE option, if specified in the query to the spider table.
  - `2` Passes the SQL_NO_CACHE option, if specified in the query to the spider table.
  - `3` Passes both the SQL_CACHE option and the SQL_NO_CACHE option, if specified in the query to the spider table.
- Default Table Value: `3`
- Table Option Name: `QUERY_CACHE_SYNC`
- Table Option Introduced: MariaDB 11.3.0

`read_rate`

- Description: Rate used to calculate the amount of time Spider requires when executing index scans.
- Default Table Value: `0.0002`
- DSN Parameter Name: `rrt`
- Deprecated: MariaDB 11.4.0

`scan_rate`

- Description: Rate used to calculate the amount of time Spider requires when scanning tables.

- Default Table Value: `0.0001`
- DSN Parameter Name: `srt`
- Deprecated: MariaDB 11.4.0

`server`

- Description: Server name. Used when generating connection information with CREATE SERVER statements.
- Default Table Value: `none`
- DSN Parameter Name: `srv`
- Table Option Name: `REMOTE_SERVER`
- Table Option Introduced: MariaDB 10.8.0

`skip_parallel_search`

- Description: The table level value of spider_skip_parallel_search.
- Table Option Name: `SKIP_PARALLEL_SEARCH`
- Table Option Introduced: MariaDB 11.3.0

`socket`

- Description: Remote server socket.
- Default Table Value: `none`
- DSN Parameter Name: `socket`
- Table Option Name: `REMOTE_SOCKET`
- Table Option Introduced: MariaDB 11.3.0

`ssl_ca`

- Description: Path to the Certificate Authority file.
- Default Table Value: `none`
- DSN Parameter Name: `sca`
- Table Option Name: `SSL_CA`
- Table Option Introduced: MariaDB 11.3.0

`ssl_capath`

- Description: Path to directory containing trusted TLS CA certificates in PEM format.
- Default Table Value: `none`
- DSN Parameter Name: `scp`
- Table Option Name: `SSL_CAPATH`
- Table Option Introduced: MariaDB 11.3.0

`ssl_cert`

- Description: Path to the certificate file.
- Default Table Value: `none`
- DSN Parameter Name: `scr`
- Table Option Name: `SSL_CERT`
- Table Option Introduced: MariaDB 11.3.0

`ssl_cipher`

- Description: List of allowed ciphers to use with TLS encryption.
- Default Table Value: `none`
- DSN Parameter Name: `sch`
- Table Option Name: `SSL_CIPHER`
- Table Option Introduced: MariaDB 11.3.0

`ssl_key`

- Description: Path to the key file.
- Default Table Value: `none`
- DSN Parameter Name: `sky`
- Table Option Name: `SSL_KEY`
- Table Option Introduced: MariaDB 11.3.0

`ssl_verify_server_cert`

- Description: Enables verification of the server's Common Name value in the certificate against the host name used when connecting to the server.
  - `0` Disables verification.
  - `1` Enables verification.
- Default Table Value: `0`
- DSN Parameter Name: `svc`
- Table Option Name: `SSL_VSC`
- Table Option Introduced: MariaDB 11.3.0

`table`

- Description: Destination table name.
- Default Table Value: `Same table name`
- DSN Parameter Name: `tbl`
- Table Option Name: `REMOTE_TABLE`
- Table Option Introduced: MariaDB 10.8.0

`table_count_mode`

- Description: for setting table flags HA_STATS_RECORDS_IS_EXACT and HA_HAS_RECORDS.
- Default Table Value: `0`
- Table Option Name: `TABLE_COUNT_MODE`
- Table Option Introduced: MariaDB 11.3.0

`username`

- Description: user name for the data node.
- Default Table Value: `Same user name`
- Table Option Name: `REMOTE_USERNAME`
- Table Option Introduced: MariaDB 11.3.0

`use_pushdown_udf`

- Description: The table level value of spider_use_pushdown_udf.

- Table Option Name: `USE_PUSHDOWN_UDF`
- Table Option Introduced: MariaDB 11.3.0

`wrapper`

- Description: wrapper for the data node.
- Table Option Name: `WRAPPER`
- Table Option Introduced: MariaDB 11.3.0

Spider Table: Connection Parameters

The Spider table's connection to a remote server is managed via the following engine-defined settings. The `CREATE TABLE` statement specifies these parameters, which take precedence over `COMMENT=` and `CONNECTION=`. See Specifying Connection Information for Spider Tables for a detailed explanation of all connection methods and precedence rules.

Engine-defined Connection Options

Option	Description	Available since
`REMOTE_SERVER`	Name of the server object generated with `CREATE SERVER` that will be used for the remote connection.	10.8.1
`REMOTE_DATABASE`	Database name on the remote server. The value defined in the referenced server object is used if it is not provided.	10.8.1
`REMOTE_TABLE`	Name of the table on the remote server. The local table name is used if it is not provided.	10.8.1

> **Note:**
>
> Starting with version 11.3.1, `COMMENT=` and `CONNECTION=` are silently ignored whenever any engine-defined option is present.

> **Note:**
>
> To suppress the warning, `set spider_suppress_comment_ignored_warning = 1`. Since 11.4.1, the connection methods `COMMENT=` and `CONNECTION=` have been deprecated. Instead, make use of engine-defined options.

Spider Functions

See SPIDER_BG_DIRECT_SQL.

This UDF allows you to execute SQL statements on remote data nodes in the background, enabling concurrent processing and non-blocking operations.

See SPIDER_COPY_TABLES.

Learn how to use this function to copy table data from one Spider link ID to another, useful for migrating data or rebalancing shards without stopping the service.

See SPIDER_DIRECT_SQL.

This function executes an SQL string directly on a specified remote backend server, allowing for maintenance tasks or queries that bypass local parsing.

See SPIDER_FLUSH_TABLE_MON_CACHE.

Use this UDF to refresh the cache used by Spider's monitoring threads, ensuring that the status of remote tables and connections is up to date.

This page is licensed: CC BY-SA / Gnu FDL

SPIDER_BG_DIRECT_SQL

Syntax

```
SPIDER_BG_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

Description

Executes the given SQL statement in the background on the remote server, as defined in the parameters listing. If the query returns a result-set, it sttores the results in the given temporary table. When the given SQL statement executes successfully, this function returns the number of called UDF's. It returns `0` when the given SQL statement fails.

This function is a UDF installed with the Spider storage engine.

Examples

```
SELECT SPIDER_BG_DIRECT_SQL('SELECT * FROM example_table',  '',
   'srv "node1", port "8607"') AS "Direct Query";
+--------------+
| Direct Query |
+--------------+
|            1 |
+--------------+
```

Parameters

`error_rw_mode`

- Description: Returns empty results on network error.
  - `0` : Return error on getting network error.
  - `1`: Return 0 records on getting network error.
- Default Table Value: `0`
- DSN Parameter Name: `erwm`

SPIDER_COPY_TABLES

Syntax

```
SPIDER_COPY_TABLES(spider_table_name,
  source_link_id, destination_link_id_list [,parameters])
```

Description

A UDF installed with the Spider Storage Engine, this function copies table data from `source_link_id` to `destination_link_id_list`. The service does not need to be stopped in order to copy.

If the Spider table is partitioned, the name must be of the format `table_name#P#partition_name`. The partition name can be viewed in the `mysql.spider_tables` table, for example:

```
SELECT table_name FROM mysql.spider_tables;
+-------------+
| table_name  |
+-------------+
| spt_a#P#pt1 |
| spt_a#P#pt2 |
| spt_a#P#pt3 |
+-------------+
```

Returns `1` if the data was copied successfully, or `0` if copying the data failed.

This page is licensed: CC BY-SA / Gnu FDL

SPIDER_DIRECT_SQL

Syntax

```
SPIDER_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

Description

A UDF installed with the Spider Storage Engine, this function is used to execute the SQL string `sql` on the remote server, as defined in `parameters`. If any resultsets are returned, they are stored in the `tmp_table_list`.

The function returns `1` if the SQL executes successfully, or `0` if it fails.

Examples

```
SELECT SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"');
+---------------------------------------------------------------------------+
| SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"') |
+---------------------------------------------------------------------------+
|                                                                         1 |
+---------------------------------------------------------------------------+
```

SPIDER_FLUSH_TABLE_MON_CACHE

Syntax

```
SPIDER_FLUSH_TABLE_MON_CACHE()
```

Description

A UDF installed with the Spider Storage Engine, this function is used for refreshing monitoring server information. It returns a value of `1`.

Examples

```
SELECT SPIDER_FLUSH_TABLE_MON_CACHE();
+--------------------------------+
| SPIDER_FLUSH_TABLE_MON_CACHE() |
+--------------------------------+
|                              1 |
+--------------------------------+
```

Spider FAQ

What does “[ERROR] mysqld: Can’t find record in ‘spider_tables’” mean?

This happens when you have a Spider table defined that does not point to an existing table on a data node.

Are there minimum Spider settings?

```
myisam-recover=FORCE,BACKUP
```

What does “select spider_ping_table()” in the general log mean?

This is used by Spider monitoring to ask other monitoring nodes the status of a table.

Do I need a primary key on physical tables?

Not having a primary key will generate errors for resynchronizing tables via spider_copy_table().

Can I use Spider on top of Galera shards?

Yes, XA transactions can be disabled from Spider. Until Galera 4.0 fully supports xa transactions, spider can point to a maxscale proxy that can manage transparent node election in case of failure inside a shard group. Note that disabling XA will break cross shard WRITES in case of transaction ROLLBACK.
This architecture need to be used with care if you have a highly transactional workload that can generate cross shard deadlocks.

What are the most used architectures for Spider HA?

- Delegation of shard node replication using asynchronous replication and slave election with GTID.
- Delegation of shard node replication via active passive HA solutions.
- Shard builds via replication into Spider tables is interesting when you can route READS to a pool of Spider nodes reattaching the shards.

What are the most used architectures for Spider Map Reduce?

- Map reduce in Spider is limited to a single table. Building spider on top of some views can eliminate the need to use joins.
- Replication to universal tables to every shard is commonly used to enable the views on each shard.

What about Grants on shards?

- When using MRR and BKA (and you do so with network storage), when Spider needs to create temporary tables on the backends, use the CREATE TEMPORARY TABLES privilege. Spider can still switch to a lower performance solution using spider_bka_mode=2, or Query push down or range predicate using spider_bka_mode=0

VIDEX Storage Engine

> **Note:**
>
> VIDEX is a community contribution to MariaDB Server, developed and maintained by ByteDance. This storage engine is available from MariaDB 12.3.

This document explains how to install and use **VIDEX** with MariaDB, including:

- Installing/enabling the **VIDEX plugin** in MariaDB.
- Running the **VIDEX-Server** (statistics service) as a container.
- Running a one-shot **videx-sync** workflow to build a VIDEX database.
- Comparing `EXPLAIN` between your original schema and the VIDEX schema.

The VIDEX server repository, with more examples and extension points, can be accessed here. It contains an example dataset (TPC-H tiny).

Prerequisites

- A running MariaDB server you can connect to (the *target*).
- A MariaDB build that includes the `VIDEX` engine plugin (the *MariaDB-VIDEX*).
  - For a quick start, the *target* MariaDB and *MariaDB-VIDEX* can be the same instance.
- Docker (to run `VIDEX-Server` and `videx-sync`).

What is VIDEX

VIDEX is a **virtual/hypothetical index engine** for what-if analysis.

- **Goal**: Evaluate how potential indexes (and optimizer decisions such as join orders) would change query plans *without creating real indexes on production data*.
- **How it works**: VIDEX replays optimizer / handler calls using **statistics** (cardinality, NDV, histograms, etc.) instead of reading table data. Complex statistics computation is offloaded to an external service (**VIDEX-Server**) via HTTP.

In practice, you keep your existing MariaDB schema and data as the *target*, and create a second schema whose tables use `ENGINE=VIDEX`. You then run `EXPLAIN` on both schemas and compare plans.

> **Note:**
>
> Research note (AI4DB)
>
> Estimating **multi-column joint NDV (Number of Distinct Value)** and **cardinality** is a challenging research problem. You can extend VIDEX by implementing your own estimation models in **VIDEX-Server** to improve accuracy for your workload.

Components and Roles

VIDEX typically involves the following roles:

- **Target MariaDB**: your original database instance and schema (contains real data).
- **MariaDB with VIDEX plugin** (*MariaDB-VIDEX*): a MariaDB instance that has the `VIDEX` storage engine plugin enabled.
  - It can be the *same* instance as the *target MariaDB* (common for a quick start).
  - Alternatively, it can be a separate MariaDB instance used only for what-if analysis.
- **VIDEX-Server**: a standalone HTTP service that stores metadata/statistics and answers estimation requests from the VIDEX plugin.

This document focuses on a **docker-based workflow** for `VIDEX-Server` and `videx-sync`, so users can complete the VIDEX end-to-end flow with a few `docker` commands, while the MariaDB server itself is managed by users.

Prepare Sample Data

You can test VIDEX with the `TPC-H tiny` sample.

1. Download `tpch_tiny.sql.tar.gz` from here.
2. Create a database, and import the data (replace `<TARGET_HOST>`, `<TARGET_PORT>`, etc. with your settings:

```
mariadb -h<TARGET_HOST> -P<TARGET_PORT> -u<TARGET_USER> -p<TARGET_PASS> \
  -e "CREATE DATABASE tpch_tiny;"

tar -zxf tpch_tiny.sql.tar.gz
mariadb -h<TARGET_HOST> -P<TARGET_PORT> -u<TARGET_USER> -p<TARGET_PASS> \
  -Dtpch_tiny < tpch_tiny.sql
```

Install and Enable the VIDEX Plugin

Connect to your MariaDB instance and check whether the `VIDEX` engine is available:

```
SHOW ENGINES
```

If you see a row for `VIDEX` with `SUPPORT` as `YES` or `DEFAULT`, the engine is available.

Install and Run VIDEX-Server in Docker

`VIDEX-Server` is a separate service providing statistics/estimation over HTTP, and *MariaDB-VIDEX* calls it to get statistics information for generating query plans.

Images

Public images are on Docker Hub: `kangrongme/videx-server:0.2.0`

Start the Server

Expose container port `5001`:

```
docker run -d --name videx-server \
  -p 5001:5001 \
  kangrongme/videx-server:0.2.0
```

When done, the service is reachable under `http://<YOUR_HOST_IP>:5001`.

> **Note:**
>
> Reachability note
>
> Prefer using a **routable IP address** (your host/server IP) instead of `localhost/127.0.0.1`. This matters because both MariaDB-VIDEX (the plugin) and `videx-sync` need to reach `VIDEX-Server`. If any of them run inside a container, `localhost/127.0.0.1` refers to that container itself (not your host), so the service isn't reachable via `localhost`.

Build the VIDEX Schema

The `VIDEX-Server` image supports two entry point modes:

- `server` (default): start `VIDEX-Server`
- `sync`: run a one-shot workflow to collect metadata from `--target`, then:
  - add metadata to `VIDEX-Server`

- create virtual tables in `--videx`

Command Template

```
docker run --rm --name videx-sync \
  kangrongme/videx-server:0.2.0 sync \
  --target <TARGET_HOST>:<TARGET_PORT>:<TARGET_DB>:<TARGET_USER>:<TARGET_PASS> \
  [--videx <VIDEX_HOST>:<VIDEX_PORT>:<VIDEX_DB>:<VIDEX_USER>:<VIDEX_PASS>] \
  [--videx_server <VIDEX_SERVER_HOST>:<VIDEX_SERVER_PORT>]
```

Notes:

1. If `--videx` is not specified, a default database `videx_{TARGET_DB}` is created in `--target`.
2. If you run a separate MariaDB-VIDEX instance, pass that instance as `--videx`.
3. If your `VIDEX-Server` is not `<TARGET_HOST>:5001`, pass `--videx_server` explicitly.

Localhost Failures

Inside a container, `localhost/127.0.0.1` refers to the container itself.

On Linux Docker Engine, you can reach the host via `host.docker.internal` using `--add-host`:

```
docker run --rm --name videx-sync \
  --add-host=host.docker.internal:host-gateway \
  kangrongme/videx-server:0.2.0 sync \
  --target host.docker.internal:<PORT>:<DB>:<USER>:<PASS> \
  --videx host.docker.internal:<PORT>:<VIDEX_DB>:<VIDEX_USER>:<VIDEX_PASS> \
  --videx_server host.docker.internal:<VIDEX_SERVER_PORT>
```

However, if *MariaDB-VIDEX* itself is also running in a container, reachability can become tricky. Using a routable IP is the most robust approach.

Configure the Plugin

On MariaDB, the VIDEX plugin exposes **session** system variables.

```
SHOW VARIABLES LIKE '%videx_server_ip%';
```

Example output:

```
+-----------------+----------------+
| Variable_name   | Value          |
+-----------------+----------------+
| videx_server_ip | 127.0.0.1:5001 |
+-----------------+----------------+
```

- `videx_server_ip`: **critical**. This is the address (`host:port`) that *MariaDB-VIDEX* uses to call `VIDEX-Server`.

Configure them for your current session before running `EXPLAIN` on `ENGINE=VIDEX` tables (replace `<VIDEX_SERVER_HOST>:<VIDEX_SERVER_PORT>` with your settings):

```
SET SESSION videx_server_ip = '<VIDEX_SERVER_HOST>:<VIDEX_SERVER_PORT>';
```

Quickstart

This section assumes:

- Users already have **one MariaDB instance** running.
- Users want to create the VIDEX schema **in the same instance** (which means “MariaDB-VIDEX == Target MariaDB”).

- MariaDB is running and reachable.
- The routable IP is something like `203.0.113.42` (example only).
- MariaDB is reachable at, for instance, `203.0.113.42:15508` (example only).
- `VIDEX-Server` is reachable at, for instance, `203.0.113.42:5001` (example only).
- The default user/password credentials are: `videx` / `password`.

Step 1

Start VIDEX-Server

```
docker run -d --name videx-server \
  -p 5001:5001 \
  kangrongme/videx-server:0.2.0
```

Step 2

Build VIDEX schema via videx-sync

```
docker run --rm --name videx-sync \
  kangrongme/videx-server:0.2.0 sync \
  --target 203.0.113.42:15508:tpch_tiny:videx:password \
  --videx  203.0.113.42:15508:videx_tpch_tiny:videx:password \
  --videx_server 203.0.113.42:5001
```

Step 3

Run EXPLAIN on the original schema

Run `EXPLAIN` on your original tables:

```
USE tpch_tiny;
SET SESSION use_stat_tables = NEVER;
EXPLAIN SELECT s_name, count(*) AS numwait FROM supplier, lineitem l1, orders, nation WHERE s_suppkey =
l1.l_suppkey AND o_orderkey = l1.l_orderkey AND o_orderstatus = 'F' AND l1.l_receiptdate >
l1.l_commitdate AND EXISTS (SELECT * FROM lineitem l2 WHERE l2.l_orderkey = l1.l_orderkey AND
l2.l_suppkey <> l1.l_suppkey) AND NOT EXISTS (SELECT * FROM lineitem l3 WHERE l3.l_orderkey =
l1.l_orderkey AND l3.l_suppkey <> l1.l_suppkey AND l3.l_receiptdate > l3.l_commitdate) AND s_nationkey
= n_nationkey AND n_name = 'IRAQ' GROUP BY s_name ORDER BY numwait DESC, s_name;
```

> **Note:**
>
> Collecting histograms may change MariaDB's cardinality estimates (for instance, histogram-based estimates rather than InnoDB index statistics). Since VIDEX aims to simulate InnoDB index engine behavior, users can set `SET SESSION use_stat_tables = NEVER;` to make `EXPLAIN` results more similar between InnoDB and the VIDEX engine.

The `EXPLAIN` output for the original schema is:

```
+----+--------------------+----------+--------+-------------------------------------------------------
+--------------+---------+--------------------------------+-------+-----------------------------------
----------+
| id | select_type        | table    | type   | possible_keys                                         |
key          | key_len | ref                            | rows  | Extra
|
+----+--------------------+----------+--------+-------------------------------------------------------
+--------------+---------+--------------------------------+-------+-----------------------------------
----------+
| 1  | PRIMARY            | orders   | ALL    | PRIMARY                                               |
<null>       | <null>  | <null>                         | 14944 | Using where; Using temporary; Using
filesort |
| 1  | PRIMARY            | l1       | ref    | LINEITEM_UK1,LINEITEM_FK1                             |
LINEITEM_FK1 | 4       | tpch_tiny.orders.O_ORDERKEY    | 1     | Using where
|
| 1  | PRIMARY            | supplier | eq_ref | PRIMARY,SUPPLIER_FK1,idx_S_NATIONKEY_S_SUPPKEY_S_NAME |
PRIMARY      | 4       | tpch_tiny.l1.L_SUPPKEY         | 1     |
|
| 1  | PRIMARY            | nation   | eq_ref | PRIMARY                                               |
PRIMARY      | 4       | tpch_tiny.supplier.S_NATIONKEY | 1     | Using where
|
| 1  | PRIMARY            | l2       | ref    | LINEITEM_UK1,LINEITEM_FK1                             |
LINEITEM_FK1 | 4       | tpch_tiny.orders.O_ORDERKEY    | 1     | Using where; FirstMatch(nation)
|
| 3  | DEPENDENT SUBQUERY | l3       | ref    | LINEITEM_UK1,LINEITEM_FK1                             |
LINEITEM_UK1 | 4       | tpch_tiny.l1.L_ORDERKEY        | 1     | Using where
|
+----+--------------------+----------+--------+-------------------------------------------------------
+--------------+---------+--------------------------------+-------+-----------------------------------
----------+
```

Step 4

Run EXPLAIN on the VIDEX schema

Run `EXPLAIN` on the VIDEX schema (tables are `ENGINE=VIDEX`):

```
USE videx_tpch_tiny;
SET SESSION videx_server_ip = '203.0.113.42:5001';
EXPLAIN SELECT s_name, count(*) AS numwait FROM supplier, lineitem l1, orders, nation WHERE s_suppkey =
l1.l_suppkey AND o_orderkey = l1.l_orderkey AND o_orderstatus = 'F' AND l1.l_receiptdate >
l1.l_commitdate AND EXISTS (SELECT * FROM lineitem l2 WHERE l2.l_orderkey = l1.l_orderkey AND
l2.l_suppkey <> l1.l_suppkey) AND NOT EXISTS (SELECT * FROM lineitem l3 WHERE l3.l_orderkey =
l1.l_orderkey AND l3.l_suppkey <> l1.l_suppkey AND l3.l_receiptdate > l3.l_commitdate) AND s_nationkey
= n_nationkey AND n_name = 'IRAQ' GROUP BY s_name ORDER BY numwait DESC, s_name;
```

The `EXPLAIN` output for the VIDEX schema is:

```
+----+--------------------+----------+--------+-----------------------------------------------------
+--------------+---------+--------------------------------------+-------+-----------------------------
----------------+
| id | select_type        | table    | type   | possible_keys                                       |
key          | key_len | ref                                  | rows  | Extra
|
+----+--------------------+----------+--------+-----------------------------------------------------
+--------------+---------+--------------------------------------+-------+-----------------------------
----------------+
| 1  | PRIMARY            | orders   | ALL    | PRIMARY                                             |
<null>       | <null>  | <null>                               | 14883 | Using where; Using temporary;
Using filesort |
| 1  | PRIMARY            | l1       | ref    | LINEITEM_UK1,LINEITEM_FK1                           |
LINEITEM_FK1 | 4       | videx_tpch_tiny.orders.O_ORDERKEY    | 1     | Using where
|
| 1  | PRIMARY            | supplier | eq_ref | PRIMARY,SUPPLIER_FK1,idx_S_NATIONKEY_S_SUPPKEY_S_NAME |
PRIMARY      | 4       | videx_tpch_tiny.l1.L_SUPPKEY         | 1     |
|
| 1  | PRIMARY            | nation   | eq_ref | PRIMARY                                             |
PRIMARY      | 4       | videx_tpch_tiny.supplier.S_NATIONKEY | 1     | Using where
|
| 1  | PRIMARY            | l2       | ref    | LINEITEM_UK1,LINEITEM_FK1                           |
LINEITEM_FK1 | 4       | videx_tpch_tiny.orders.O_ORDERKEY    | 1     | Using where; FirstMatch(nation)
|
| 3  | DEPENDENT SUBQUERY | l3       | ref    | LINEITEM_UK1,LINEITEM_FK1                           |
LINEITEM_UK1 | 4       | videx_tpch_tiny.l1.L_ORDERKEY        | 1     | Using where
|
+----+--------------------+----------+--------+-----------------------------------------------------
+--------------+---------+--------------------------------------+-------+-----------------------------
----------------+
```

Compare the output between Step 3 and Step 4.

Notes and Best Practices

1. `videx-sync` can be time-consuming on large schemas, because it needs to collect metadata/statistics. The metadata collection method is extensible; the VIDEX source repository also discusses lighter-weight sampling approaches.
2. Networking matters. Since `VIDEX-Server` is often in a container, `localhost/127.0.0.1` may not refer to what you expect. The routable IP is recommended for reachability, as it ensures that both *MariaDB-VIDEX* and the container can reach it.

Converting Tables from MyISAM to InnoDB

The task

You have decided to change one or more tables from MyISAM to InnoDB. That should be as simple as `ALTER TABLE foo ENGINE=InnoDB`. But you have heard that there might be some subtle issues.

This describes possible issues that may arise and what to do about them.

Recommendation. One way to assist in searching for issues in is to do (at least in *nix)

```
mysqldump --no-data --all-databases >schemas
egrep 'CREATE|PRIMARY' schemas   # Focusing on PRIMARY KEYs
egrep 'CREATE|FULLTEXT' schemas  # Looking for FULLTEXT indexes
egrep 'CREATE|KEY' schemas       # Looking for various combinations of indexes
```

Understanding how the indexes work will help you better understand what might run faster or slower in InnoDB.

INDEX Issues

(Most of these Recommendations and some of these Facts have exceptions.)

Fact. Every InnoDB table has a PRIMARY KEY. If you do not provide one, then the first non-NULL UNIQUE key is used. If that can't be done, then a 6-byte, hidden, integer is provided.

Recommendation. Look for tables without a PRIMARY KEY. Explicitly specify a PRIMARY KEY, even if it's an artificial AUTO_INCREMENT. This is not an absolute requirement, but it is a stronger admonishment for InnoDB than for MyISAM. Some day you may need to walk through the table; without an explicit PK, you can't do it.

Fact. The fields of the PRIMARY KEY are included in each Secondary key.

- Check for redundant indexes with this in mind.

```
PRIMARY KEY(id),
INDEX(b), -- effectively the same as INDEX(b, id)
INDEX(b, id) -- effectively the same as INDEX(b)
```

- (Keep one of the INDEXes, not both)
- Note subtle things like

```
PRIMARY KEY(id),
UNIQUE(b), -- keep for uniqueness constraint
INDEX(b, id) -- DROP this one
```

- Also, since the PK and the data coexist:

```
PRIMARY KEY(id),
INDEX(id, b) -- DROP this one; it adds almost nothing
```

Contrast. This feature of MyISAM is not available in InnoDB; the value of 'id' will start over at 1 for each different value of 'abc':

```
id INT UNSIGNED NOT NULL AUTO_INCREMENT,
PRIMARY KEY (abc, id)
```

A way to simulate the MyISAM 'feature' might be something like: What you want is this, but it won't work because it is referencing the table twice:

```
INSERT INTO foo
    (other, id, ...)
    VALUES
    (123, (SELECT MAX(id)+1 FROM foo WHERE other = 123), ...);
```

Instead, you need some variant on this. (You may already have a BEGIN…COMMIT.)

```
BEGIN;
SELECT @id := MAX(id)+1 FROM foo WHERE other = 123 FOR UPDATE;
INSERT INTO foo
    (other, id, ...)
    VALUES
    (123, @id, ...);
COMMIT;
```

Having a transaction is mandatory to prevent another thread from grabbing the same id.

Recommendation. Look for such PRIMARY KEYs. If you find such, ponder how to change the design. There is no straightforward workaround. However, the following may be ok. (Be sure that the datatype for id is big enough since it won't start over.):

```
id INT UNSIGNED NOT NULL AUTO_INCREMENT,
PRIMARY KEY (abc, id),
UNIQUE(id)
```

Recommendation. Keep the PRIMARY KEY short. If you have Secondary keys, remember that they include the fields of the PK. A long PK would make the
Secondary keys bulky. Well, maybe not — if the is a lot of overlap in fields. Example: `PRIMARY KEY(a,b,c), INDEX(c,b,a)`
— no extra bulk.

Recommendation. Check AUTO_INCREMENT sizes.

- BIGINT is almost never needed. It wastes at least 4 bytes per row (versus INT).
- Always use UNSIGNED and NOT NULL.
- MEDIUMINT UNSIGNED (16M max) might suffice instead of INT
- Be sure to be pessimistic — it is painful to ALTER.

Contrast. "Vertical Partitioning". This is where you artificially split a table to move bulky columns (eg, a BLOB) into another, parallel, table. It is beneficial in MyISAM to avoid stepping over the blob when you don't need to read it. InnoDB stores BLOB and TEXT differently — 767 bytes are in the record, the rest is in some other block. So, it may (or may not) be worth putting the tables back together. Caution: An InnoDB row is limited to 8KB, and the 767 counts against that.

Fact. FULLTEXT (prior to MariaDB 10.0.5) and SPATIAL indexes are not available in InnoDB. Note that MyISAM and InnoDB FULLTEXT indexes use different stopword lists and different system variables.

Recommendation. Search for such indexes. Keep such tables in MyISAM.
Better yet, do Vertical Partitioning (see above) to split out the minimum number of columns from InnoDB.

Fact. The maximum length of an INDEX is different between the Engines.
(This change is not likely to hit you, but watch out.) MyISAM allows 1000 bytes; InnoDB allows 767 bytes, just big enough for a

```
VARCHAR(255) CHARACTER SET utf8.

ERROR 1071 (42000): Specified key was too long; max key length is 767 bytes
```

Fact. The PRIMARY KEY is included in the data. Hence, SHOW TABLE STATUS will show and `Index_length` of 0 bytes (or 16KB) for a table with no secondary indexes. Otherwise, `Index_length` is the total size for the secondary keys.

Fact. The PRIMARY KEY is included in the data. Hence, exact match by PK may be a little faster with InnoDB. And, "range" scans by PK are likely to be faster.

Fact. A lookup by Secondary Key traverses the secondary key's BTree, grabs the PRIMARY KEY, then traverses the PK's BTree. Hence, secondary key lookups are a little more cumbersome in InnoDB.

Contrast. The fields of the PRIMARY KEY are included in each Secondary key. This may lead to "Using index" (in the EXPLAIN plan) for InnoDB for cases where it did not happen in MyISAM. (This is a slight performance boost, and counteracts the double-lookup otherwise needed.) However, when "Using index" would be useful on the PRIMARY KEY, MyISAM would do an "index scan", yet InnoDB effectively has to do a "table scan".

Same as MyISAM. Almost always

```
INDEX(a)   -- DROP this one because the other one handles it.
INDEX(a,b)
```

Contrast. The data is stored in PK order. This means that "recent" records are 'clustered' together at the end. This may give you better 'locality of reference' than in MyISAM.

Same as MyISAM. The optimizer almost never uses two indexes in a single SELECT. (5.1 will occasionally do "index merge".) SELECT in subqueries and UNIONs can independently pick indexes.

Subtle issue. When you DELETE a row, the AUTO_INCREMENT id are burned. Ditto for REPLACE, which is a DELETE plus an INSERT.

Very subtle issue. Replication occurs on COMMIT. If you have multiple threads using transactions, the AUTO_INCREMENTs can arrive at a slave out of order. One transaction BEGINs, grabs an id. Then another transaction grabs an id but COMMITs before the first finishes.

Same as MyISAM. "Prefix" indexing is usually bad in both InnoDB and MyISAM. Example: `INDEX(foo(30))`

Non-INDEX Issues

Disk space for InnoDB is likely to be 2-3 times as much as for MyISAM.

MyISAM and InnoDB use RAM radically differently. If you change all your tables, you should make significant adjustments:

- key_buffer_size — small but non-zero; say, 10M;
- innodb_buffer_pool_size — 70% of available RAM

InnoDB has essentially no need for CHECK, OPTIMIZE, or ANALYZE. Remove them from your maintenance scripts. (No real harm if you keep them.)

Backup scripts may need checking. A MyISAM table can be backed up by copying three files. With InnoDB this is only possible if innodb_file_per_table is set to 1. Before MariaDB 10.0, capturing a table or database for copying from production to a development environment was not possible. Change to mysqldump. Since MariaDB 10.0 a hot copy can be created - see Backup and restore overview.

Before MariaDB 5.5, the DATA DIRECTORY table option was not supported for InnoDB. Since MariaDB 5.5 it is supported, but only in CREATE TABLE. INDEX DIRECTORY has no effect, since InnoDB does not use separate files for indexes. To better balance the workload through several disks, the paths of some InnoDB log files can also be changed.

Understand autocommit and BEGIN/COMMIT.

- (default) autocommit = 1: In the absence of any BEGIN or COMMIT statements, every statement is a transaction by itself. This is close to the MyISAM behavior, but is not really the best.
- autocommit = 0: COMMIT will close a transaction and start another one. To me, this is kludgy.
- (recommended) BEGIN…COMMIT gives you control over what sequence of operation(s) are to be considered a transaction and "atomic". Include the
  ROLLBACK statement if you need to undo stuff back to the BEGIN.

Perl's DBIx::DWIW and Java's JDBC have API calls to do BEGIN and COMMIT. These are probably better than 'executing' BEGIN and COMMIT.

Test for errors everywhere! Because InnoDB uses row-level locking, it can stumble into deadlocks that you are not expecting. The engine will automatically ROLLBACK to the BEGIN. The normal recovery is to redo, beginning at the BEGIN. Note that this is a strong reason to have BEGINs.

LOCK/UNLOCK TABLES — remove them. Replace them (sort of) with BEGIN … COMMIT. (LOCK will work if innodb_table_locks is set to 1, but it is less efficient, and may have subtle issues.)

In 5.1, ALTER ONLINE TABLE can speed up some operations significantly.
(Normally ALTER TABLE copies the table over and rebuilds the indexes.)

The "limits" on virtually everything are different between MyISAM and InnoDB.
Unless you have huge tables, wide rows, lots of indexes, etc, you are unlikely to stumble into a different limit.

Mixture of MyISAM and InnoDB? This is OK. But there are caveats.

- RAM settings should be adjusted to accordingly.
- JOINing tables of different Engines works.
- A transaction that affects tables of both types can ROLLBACK InnoDB changes, but will leave MyISAM changes intact.
- Replication: MyISAM statements are replicated when finished; InnoDB statements are held until the COMMIT.

FIXED (vs DYNAMIC) is meaningless in InnoDB.

PARTITION — You can partition MyISAM and InnoDB tables. Remember the screwball rule: You must either

- have no UNIQUE (or PRIMARY) keys, or
- have the value you are "partitioning on" in every UNIQUE key.

The former is not advised for InnoDB. The latter is messy if you want an
AUTO_INCREMENT.

PRIMARY KEY in PARTITION — Since every key must include the field on which you are PARTITIONing, how can AUTO_INCREMENT work?
Well, there seems to be a convenient special case:

- This works: PRIMARY KEY(autoinc, partition_key)
- This does not work for InnoDB: PRIMARY KEY(partition_key, autoinc)

That is, an AUTO_INCREMENT will correctly increment, and be unique across all
PARTITINOs, when it is the first field of the PRIMARY KEY, but not otherwise.

Machine Learning with MindsDB

> **Note:**
>
> MindsDB is third-party software, not developed or maintained by MariaDB and not included with MariaDB Server. MariaDB doesn't test, validate, or support it. Refer to its own documentation and license terms.

Overview

MindsDB is a third-party application that interfaces with MariaDB Server to provide Machine Learning capabilities through SQL. The interface is done via the Connect Storage Engine.

Installation

To get a functional MariaDB - MindsDB installation, one needs to install the following components:

- MindsDB: follow the instructions in the project's official documentation.
- Connect Storage Engine must be enabled for the integration to work. See installing the connect storage engine.

MindsDB connects to MariaDB Server via a regular user to setup a dedicated database called `mindsdb`. Which user are used is specified within MindsDB's configuration file.

For example, if MindsDB is installed locally, one can create a user called `mindsdb@localhost`. MindsDB only authenticates via the mysql_native_password plugin, hence one must set a password for the user:

```
CREATE USER mindsdb@localhost;
SET PASSWORD FOR mindsdb@localhost=PASSWORD("password");
```

The user must be granted the global FILE privilege and all privileges on the `mindsdb` database.

```
GRANT FILE ON *.* TO mindsdb@localhost;
GRANT ALL ON mindsdb.* TO mindsdb@localhost;
```

Assuming MindsDB is in the python path one can start up MindsDB with the following parameters:

```
python -m mindsdb --config=$CONFIG_PATH --api=http,mysql
```

Make sure `$CONFIG_PATH` points to the appropriate MindsDB configuration file.

Usage

Always consult the project's official documentation for up-to-date usage scenarios as MindsDB is an actively developed project.

For a step-by-step example, you can consult the following blog post.

If the connection between MindsDB and MariaDB is successful, you should see the `mindsdb` database present and two tables within it: `commands` and `predictors`.

MindsDB, as an AutoML framework does all the work when it comes to training the AI model. What is necessary is to pass it the initial data, which MindsDB retrieves via a SELECT statement. This can be done by inserting into the `predictors` table.

```
INSERT INTO `predictors`
       (`name`, `predict`, `select_data_query`)
VALUES ('bikes_model', 'count', 'SELECT * FROM test.bike_data');
```

The values inserted into predictors act as a command instructing MindsDB to:

1. Train a model called ‘bikes_model’
2. From the input data, learn to predict the ‘count’ column.
3. The input data is generated via the select statement ‘SELECT * FROM test.bike_data’.
   The `select_data_query` should be a valid select that MindsDB can run against MariaDB.

FEDERATED Storage Engine

The FEDERATED Storage Engine is a legacy storage engine no longer being supported. A fork, FederatedX is being actively maintained. Since MariaDB 10.0, the CONNECT storage engine also permits accessing a remote database via MySQL or ODBC connection (table types: MYSQL, ODBC).

The FEDERATED Storage Engine was originally designed to let one access data remotely without using clustering or replication, and perform local queries that automatically access the remote data.

See ALTER EVENT.

Learn how to modify the characteristics of an existing event, such as its schedule, body, or enabled status, without dropping and recreating it.

See Event Limitations.

A list of restrictions associated with the Event Scheduler, including the inability to return result sets and specific date range limitations.

This page is licensed: CC BY-SA / Gnu FDL

Events Overview

Events are named database objects containing SQL statements that are to be executed at a later stage, either once off, or at regular intervals.

They function very similarly to the Windows Task Scheduler or Unix cron jobs.

Creating, modifying or deleting events requires the EVENT privilege.

Creating Events

Events are created with the CREATE EVENT statement.

Example

```
CREATE EVENT test_event
  ON SCHEDULE EVERY 1 MINUTE DO
   UPDATE test.t1 SET a = a + 1;
```

Executing Events

Events are only executed if the event scheduler is running. This is determined by the value of the event_scheduler system variable, which needs to be set to `On` for the event scheduler to be running.

You can check if the Event scheduler is running with:

```
SHOW PROCESSLIST;
+----+-----------------+-----------+------+---------+------+-----------------------------+---------------
---+----------+
| Id | User            | Host      | db   | Command | Time | State                       | Info
| Progress |
+----+-----------------+-----------+------+---------+------+-----------------------------+---------------
---+----------+
| 40 | root            | localhost | test | Sleep   | 4687 |                             | NULL
|    0.000 |
| 41 | root            | localhost | test | Query   |    0 | init                        | SHOW
PROCESSLIST |    0.000 |
| 42 | event_scheduler | localhost | NULL | Daemon  |   30 | Waiting for next activation | NULL
|    0.000 |
+----+-----------------+-----------+------+---------+------+-----------------------------+---------------
---+----------+
```

If the event scheduler is not running and `event_scheduler` has been set to `OFF`, use:

```
SET GLOBAL event_scheduler = ON;
```

to activate it. If `event_scheduler` has been set to `Disabled`, you cannot change the value at runtime. Changing the value of the `event_scheduler` variable requires the SUPER privilege.

Since MariaDB 10.0.22, setting the event_scheduler system variable will also try to reload the mysql.event table if it was not properly loaded at startup.

Viewing Current Events

A list of current events can be obtained with the SHOW EVENTS statement. This only shows the event name and interval - the full event details, including the SQL, can be seen by querying the Information Schema EVENTS table, or with SHOW CREATE EVENT.

If an event is currently being executed, it can be seen by querying the Information Schema PROCESSLIST table, or with the SHOW PROCESSLIST statement.

Example

```
SHOW EVENTS\G;
*************************** 1. row ***************************
                  Db: test
                Name: test_event
             Definer: root@localhost
           Time zone: SYSTEM
                Type: RECURRING
          Execute at: NULL
      Interval value: 1
      Interval field: MINUTE
              Starts: 2013-05-20 13:46:56
                Ends: NULL
              Status: ENABLED
          Originator: 1
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

```
SHOW CREATE EVENT test_event\G
*************************** 1. row ***************************
               Event: test_event
            sql_mode:
           time_zone: SYSTEM
        Create Event: CREATE DEFINER=`root`@`localhost` EVENT `test_event` ON SCHEDULE EVERY 1 MINUTE
STARTS '2013-05-20 13:46:56' ON COMPLETION NOT PRESERVE ENABLE DO UPDATE test.t1 SET a = a + 1
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Altering Events

An event can be changed with the ALTER EVENT statement.

Example

```
ALTER EVENT test_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
```

Dropping Events

Events are dropped with the DROP EVENT statement. Events are also automatically dropped once they have run for the final time according to their schedule, unless the ON COMPLETION PRESERVE clause has been specified.

Example

```
DROP EVENT test_event;
Query OK, 0 rows affected (0.00 sec)
```

This page is licensed: CC BY-SA / Gnu FDL

ALTER EVENT

Modifies one or more characteristics of an existing event.

Syntax

```
ALTER
    [DEFINER = { user | CURRENT_USER }]
    EVENT event_name
    [ON SCHEDULE schedule]
    [ON COMPLETION [NOT] PRESERVE]
    [RENAME TO new_event_name]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'comment']
    [DO sql_statement]
```

Description

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE` / `DISABLE`, and `DO` clauses is exactly the same as when used with CREATE EVENT.

This statement requires the EVENT privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the SUPER privilege.)

`ALTER EVENT` works only with an existing event:

```
ALTER EVENT no_such_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
ERROR 1539 (HY000): Unknown event 'no_such_event'
```

Examples

```
ALTER EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 2 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

Event Limitations

The following restrictions apply to Events:

- All of the restrictions listed in Stored Routine Limitations.
- Events cannot return a result set.
- Event names are case insensitive, so it's not possible to define two events in the same database if their case insensitive names will match. This restriction has applied since MariaDB/MySQL 5.1.8. If you are upgrading from an older version of MySQL, and have events that could clash, these events need to be renamed before the upgrade.

- Events do not support dates beyond the maximum that can be represented in the Unix epoch (2038-01-19).
- Events cannot be created, dropped or altered by another stored program, trigger or event.
- Events cannot create, drop or alter stored programs or triggers
- Event timings cannot be strictly predicted. The intervals `MONTH`, `YEAR_MONTH`, `QUARTER`, and `YEAR` are all resolved in months. All others are resolved in seconds. A delay of up to two seconds is possible in extreme cases, and events scheduled to run at the same second cannot be executed in a given order. The `LAST_EXECUTED` column in the INFORMATION_SCHEMA.EVENTS table will however always be accurate to within a second.
- A new connection is used for each execution of statements within the body of an event, so the session counts for server status variables such as `Com_delete` and `Com_select` will not reflect these.
- Because the Event Scheduler depends on grant tables for its functionality, it is automatically disabled when the server is running with –skip-grant-tables.

Triggers

See Trigger Overview.

Complete MariaDB triggers overview: BEFORE/AFTER INSERT/UPDATE/DELETE timing, CREATE TRIGGER syntax, FOLLOWS|PRECEDES ordering, and DROP/SHOW TRIGGERS.

See CREATE TRIGGER.

Complete CREATE TRIGGER reference: OR REPLACE, DEFINER, IF NOT EXISTS, FOLLOWS/PRECEDES options for BEFORE/AFTER INSERT, UPDATE, or DELETE triggers rules.

See Trigger Limitations.

Understand the constraints of triggers, such as the prohibition of statements that return result sets or explicitly start/commit transactions.

See Triggers and Implicit Locks.

Explains how triggers can cause implicit locks on referenced tables during the execution of a statement, potentially affecting concurrency.

This page is licensed: CC BY-SA / Gnu FDL

Trigger Overview

A trigger is a set of statements that run when, or are triggered by, an event that occurs on a table.

Events

The event can be an `INSERT`, an `UPDATE`, or a `DELETE`. The trigger can be executed `BEFORE` or `AFTER` the event. A table can have multiple triggers defined for the same event and timing combination.

The LOAD DATA INFILE and LOAD XML statements invoke `INSERT` triggers for each row that is being inserted.

The REPLACE statement is executed with the following workflow:

- `BEFORE INSERT`;
- `BEFORE DELETE` (only if a row is being deleted);
- `AFTER DELETE` (only if a row is being deleted);
- `AFTER INSERT`.

The INSERT … ON DUPLICATE KEY UPDATE statement, when a row already exists, follows the following workflow:

- `BEFORE INSERT`;
- `BEFORE UPDATE`;
- `AFTER UPDATE`.

Otherwise, it works like a normal `INSERT` statement.

Note that TRUNCATE TABLE does not activate any triggers.

MariaDB Enterprise Server 12.3 adds a separate class of *conflict* triggers (`CREATE TRIGGER ... FOR CONFLICT`) that fire on a replica when a row-based replication event conflicts with the replica's local data. See Conflict Detection and Resolution (CDR) Triggers.

Triggers and Errors

With non-transactional storage engines, if a `BEFORE` statement produces an error, the statement isn't executed. Statements that affect multiple rows fail before inserting the current row.

With transactional engines, triggers are executed in the same transaction as the statement that invoked them.

If a warning is issued with the `SIGNAL` or `RESIGNAL` statement (that is, an error with an `SQLSTATE` starting with `'01'`), it is treated like an error.

Creating a Trigger

Here's a simple example to demonstrate a trigger in action. Using these two tables as an example:

```
CREATE TABLE animals (id MEDIUMINT(9)
NOT NULL AUTO_INCREMENT,
name CHAR(30) NOT NULL,
PRIMARY KEY (`id`));

CREATE TABLE animal_count (animals INT);

INSERT INTO animal_count (animals) VALUES(0);
```

We want to increment a counter each time a new animal is added. Here's what the trigger looks like:

```
CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

The trigger has:

- a name (in this case, `increment_animal`),
- a trigger time (in this case, after the specified trigger event),
- a trigger event (an `INSERT`),
- a table with which it is associated (`animals`),
- a set of statements to run (here, just the one `UPDATE` statement).

`AFTER INSERT` specifies that the trigger runs *after* an `INSERT`. The trigger could also be set to run *before*, and the statement causing the trigger could be a `DELETE` or an `UPDATE` as well. You can also have multiple triggers for an action. In this case, you can use `FOLLOWS | PRECEDES`` ``*other_trigger_name*` to specify the order of the triggers.

The set of statements to run are the statements on the table of the trigger; therefore, columns/values that change are always just a column name or an expression like `NEW.` *`column_name`*. Table references of other tables must come from explicit table references.

Now, if we insert a record into the `animals` table, the trigger runs, incrementing the *`animal_count`* table.

```
SELECT * FROM animal_count;
+---------+
| animals |
+---------+
|       0 |
+---------+

INSERT INTO animals (name) VALUES('aardvark');
INSERT INTO animals (name) VALUES('baboon');

SELECT * FROM animal_count;
+---------+
| animals |
+---------+
|       2 |
+---------+
```

For more details on the syntax, see CREATE TRIGGER.

Dropping Triggers

To drop a trigger, use the DROP TRIGGER statement. Triggers are also dropped if the table with which they are associated is also dropped.

```
DROP TRIGGER increment_animal;
```

Triggers Metadata

The Information Schema TRIGGERS Table stores information about triggers.

The SHOW TRIGGERS statement returns similar information.

The SHOW CREATE TRIGGER statement returns a `CREATE TRIGGER` statement that creates the given trigger.

More Complex Triggers

Triggers can consist of multiple statements enclosed by a BEGIN and END. If you're entering multiple statements on the command line, temporarily set a new delimiter so that you can use a semicolon to delimit the statements inside your trigger. See Delimiters in the mariadb client for more.

```
DROP TABLE animals;

UPDATE animal_count SET animals=0;

CREATE TABLE animals (id MEDIUMINT(9) NOT NULL AUTO_INCREMENT,
name CHAR(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=InnoDB;

DELIMITER //
CREATE TRIGGER the_mooses_are_loose
AFTER INSERT ON animals
FOR EACH ROW
BEGIN
 IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
 ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
 END IF;
END; //

DELIMITER ;

INSERT INTO animals (name) VALUES('Aardvark');

SELECT * FROM animal_count;
+---------+
| animals |
+---------+
|       1 |
+---------+

INSERT INTO animals (name) VALUES('Moose');

SELECT * FROM animal_count;
+---------+
| animals |
+---------+
|     101 |
+---------+
```

Trigger Errors

If a trigger contains an error and the engine is transactional, or it is a `BEFORE` trigger, the trigger will not run, and will prevent the original statement from running as well. If the engine is non-transactional, and it is an `AFTER` trigger, the trigger will not run, but the original statement will.

Here, we'll drop the above examples and then recreate the trigger with an error, a field that doesn't exist, first using the default InnoDB, a transactional engine, and then again using MyISAM, a non-transactional engine.

```
DROP TABLE animals;

CREATE TABLE animals (id MEDIUMINT(9) NOT NULL AUTO_INCREMENT,
name CHAR(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=InnoDB;

CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.id = animal_count_id+1;

INSERT INTO animals (name) VALUES('aardvark');
ERROR 1054 (42S22): Unknown column 'animal_count.id' in 'field list'

SELECT * FROM animals;
Empty set (0.00 sec)
```

And now the identical procedure, but with a MyISAM table.

```
DROP TABLE animals;

CREATE TABLE animals (id MEDIUMINT(9) NOT NULL AUTO_INCREMENT,
name CHAR(30) NOT NULL,
PRIMARY KEY (`id`))
ENGINE=MyISAM;

CREATE TRIGGER increment_animal
AFTER INSERT ON animals
FOR EACH ROW
UPDATE animal_count SET animal_count.id = animal_count_id+1;

INSERT INTO animals (name) VALUES('aardvark');
ERROR 1054 (42S22): Unknown column 'animal_count.id' in 'field list'

SELECT * FROM animals;
+----+----------+
| id | name     |
+----+----------+
|  1 | aardvark |
+----+----------+
```

The following example shows how to use a trigger to validate data. The SIGNAL statement is used to intentionally produce an error if the email field is not a valid email. As the example shows, in that case, the new row is not inserted (because it is a `BEFORE` trigger).

```
CREATE TABLE user (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    first_name CHAR(20),
    last_name CHAR(20),
    email CHAR(100)
)
    ENGINE = MyISAM;

DELIMITER //
CREATE TRIGGER bi_user
  BEFORE INSERT ON user
  FOR EACH ROW
BEGIN
  IF NEW.email NOT LIKE '_%@_%.__%' THEN
    SIGNAL SQLSTATE '45000' SET MESSAGE_TEXT = 'Email field IS NOT valid';
  END IF;
END; //
DELIMITER ;

INSERT INTO user (first_name, last_name, email) VALUES ('John', 'Doe', 'john_doe.example.net');
ERROR 1644 (45000): Email field is not valid

SELECT * FROM user;
Empty set (0.00 sec)
```

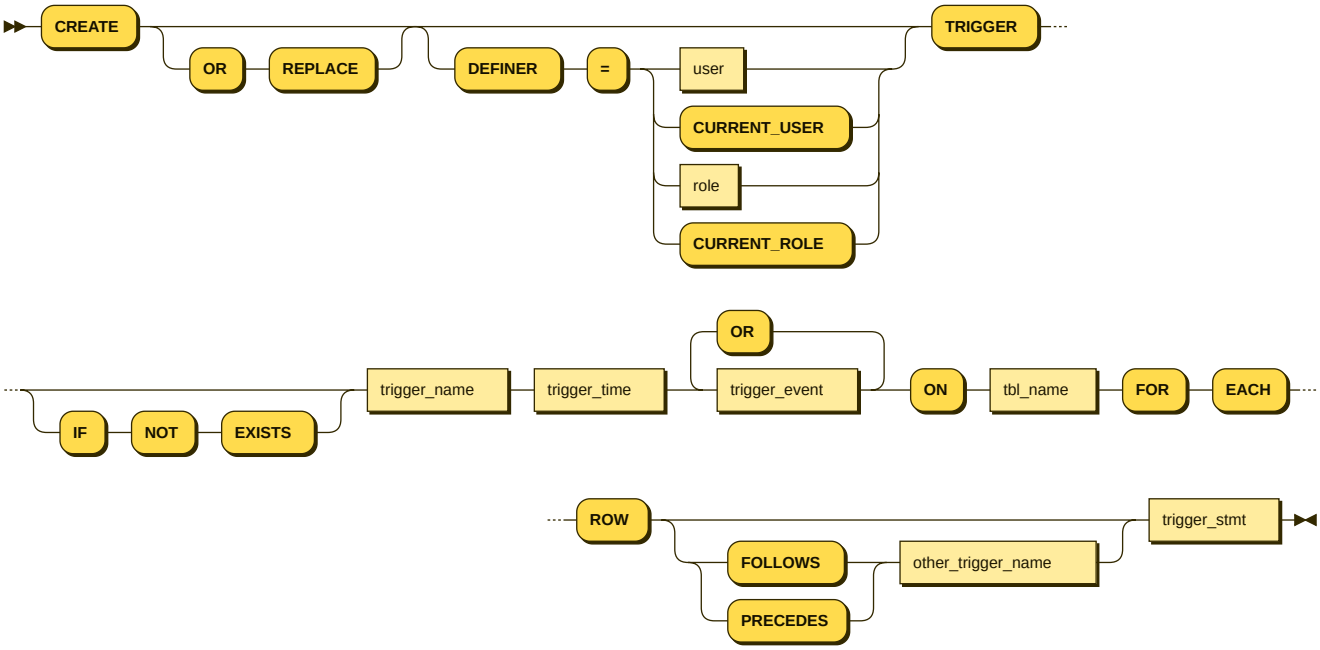
CREATE TRIGGER

Syntax

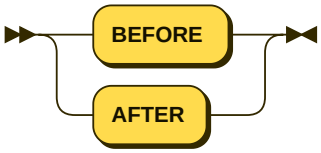
```
CREATE [OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    TRIGGER [IF NOT EXISTS]
            trigger_name trigger_time {trigger_event [OR trigger_event] ...}
    ON tbl_name FOR EACH ROW
    [{ FOLLOWS | PRECEDES } other_trigger_name]
    trigger_stmt

trigger_time:
    BEFORE
  | AFTER

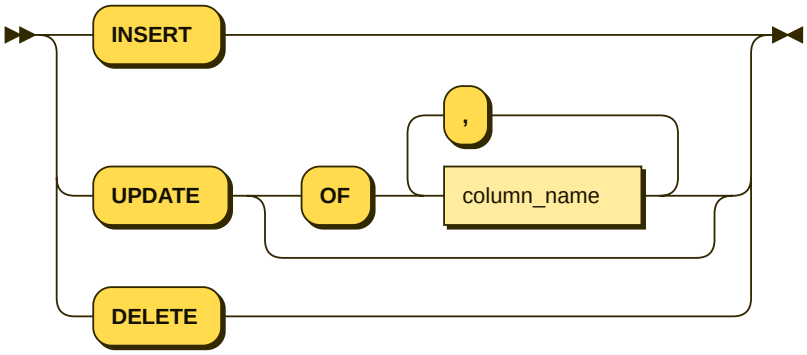
trigger_event:
    INSERT
  | UPDATE [OF column_name [, column_name] ...]
  | DELETE
```



Railroad diagram of CREATE TRIGGER — equivalent to the BNF above



Railroad diagram of trigger_time



Railroad diagram of trigger_event

> **Note:**
>
> MariaDB Enterprise Server 12.3 adds a third trigger form for replicas: `CREATE TRIGGER ... FOR CONFLICT`, which fires when a row-based replication event conflicts with the replica's local data. The `FOR CONFLICT` clause replaces the `BEFORE` / `AFTER` timing keyword and cannot be combined with the trigger events above. See Conflict Detection and Resolution (CDR) Triggers.

Description

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

`CREATE TRIGGER` requires the TRIGGER privilege for the table associated with the trigger.

You can have multiple triggers for the same *`trigger_time`* and *`trigger_event`*.

For valid identifiers to use as trigger names, see Identifier Names.

`trigger_stmt` is the statement executed when the trigger activates. Here, you can refer to columns in the table associated with the trigger using the aliases `OLD` and `NEW`. `OLD.` *`col_name`* refers to a column of an existing row before it is updated or deleted. `NEW.` *`col_name`* refers to the column of a new row to be inserted or an existing row after it is updated.

`OLD` and `NEW` are MariaDB (and MySQL) extensions to triggers. They are not case-sensitive.

Triggers cannot use `NEW.` *`col_name`* or use `OLD.` *`col_name`* to refer to generated columns. For information about generated columns, see Generated Columns.

In an `INSERT` trigger, only `NEW.` *`col_name`* can be used, because there is no old row. In a `DELETE` trigger, only `OLD.` *`col_name`* can be used, because there is no new row. In an `UPDATE` trigger, use `OLD.` *`col_name`* to refer to the columns of a row before it is updated, and `NEW.` *`col_name`* to refer to the columns of the row after it is updated.

A column referenced with `OLD` is read-only. If you have the `SELECT` privilege, this means you can refer to it, but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege. In a `BEFORE` trigger, you can also change its value with `SET NEW.` *`col_name`* ``` `=` ``` *`value`* if you have the `UPDATE` privilege. This means you can use a trigger to modify the values to be inserted as a new row or to update a row. In an `AFTER` trigger, a `SET` statement has no effect, because the row change has already occurred.

OR REPLACE

If used and the trigger already exists, instead of an error being returned, the existing trigger is dropped and replaced by the newly defined trigger.

DEFINER

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time. Usage requires the SET USER privilege.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, the trigger is created only if a trigger of the same name does not exist. If the trigger already exists, by default a warning is returned.

trigger_time

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

trigger_event

> **CURRENT**
>
> Multiple *`trigger_event`* events can be specified.
>
> **< 12.0**
>
> Only one *`trigger_event`* can be specified.

`trigger_event` indicates the kind of statement that activates the trigger. A `trigger_event` can be one of the following:

- `INSERT` : The trigger is activated whenever a new row is inserted into the table; for example, through INSERT, LOAD DATA, and REPLACE statements.
- `UPDATE` : The trigger is activated whenever a row is modified; for example, through UPDATE statements.

- `DELETE`: The trigger is activated whenever a row is deleted from the table; for example, through DELETE and REPLACE statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do not activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

`INSERTING`, `UPDATING`, and `DELETING` Predicates

When a trigger is defined for multiple events, the `INSERTING`, `UPDATING`, and `DELETING` predicates can be used within the trigger body to determine which event fired the trigger:

- `INSERTING`: Evaluates to `TRUE` when the `trigger_event` is `INSERT`
- `UPDATING`: Evaluates to `TRUE` when the `trigger_event` is `UPDATE`
- `DELETING`: Evaluates to `TRUE` when the `trigger_event` is `DELETE`

Example

```
CREATE TRIGGER t1_b_any BEFORE INSERT OR UPDATE OR DELETE ON t1 FOR EACH ROW
BEGIN
  IF INSERTING THEN
    INSERT INTO t2 VALUES (NEW.a, 'INSERTING');
  ELSEIF UPDATING THEN
    INSERT INTO t2 VALUES (NEW.a, 'UPDATING');
  ELSEIF DELETING THEN
    INSERT INTO t2 VALUES (OLD.a, 'DELETING');
  END IF;
END
```

FOLLOWS/PRECEDES *other_trigger_name*

The `FOLLOWS`` ``*other_trigger_name*` and `PRECEDES`` ``*other_trigger_name*` options support multiple triggers per action time.

`FOLLOWS` adds the new trigger after another trigger, while `PRECEDES` adds the new trigger before another trigger. If neither option is used, the new trigger is added last for the given action and time.

`FOLLOWS` and `PRECEDES` are not stored in the trigger definition. However, the trigger order is guaranteed to not change over time. mariadb-dump and other backup methods do not change trigger order.
You can verify the trigger order from the `ACTION_ORDER` column in INFORMATION_SCHEMA.TRIGGERS table.

```
SELECT trigger_name, action_order FROM information_schema.triggers
  WHERE event_object_table='t1';
```

Atomic DDL

> **CURRENT**
>
> MariaDB supports Atomic DDL, and `CREATE TRIGGER` is atomic.
>
> **< 10.6**
>
> MariaDB does **not** support Atomic DDL.

Examples

Creating a Trigger

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals FOR EACH ROW
   UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

`OR REPLACE` and `IF NOT EXISTS`

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
ERROR 1359 (HY000): Trigger already exists

CREATE OR REPLACE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals  FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected (0.12 sec)

CREATE DEFINER=`root`@`localhost` TRIGGER IF NOT EXISTS increment_animal
  AFTER INSERT ON animals FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+------------------------+
| Level | Code | Message                |
+-------+------+------------------------+
| Note  | 1359 | Trigger already exists |
+-------+------+------------------------+
1 row in set (0.00 sec)
```

Referencing NEW Column Values

```
DELIMITER //

CREATE TRIGGER trg_limit_population BEFORE UPDATE ON country_stats
FOR EACH ROW
BEGIN
    -- Ensure population is at least 1
    IF NEW.population < 1 THEN
        SET NEW.population = 1;
    -- Cap population at 2 billion for data integrity
    ELSEIF NEW.population > 2000000000 THEN
        SET NEW.population = 2000000000;
    END IF;
END;
//

DELIMITER ;
```

Trigger Limitations

The following restrictions apply to triggers:

- All of the restrictions listed in Stored Routine Limitations.
- All of the restrictions listed in Stored Function Limitations.

- Triggers are always executed for each row. MariaDB does not support the standard `FOR EACH STATEMENT` option.
- Triggers cannot operate on any tables in the mysql, `information_schema` or `performance_schema` database.
- Cannot return a result set.
- The RETURN statement is not permitted, since triggers don't return any values. Use LEAVE to immediately exit a trigger.
- Triggers are not activated by foreign key actions.
- If a trigger is loaded into cache, it is not automatically reloaded when the table metadata changes. In this case a trigger can operate using the outdated metadata.
- By default, with row-based replication, triggers run on the master, and the effects of their executions are replicated to the slaves. It is possible to run triggers on slaves. See Running triggers on the slave for Row-based events.

Triggers and Implicit Locks

A trigger may reference multiple tables, and if a LOCK TABLES statement is used on one of the tables, other tables may at the same time also implicitly be locked due to the trigger.

If the trigger only reads from the other table, that table are read locked. If the trigger writes to the other table, it is write-locked. If a table is read-locked for reading via `LOCK TABLES`, but needs to be write-locked because it could be modified by a trigger, a write lock is taken.

All locks are acquired together when the `LOCK TABLES` statement is issued, and released together on `UNLOCK TABLES`.

Example

```
LOCK TABLE table1 WRITE
```

Assume `table1` contains the following trigger:

```
CREATE TRIGGER trigger1 AFTER INSERT ON table1 FOR EACH ROW
BEGIN
  INSERT INTO table2 VALUES (1);
  UPDATE table3 SET writes = writes+1
    WHERE id = NEW.id AND EXISTS (SELECT id FROM table4);
END;
```

Not only is `table1` write locked, `table2` and `table3` are also write locked, due to the possible INSERT and UPDATE, while `table4` is read locked due to the SELECT.

User-Defined Functions

See User-Defined Functions Overview.

An introduction to User-Defined Functions (UDFs) in MariaDB, explaining how they extend the server's functionality by adding new native-like functions.

See Creating User-Defined Functions.

A guide for developers on writing UDFs in C/C++, covering the required interface functions, memory allocation, and thread safety.

See CREATE FUNCTION UDF.

Install a user-defined function from a shared library. This command loads an external compiled function into the server for extended capabilities.

See DROP FUNCTION UDF.

Documentation for the DROP FUNCTION statement, which uninstalls a UDF and removes its entry from the system table.

See User-Defined Functions Calling Sequences.

Technical details on the execution flow of UDFs, explaining the sequence in which initialization, processing, and de-initialization functions are called.

See User-Defined Functions Security.

Overview of security measures for UDFs, including file location restrictions, required privileges, and system variable configurations.

This page is licensed: CC BY-SA / Gnu FDL

User-Defined Functions Overview

A user-defined function (UDF) is a historical way to extend MariaDB with a new function that works similar to a native (built-in) MariaDB function such as ABS( ) or CONCAT( ). It was introduced in 1998 and is generally limited to supporting features that existed at that time.

Statements making use of user-defined functions are not safe for replication.

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs go to the UDF Repository on GitHub.

There are alternative ways to add a new function: a native function, which requires modifying and compiling the server source code; a function plugin; or a stored function.

This page is licensed: CC BY-SA / Gnu FDL

Creating User-Defined Functions

User-defined functions allow MariaDB to be extended with a new function that works like a native (built-in) MariaDB function such as ABS() or CONCAT(). It was introduced in 1998 and is generally limited to supporting features that existed at that time. There are alternative ways to add a new function: a native function, which requires modifying and compiling the server source code; a function plugin; or a stored function.

Statements making use of user-defined functions are not safe for replication.

Functions are written in C or C++, and to make use of them, the operating system must support dynamic loading.

Each new SQL function requires corresponding functions written in C/C++. In the list below, at least the main function - x() - and one other, are required. *x* should be replaced by the name of the function you are creating.

All functions need to be thread-safe, so not global or static variables that change can be allocated. Memory is allocated in `x_init()` and freed in `x_deinit()`.

Simple Functions

x()

Required for all UDFs; this is where the results are calculated.

C/C++ type	SQL type
char *	STRING
long long	INTEGER
double	REAL

`DECIMAL` functions return string values, and so should be written accordingly. It is not possible to create `ROW` functions.

x_init()

Initialization function for `x()`. Can be used for the following:

- Check the number of arguments to `X()` (the SQL equivalent).
- Verify the argument types, or to force arguments to be of a particular type after the function is called.
- Specify whether the result can be `NULL`.
- Specify the maximum result length.
- For `REAL` functions, specify the maximum number of decimals for the result.
- Allocate any required memory.

x_deinit()

De-initialization function for `x()`. Used to de-allocate memory that was allocated in `x_init()`.

Description

Each time the SQL function `X()` is called:

- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup are performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- If there is no `x_init()` function, or it has been called and did not return an error, x() is then called once per row.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.
- See User-defined Functions Calling Sequences for more details on the functions.

Aggregate Functions

The following functions are required for aggregate functions, such as AVG() and SUM(). When using CREATE FUNCTION, the AGGREGATE keyword is required.

x_clear()

Used to reset the current aggregate, but without inserting the argument as the initial aggregate value for the new group.

x_add()

Used to add the argument to the current aggregate.

x_remove()

Improves the support of window functions (so it is not obligatory to add it) and should remove the argument from the current aggregate.

Description

Each time the aggregate SQL function `X()` is called:

- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup are performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- If there is no `x_init()` function, or it has been called and did not return an error, `x()` is then called once per row.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.
- MariaDB will first call the C/C++ initialization function, `x_init()`, assuming it exists. All setup are performed, and if it returns an error, the SQL statement is aborted and no further functions are called.
- The table is sorted according to the GROUP BY expression.
- `x_clear()` is called for the first row of each new group.
- `x_add()` is called once per row for each row in the same group.
- `x()` is called when the group changes, or after the last row, to get the aggregate result.
- The latter three steps are repeated until all rows have been processed.
- After all rows have finished processing, `x_deinit()` is called, if present, to clean up by de-allocating any memory that was allocated in `x_init()`.

Examples

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs see mysqludf.

CREATE FUNCTION UDF

Syntax

```
CREATE [OR REPLACE] [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
    RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

Description

A user-defined function (UDF) is a way to extend MariaDB with a new function that works like a native (built-in) MariaDB function such as ABS() or CONCAT().

`function_name` is the name that should be used in SQL statements to invoke the function.

To create a function, you must have the INSERT privilege for the mysql database. This is necessary because `CREATE FUNCTION` adds a row to the mysql.func system table that records the function's name, type, and shared library name. If you do not have this table, you should run the mariadb-upgrade command to create it.

UDFs need to be written in C, C++ or another language that uses C calling conventions, MariaDB needs to have been dynamically compiled, and your operating system must support dynamic loading.

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs see sql-udf.

Statements making use of user-defined functions are not safe for replication.

For creating a stored function as opposed to a user-defined function, see CREATE FUNCTION.

For valid identifiers to use as function names, see Identifier Names.

RETURNS

The `RETURNS` clause indicates the type of the function's return value, and can be one of string, INTEGER, REAL or DECIMAL. `DECIMAL` functions currently return string values and should be written like STRING functions.

shared_library_name

`shared_library_name` is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the plugin_dir system variable. Note that before MariaDB/MySQL 5.1, the shared object could be located in any directory that was searched by your system's dynamic linker.

AGGREGATE

Aggregate functions are summary functions such as SUM() and AVG().
Aggregate UDF functions can be used as window functions.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION name ...;
```

IF NOT EXISTS

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified function already exists. Cannot be used together with OR REPLACE.

Upgrading a UDF

To upgrade the UDF's shared library, first run a DROP FUNCTION statement, then upgrade the shared library and finally run the CREATE FUNCTION statement. If you upgrade without following this process, you may crash the server.

Examples

```
CREATE FUNCTION jsoncontains_path RETURNS INTEGER SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)
```

OR REPLACE and IF NOT EXISTS:

```
CREATE FUNCTION jsoncontains_path RETURNS INTEGER SONAME 'ha_connect.so';
ERROR 1125 (HY000): Function 'jsoncontains_path' already exists

CREATE OR REPLACE FUNCTION jsoncontains_path RETURNS INTEGER SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)

CREATE FUNCTION IF NOT EXISTS jsoncontains_path RETURNS INTEGER SONAME 'ha_connect.so';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------+
| Level | Code | Message                                 |
+-------+------+-----------------------------------------+
| Note  | 1125 | Function 'jsoncontains_path' already exists |
+-------+------+-----------------------------------------+
```

See Also

- Identifier Names
- DROP FUNCTION
- CREATE FUNCTION

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP FUNCTION UDF

Syntax

```
DROP FUNCTION [IF EXISTS] function_name
```

Description

This statement drops the user-defined function (UDF) named `function_name`.

To drop a function, you must have the DELETE privilege for the mysql database. This is because `DROP FUNCTION` removes the row from the mysql.func system table that records the function's name, type and shared library name.

For dropping a stored function, see DROP FUNCTION.

Upgrading a UDF

To upgrade the UDF's shared library, first run a DROP FUNCTION statement, then upgrade the shared library and finally run the CREATE FUNCTION statement. If you upgrade without following this process, you may crash the server.

Examples

```
DROP FUNCTION jsoncontains_path;
```

IF EXISTS:

```
DROP FUNCTION jsoncontains_path;
ERROR 1305 (42000): FUNCTION test.jsoncontains_path does not exist

DROP FUNCTION IF EXISTS jsoncontains_path;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------+
| Level | Code | Message                                       |
+-------+------+-----------------------------------------------+
| Note  | 1305 | FUNCTION test.jsoncontains_path does not exist |
+-------+------+-----------------------------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

User-Defined Functions Calling Sequences

The functions described in Creating User-defined Functions are expanded on this page. They are declared as follows:

Simple Functions

x()

If `x()` returns an integer, it is declared as follows:

```
long long x(UDF_INIT *initid, UDF_ARGS *args,
            char *is_null, char *error);
```

If `x()` returns a string (`DECIMAL` functions also return string values), it is declared as follows:

```
char *x(UDF_INIT *initid, UDF_ARGS *args,
        char *result, unsigned long *length,
        char *is_null, char *error);
```

If `x()` returns a real, it is declared as follows:

```
double x(UDF_INIT *initid, UDF_ARGS *args,
            char *is_null, char *error);
```

x_init()

```
my_bool x_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
```

x_deinit()

```
void x_deinit(UDF_INIT *initid);
```

Description

`initid` is a parameter passed to all three functions that points to a *UDF_INIT* structure, used for communicating information between the functions. Its structure members are:

- `my_bool maybe_null`
  - maybe_null should be set to 1 if x_init can return a NULL value, Defaults to 1 if any arguments are declared maybe_null.
- `unsigned int decimals`

    - Number of decimals after the decimal point. The default, if an explicit number of decimals is passed in the arguments to the main function, is the maximum number of decimals, so if 9.5, 9.55 and 9.555 are passed to the function, the default would be three (based on 9.555, the maximum). If there are no explicit number of decimals, the default is set to 31, or one more than the maximum for the `DOUBLE`, `FLOAT` and `DECIMAL` types. This default can be changed in the function to suit the actual calculation.

- `unsigned int max_length`
    - Maximum length of the result. For integers, the default is 21. For strings, the length of the longest argument. For reals, the default is 13 plus the number of decimals indicated by `initid->decimals`. The length includes any signs or decimal points. Can also be set to 65KB or 16MB in order to return a `BLOB`. The memory remains unallocated, but this is used to decide on the data type to use if the data needs to be temporarily stored.

- `char *ptr`
    - A pointer for use as required by the function. Commonly, `initid->ptr` is used to communicate allocated memory, with `x_init()` allocating the memory and assigning it to this pointer, `x()` using it, and `x_deinit()` de-allocating it.

- `my_bool const_item`
    - Should be set to 1 in `x_init()` if `x()` always returns the same value, otherwise `0`.

Aggregate Functions

x_clear()

x_clear() is a required function for aggregate functions, and is declared as follows:

```
void x_clear(UDF_INIT *initid, char *is_null, char *error);
```

It is called when the summary results need to be reset, that is at the beginning of each new group. but also to reset the values when there were no matching rows.

is_null is set to point to CHAR(0) before calling x_clear().

In the case of an error, you can store the value to which the error argument points (a single-byte variable, not a string buffer) in the variable.

x_reset()

x_reset() is declared as follows:

```
void x_reset(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

It is called on finding the first row in a new group. Should reset the summary variables, and then use *UDF_ARGS* as the first value in the group's internal summary value. The function is not required if the UDF interface uses *x_clear()*.

x_add()

x_add() is declared as follows:

```
void x_add(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

It is called for all rows belonging to the same group, and should be used to add the value in *UDF_ARGS* to the internal summary variable.

x_remove()

x_remove() was added in MariaDB 10.4 and is declared as follows (same as *x_add()*):

```
void x_remove(UDF_INIT* initid, UDF_ARGS* args,
              char* is_null, char *error );
```

It adds more efficient support of aggregate UDFs as window functions. *x_remove()* should "subtract" the row (reverse *x_add()*). In MariaDB 10.4 aggregate UDFs will work as WINDOW functions without *x_remove()* but it will not be so efficient.

If *x_remove()* supported (defined) detected automatically.

User-Defined Functions Security

The MariaDB server imposes a number of limitations on user-defined functions for security purposes.

- The `INSERT` privilege for the mysql database is required to run CREATE FUNCTION, as a record are added to the mysql.func-table.
- The `DELETE` privilege for the mysql database is required to run DROP FUNCTION as the corresponding record are removed from the mysql.func-table.
- UDF object files can only be placed in the plugin directory, as specified by the value of the plugin_dir system variable.
- At least one symbol, beyond the required `x()` , corresponding to an SQL function `X()`, is required. These can be `x_init()`, `x_deinit()`, `xxx_reset()`, `x_clear()`, and `x_add()` functions (see Creating User-defined Functions). The allow-suspicious-udfs mariadbd option (by default unset) provides a workaround, permitting only one symbol to be used. This is not recommended, as it opens the possibility of loading shared objects that are not legitimate user-defined functions.

Views

See ALTER VIEW.

Documentation for the ALTER VIEW statement, which is used to modify an existing view's definition without dropping and recreating it.

See CREATE VIEW.

Complete CREATE VIEW reference: OR REPLACE/IF NOT EXISTS, ALGORITHM=MERGE|TEMPTABLE|UNDEFINED, DEFINER/CURRENT_USER, and SQL SECURITY DEFINER|INVOKER.

See DROP VIEW.

Explains how to use the DROP VIEW statement to remove one or more views from the database, including required privileges.

See Information Schema VIEWS Table.

Describes the VIEWS table in the Information Schema, which provides metadata about all views in the database, such as definition and check options.

See Inserting and Updating with Views.

Covers the conditions under which a view is updatable, allowing INSERT, UPDATE, and DELETE operations to modify the underlying base tables.

See View Algorithms.

Learn about the different algorithms (MERGE, TEMPTABLE, UNDEFINED) MariaDB uses to process views and how they impact performance and updatability.

ALTER VIEW

Syntax

```
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

Description

This statement changes the definition of a view, which must exist. The syntax is similar to that for CREATE VIEW and the effect is the same as for `CREATE OR REPLACE VIEW` if the view exists. This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is allowed only to the definer or users with the SUPER privilege.

Example

```
ALTER VIEW v AS SELECT a, a*3 AS a2 FROM t;
```

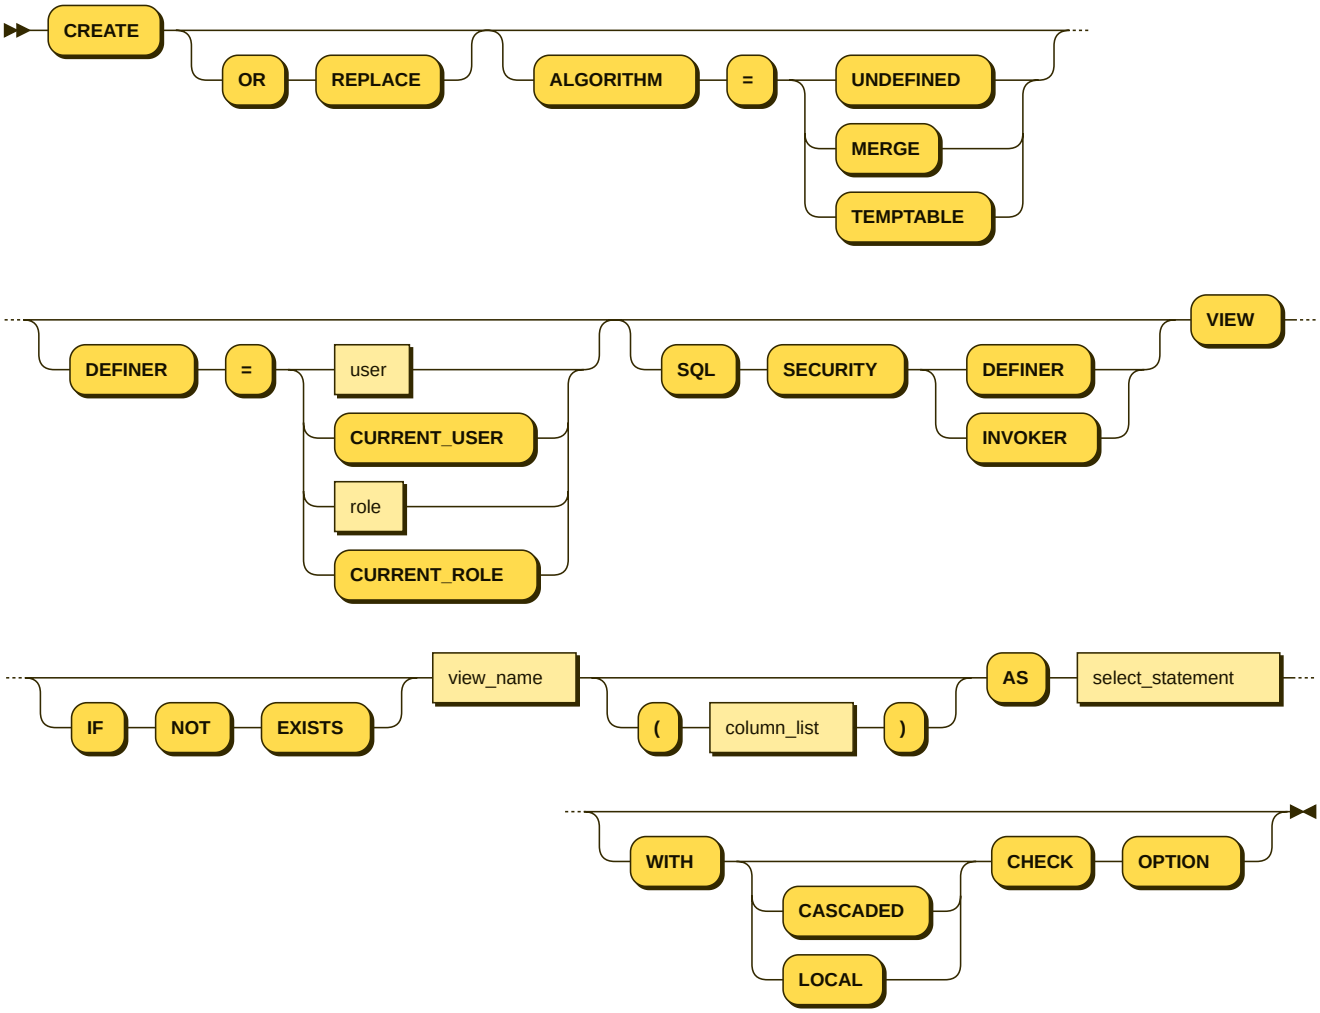
CREATE VIEW

Syntax

```
CREATE
    [OR REPLACE]
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW [IF NOT EXISTS] view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```



Railroad diagram of CREATE VIEW — equivalent to the BNF above

Description

The `CREATE VIEW` statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as ALTER VIEW.

The `select_statement` is a SELECT statement that provides the definition of the view. (When you select from the view, you select in effect using the `SELECT` statement.) select_statement can select from base tables or other views.

The view definition is “frozen” at creation time, so changes to the underlying tables afterwards do not affect the view definition. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view. A SHOW CREATE VIEW shows that such queries are rewritten and column names are included in the view definition.

The view definition must be a query that does not return errors at view creation times. However, the base tables used by the views might be altered later and the query may not be valid anymore. In this case, querying the view will result in an error. CHECK TABLE helps in finding this kind of problems.

The ALGORITHM clause affects how MariaDB processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the

`SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as db_name.view_name when you create it.

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional column_list clause can be given as a list of comma-separated identifiers. The number of names in column_list must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
CREATE TABLE t (qty INT, price INT);

INSERT INTO t VALUES(3, 50);

CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;

SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- For valid identifiers to use as view names, see Identifier Names.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, and `LOCK IN SHARE MODE`.

The `PROCEDURE` clause cannot be used in a view definition, and it cannot be used if a view is referenced in the `FROM` clause.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
CREATE VIEW v (mycol) AS SELECT 'abc';

SET sql_mode = '';

SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| mycol |
+-------+

SET sql_mode = 'ANSI_QUOTES';

SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| abc   |
+-------+
```

The `DEFINER` and `SQL SECURITY` clauses determine which MariaDB account to use when checking access privileges for the view when a statement is executed that references the view. The legal `SQL SECURITY` characteristic values are `DEFINER` and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default `SQL SECURITY` value is `DEFINER`.

If a user value is given for the `DEFINER` clause, it should be a MariaDB account in `'user_name'@'host_name'` format (the same format used in the `GRANT` statement). The user_name and host_name values both are required. The definer can also be given as `CURRENT_USER` or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the legal `DEFINER` user values:

- If you do not have the SET USER privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the SET USER privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- If the SQL `SECURITY` value is `DEFINER` but the definer account does not exist when the view is referenced, an error occurs.

Within a view definition, `CURRENT_USER` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for the view's invoker. For information about user auditing within views, see account-activity-auditing.html.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a program, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a `SQL SECURITY` characteristic of `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of its creator. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);

Suppose that f() contains a statement such AS this:

IF name IS NULL THEN
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY INVOKER`.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a `SQL SECURITY DEFINER` clause and with a `DEFINER` value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a `DEFINER` clause.

The optional `ALGORITHM` clause is an extension to standard SQL. It affects how MariaDB processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. See View Algorithms for more information.

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. See Inserting and Updating with Views.

WITH CHECK OPTION

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts or updates to rows except those for which the `WHERE` clause in the select_statement is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADED`.

For more information about updatable views and the `WITH CHECK OPTION` clause, see Inserting and Updating with Views.

IF NOT EXISTS

When the I`F NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified view already exists. Cannot be used together with the `OR REPLACE` clause.

Atomic DDL

MariaDB 10.6.1 supports Atomic DDL and `CREATE VIEW` is atomic.

Examples

```
CREATE TABLE t (a INT, b INT) ENGINE = InnoDB;

INSERT INTO t VALUES (1,1), (2,2), (3,3);

CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;

SELECT * FROM v;
+------+------+
| a    | a2   |
+------+------+
|    1 |    2 |
|    2 |    4 |
|    3 |    6 |
+------+------+
```

OR REPLACE and IF NOT EXISTS:

```
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;
ERROR 1050 (42S01): Table 'v' already exists

CREATE OR REPLACE VIEW v AS SELECT a, a*2 AS a2 FROM t;
Query OK, 0 rows affected (0.04 sec)

CREATE VIEW IF NOT EXISTS v AS SELECT a, a*2 AS a2 FROM t;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+--------------------------+
| Level | Code | Message                  |
+-------+------+--------------------------+
| Note  | 1050 | Table 'v' already exists |
+-------+------+--------------------------+
```

This page is licensed: GPLv2, originally from fill_help_tables.sql

DROP VIEW

Syntax

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

Description

`DROP VIEW` removes one or more views. You must have the DROP privilege for each view. If any of the views named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See SHOW WARNINGS.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

It is possible to specify view names as `db_name.view_name`. This is useful to delete views from multiple databases with one statement. See Identifier Qualifiers for details.

The DROP privilege is required to use `DROP TABLE` on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

If a view references another view, it are possible to drop the referenced view. However, the other view will reference a view which does not exist any more. Thus, querying it will produce an error similar to the following:

```
ERROR 1356 (HY000): View 'db_name.view_name' references invalid table(s) or
column(s) or function(s) or definer/invoker of view lack rights to use them
```

This problem is reported in the output of CHECK TABLE.

Note that it is not necessary to use `DROP VIEW` to replace an existing view, because CREATE VIEW has an `OR REPLACE` clause.

Atomic DDL

MariaDB 10.6.1 supports Atomic DDL and `DROP VIEW` for a singular view is atomic. Dropping multiple views is crash-safe.

Examples

```
DROP VIEW v,v2;
```

Given views `v` and `v2`, but no view `v3`

```
DROP VIEW v,v2,v3;
ERROR 1051 (42S02): Unknown table 'v3'
```

```
DROP VIEW IF EXISTS v,v2,v3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-------------------------+
| Level | Code | Message                 |
+-------+------+-------------------------+
| Note  | 1051 | Unknown table 'test.v3' |
+-------+------+-------------------------+
```

Information Schema VIEWS Table

The Information Schema `VIEWS` table contains information about views. The `SHOW VIEW` privilege is required to view the table.

It has the following columns:

Column	Description
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name containing the view.
TABLE_NAME	View table name.
VIEW_DEFINITION	Definition of the view.
CHECK_OPTION	YES if the WITH CHECK_OPTION clause has been specified, NO otherwise.
IS_UPDATABLE	Whether the view is updatable or not.
DEFINER	Account specified in the DEFINER clause (or the default when created).
SECURITY_TYPE	SQL SECURITY characteristic, either DEFINER or INVOKER.
CHARACTER_SET_CLIENT	The client character set when the view was created, from the session value of the character_set_client system variable.
COLLATION_CONNECTION	The client collation when the view was created, from the session value of the collation_connection system variable.
ALGORITHM	The algorithm used in the view. See View Algorithms.

Example

```
SELECT * FROM information_schema.VIEWS\G
*************************** 1. row ***************************
       TABLE_CATALOG: def
        TABLE_SCHEMA: test
          TABLE_NAME: v
     VIEW_DEFINITION: SELECT `test`.`t`.`qty` AS `qty`,`test`.`t`.`price` AS `price`,(`test`.`t`.`qty` *
`test`.`t`.`price`) AS `value` FROM `test`.`t`
        CHECK_OPTION: NONE
        IS_UPDATABLE: YES
             DEFINER: root@localhost
       SECURITY_TYPE: DEFINER
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
           ALGORITHM: UNDEFINED
```

Inserting and Updating with Views

A view can be used for inserting or updating. However, there are certain limitations.

Updating with Views

A view cannot be used for updating if it uses any of the following:

- `ALGORITHM=TEMPTABLE` (see View Algorithms)
- HAVING
- GROUP BY
- DISTINCT
- UNION
- UNION ALL
- An aggregate function, such as MAX(), MIN(), SUM() or COUNT()
- Subquery in the `SELECT` list
- Subquery in the `WHERE` clause referring to a table in the `FROM` clause
- If it has no underlying table because it refers only to literal values
- The `FROM` clause contains a non-updatdable view.
- Multiple references to any base table column
- An outer join
- An inner join where more than one table in the view definition is being updated
- If there's a `LIMIT` clause, the view does not contain all primary or not null unique key columns from the underlying table and the updatable_views_with_limit system variable is set to `0`.

Inserting with Views

A view cannot be used for inserting if it fails any of the criteria for updating, and must also meet the following conditions:

- the view contains all base table columns that don't have default values
- no base table columns are present in view select list more than once
- the view columns are all simple columns, and not derived in any way. The following are examples of derived columns
  - column_name + 25
  - LOWER(column_name)
  - (subquery)
  - 9.5
  - column1 / column2

Checking Whether a View is Updatable

MariaDB stores an IS_UPDATABLE flag with each view, so it is always possible to see if MariaDB considers a view updatable (although not necessarily insertable) by querying the IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table.

WITH CHECK OPTION

The WITH CHECK OPTION clause is used to prevent updates or inserts to views unless the WHERE clause in the SELECT statement is true.

There are two keywords that can be applied. WITH LOCAL CHECK OPTION restricts the CHECK OPTION to only the view being defined, while WITH CASCADED CHECK OPTION checks all underlying views as well. CASCADED is treated as default if neither keyword is given.

If a row is rejected because of the CHECK OPTION, an error similar to the following is produced:

```
ERROR 1369 (HY000): CHECK OPTION failed 'db_name.view_name'
```

A view with a WHERE which is always false (like `WHERE 0`) and WITH CHECK OPTION is similar to a BLACKHOLE table: no row is ever inserted and no row is ever returned. An insertable view with a WHERE which is always false but no CHECK OPTION is a view that accepts data but does not show them.

Examples

```
CREATE TABLE table1 (x INT);

CREATE VIEW view1 AS SELECT x, 99 AS y FROM table1;
```

Checking whether the view is updateable:

```
SELECT TABLE_NAME,IS_UPDATABLE FROM INFORMATION_SCHEMA.VIEWS;
+------------+--------------+
| TABLE_NAME | IS_UPDATABLE |
+------------+--------------+
| view1      | YES          |
+------------+--------------+
```

This query works, as the view is updateable:

```
UPDATE view1 SET x = 5;
```

This query fails, since column `y` is a literal.

```
UPDATE view1 SET y = 5;
ERROR 1348 (HY000): Column 'y' is not updatable
```

Here are three views to demonstrate the WITH CHECK OPTION clause.

```
CREATE VIEW view_check1 AS SELECT * FROM table1 WHERE x < 100 WITH CHECK OPTION;

CREATE VIEW view_check2 AS SELECT * FROM view_check1 WHERE x > 10 WITH LOCAL CHECK OPTION;

CREATE VIEW view_check3 AS SELECT * FROM view_check1 WHERE x > 10 WITH CASCADED CHECK OPTION;
```

This insert succeeds, as `view_check2` only checks the insert against `view_check2`, and the WHERE clause evaluates to true (`150` is `>10`).

```
INSERT INTO view_check2 VALUES (150);
```

This insert fails, as `view_check3` checks the insert against both `view_check3` and the underlying views. The WHERE clause for `view_check1` evaluates as false (`150` is `>10`, but `150` is not `<100`), so the insert fails.

```
INSERT INTO view_check3 VALUES (150);
ERROR 1369 (HY000): CHECK OPTION failed 'test.view_check3'
```

View Algorithms

Description

The CREATE VIEW statement accepts an optional `ALGORITHM` clause, an extension to standard SQL for Views.

It can contain one of three values: `MERGE`, `TEMPTABLE` or `UNDEFINED`, and affects how MariaDB will process the view.

With `MERGE`, the view definition and the related portion of the statement referring to the view are merged. If `TEMPTABLE` is selected, the view results are stored in a temporary table.

`MERGE` is usually more efficient, and a view can only be updated with this algorithm. `TEMPTABLE` can be useful in certain situations, as locks on the underlying tables can be released before the statement is finished processing.

If it's `UNDEFINED` (or the `ALGORITHM` clause is not used), MariaDB will choose what it thinks is the best algorithm. An algorithm can also be `UNDEFINED` if its defined as `MERGE`, but the view requires a temporary table.

Views with definition `ALGORITHM=MERGE` or `ALGORITHM=TEMPTABLE` got accidentally swapped between MariaDB and MySQL. When upgrading, you have to re-create views created with either of these definitions (see MDEV-6916).

MERGE Limitations

A view cannot be of type `ALGORITHM=MERGE` if it uses any of the following:

- HAVING
- LIMIT
- GROUP BY
- DISTINCT
- UNION
- UNION ALL
- An aggregate function, such as MAX(), MIN(), SUM() or COUNT()
- subquery in the `SELECT` list
- if it has no underlying table because it refers only to literal values

MERGE Examples

Example 1

Here's an example of how MariaDB handles a view with a `MERGE` algorithm. Take a view defined as follows:

```
CREATE ALGORITHM = MERGE VIEW view_name (view_field1, view_field2) AS
SELECT field1, field2 FROM table_name WHERE field3 > '2013-06-01';
```

Now, if we run a query on this view, as follows:

```
SELECT * FROM view_name;
```

to execute the view `view_name` becomes the underlying table, `table_name`, the `*` becomes the fields `view_field1` and `view_field2`, corresponding to `field1` and `field2` and the `WHERE` clause, `WHERE field3 > 100` is added, so the actual query executed is:

```
SELECT field1, field2 FROM table_name WHERE field3 > '2013-06-01'
```

Example 2

Given the same view as above, if we run the query:

```
SELECT * FROM view_name WHERE view_field < 8000;
```

Everything occurs as it does in the previous example, but `view_field < 8000` takes the corresponding field name and becomes `field1 < 8000`, connected with `AND` to the `field3 > '2013-06-01'` part of the query.

So the resulting query is:

```
SELECT field1, field2 FROM table_name WHERE (field3 > '2013-06-01') AND (field1 < 8000);
```

When connecting with `AND`, parentheses are added to make sure the correct precedence is used.

MariaDB Package Repository Setup and Usage

Overview

If you are looking to set up MariaDB Server, it is often easiest to use a repository. MariaDB Corporation provides two convenient shell scripts to configure access to their MariaDB Package Repositories:

- `mariadb_es_repo_setup` for MariaDB Enterprise Server, which can be downloaded from:
  - https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
- `mariadb_repo_setup` for MariaDB Community Server, which can be downloaded from:
  - https://r.mariadb.com/downloads/mariadb_repo_setup

> **Note:**
>
> **Using the MariaDB Foundation's Repository Configuration Tool**
>
> Another option for MariaDB Community Server is to use the MariaDB Foundation's repository configuration tool. Visit https://mariadb.org/download/?t=repo-config and follow the instructions from there. It will ask for your Linux distribution, desired MariaDB version, and the mirror to use, and will show what files to edit and what commands to run to configure a Community Server repository.

Using MariaDB Corporation's Repository Setup Scripts

Downloading and Verifying the Scripts

The scripts can be downloaded and verified in the following ways:

> **MARIADB_ES_REPO_SETUP**
>
> Download the script:

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

Verify the checksum of the script:

```
echo "${checksum} mariadb_es_repo_setup" | sha256sum -c -
```

MARIADB_REPO_SETUP

Download the script:

```
curl -LsSO https://r.mariadb.com/downloads/mariadb_repo_setup
```

Verify the checksum of the script:

```
echo "${checksum} mariadb_repo_setup" | sha256sum -c -
```

Note:

Checksums of the various releases of the MariaDB Corporation's repository setup scripts can be found in the Versions section at the bottom of this page. Substitute `${checksum}` in the example above with the checksum of the version of the script you are using.

The version number is a date and can be found by running the script with the `--version` option, or by opening the script in a text editor and looking at line 4, `version="..."`.

Script Prerequisites

For the scripts to work, the `curl` package needs to be installed on your system. Additionally, on Debian and Ubuntu, the `apt-transport-https` package needs to be installed. The script will check if these are installed and let you know before it attempts to create the repository configuration on your system.

They can be installed on your system as follows:

RHEL / ROCKY / ALMA

```
sudo dnf install curl
```

DEBIAN / UBUNTU

```
sudo apt update
sudo apt install curl apt-transport-https
```

SLES

```
sudo zypper install curl
```

Running the Scripts

After the script you are using is downloaded, you need to run it with `root` user permissions. This is normally accomplished using the `sudo` command:

MARIADB_ES_REPO_SETUP

Retrieve your customer downloads token:

1. Navigate to https://customers.mariadb.com/downloads/token/ and log in

2. Copy the Customer Download Token
3. Substitute your token for `${token}` when running the `mariadb_es_repo_setup` script, below
4. Set the script to be executable:

```
chmod +x mariadb_es_repo_setup
```

5. Run the script:

```
sudo ./mariadb_es_repo_setup --token="${token}" --apply
```

MARIADB_REPO_SETUP

1. Set the script to be executable:

```
chmod +x mariadb_repo_setup
```

2. Run the script:

```
sudo ./mariadb_repo_setup
```

Repositories

▼ MariaDB Enterprise Repositories

MariaDB Enterprise Repositories

The `mariadb_es_repo_setup` script will set up different repositories in a single repository configuration file. The default repositories set up by the script are:

- MariaDB Enterprise Server Repository
  - Debug packages via the `main/debug` component *(Ubuntu only)*
- MariaDB Enterprise MaxScale Repository
- MariaDB Enterprise Tools Repository

> **Note:**
>
> On Ubuntu, MariaDB Server debug packages are provided through an additional `main/debug` component in the MariaDB Server repository configuration, which the script enables automatically. Other Linux distributions include the debug packages in the main repository. Debug packages should normally only be installed for specific purposes under the direction of a qualified support engineer.

> **Note:**
>
> The **Tools** repository (not Enterprise Tools) is no longer configured by default. If you need it, run the script with the `--include-tools` option.

The `mariadb_es_repo_setup` script configures the MariaDB Enterprise repositories. These are hosted on the MariaDB customer download server (`dlm.mariadb.com`) and require a valid customer download token, which you supply with the `--token` option (see Run the Script for how to retrieve your token).

By default, `mariadb_es_repo_setup` configures three Enterprise repositories: MariaDB Enterprise Server, MariaDB Enterprise Tools, and MariaDB Enterprise MaxScale. It can also configure the Unsupported repository on request.

MariaDB Enterprise Server Repository

The **MariaDB Enterprise Server** repository software packages related to MariaDB Enterprise Server, including: the server itself, clients and utilities, client libraries, plugins, and MariaDB Enterprise Backup.The packages are served from `https://dlm.mariadb.com/repo/<token>/mariadb-enterprise-server/<version>/`.

To configure a different release series, or to pin a specific release, use the `--mariadb-server-version` option. To skip this repository, use the `--skip-server` option.

Output an example MariaDB Enterprise Server repository configuration

To output just the MariaDB Enterprise repository configuration to standard output (stdout), do the following:

```
./mariadb_es_repo_setup --token=$token --skip-check-installed --skip-enterprise-tools --skip-maxscale --
verbose
```

> **Note:**
>
> For more verbose output, use the `--verbose` option

You may also want to use the `--os-type`, `--os-version`, and `--arch` options if you are running the script on a machine running a different operating system and/or processor architecture than the machine the configuration will be used on. If you want to specify a specific MariaDB Enterprise version or series, then also use the `--mariadb-server-version` option.

Descriptions for all of these options are found in the Options section, below.

MariaDB Enterprise MaxScale Repository

> **Warning:**
>
> **Note**
>
> MaxScale Enterprise releases, as of 2025-12-09, are now signed with a new key. The `mariadb_repo_setup` and `mariadb_es_repo_setup` scripts have been updated to automatically install the new key, but for existing repositories, you'll need to do the following.
>
> On Debian and Ubuntu:
>
> ```
> curl -LsSO https://supplychain.mariadb.com/mariadb-keyring-2025.gpg
> sudo mv mariadb-keyring-2025.gpg /etc/apt/trusted.gpg.d/
> sudo apt update
> ```
>
> On RHEL & friends:
>
> ```
> sudo rpm --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY-2025
> ```

The **MariaDB Enterprise MaxScale** repository contains MariaDB MaxScale Enterprise packages. The packages are served from `https://dlm.mariadb.com/repo/<token>/maxscale-enterprise/<version>/`.

`mariadb_es_repo_setup` configures the latest stable MariaDB MaxScale Enterprise release series by default. To configure a different version, use the `--mariadb-maxscale-version` option. To skip this repository, use the `--skip-maxscale` option.

MariaDB Enterprise Tools Repository

The **MariaDB Enterprise Tools** repository contains additional tools for use with MariaDB Enterprise. The packages are served from `https://dlm.mariadb.com/repo/<token>/enterprise-tools/<version>/`.

By default, the script configures the latest version of the Enterprise Tools repository. In most cases, you should not change this. However, the option exists to configure a different version. To do so use the `--mariadb-enterprise-tools-version` option. To skip this repository, use the `--skip-enterprise-tools` option.

The MariaDB Enterprise Unsupported Repository

In addition to its default repositories, the `mariadb_es_repo_setup` script can configure a **MariaDB Enterprise Server Unsupported** repository. This repository contains unsupported storage engines and other supplemental packages, such as the CONNECT storage engine.

The Unsupported repository is *not* configured by default. To include it, add the `--include-unsupported` option when you run the script:

```
sudo ./mariadb_es_repo_setup --token="${token}" --include-unsupported --apply
```

Once the repository is configured, you can install its packages using your platform's package manager, as described in Installing Packages With the MariaDB Package Repository.

> **Warning:**
>
> Packages in the Unsupported repository are not covered by MariaDB Enterprise support. Only install them if you understand the implications.

▶ MariaDB Community Repositories

Supported Distributions

The MariaDB Package Repository setup scripts are designed for Linux distributions that meet MariaDB's current platform support policy. Supported platforms may vary over time and can differ across different MariaDB release series.

For a comprehensive and current list of supported platforms, refer to:

- MariDB Engineering Policy
- The MariaDB Downloads page for your specific version

If the setup script does not support your distribution, you can install MariaDB using the MariaDB Foundation's Repository Configuration Tool or check your distribution's native repositories for MariaDB packages.

Options

Using Options with Curl One-line usage

If you are running the script by piping the curl command to bash and you want to provide options to the script, you must tell it to expect them by executing bash with the options `-s --`, for example, to run the script with the `--help` option:

FOR MARIADB_ES_REPO_SETUP

```
curl -LsS https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup | bash -s -- --token=
<token> --help
```

FOR MARIADB_REPO_SETUP

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --help
```

Full List of Options

Option	Description
`--apply`	`mariadb_es_repo_setup` only. Write the repository configuration to the appropriate file, import the GPG public keys used by the repositories, and update the package cache. The default behavior of `mariadb_es_repo_setup` is to output the repository configuration to stdout. See –apply and –write-to-stdout for more information on this option
`--arch=`	Override detection of the CPU architecture. Acceptable values are `x86_64`, `aarch64`, `amd64`, and `arm64`. If you use this option, the script skips its own CPU architecture detection.
`--help`	Display a usage message and exit
`--include-tools`	Include the 'Tools' repository. This repository is no longer configured by default, so use this option to add it.
`--include-unsupported`	`mariadb_es_repo_setup` only. Include the 'Unsupported' repository, which contains unsupported storage engines (such as the CONNECT engine) and other supplemental packages. This repository is not configured by default. See The Unsupported Repository for more information on this option
`--list`	On Debian and Ubuntu, write the older one-line `/etc/apt/sources.list.d/mariadb.list` format instead of the default Deb822 `mariadb.sources` format
`--mariadb-server-version=`	Override the default MariaDB Server version. See –mariadb-server-version for more information on this option
`--mariadb-maxscale-version=`	Override the default MariaDB MaxScale version. See –mariadb-maxscale-version for more information on this option
`--mariadb-enterprise-tools-version=`	`mariadb_es_repo_setup` only. Override the default MariaDB Enterprise Tools version. By default, the script uses the latest version.
`--os-type=`	Override detection of OS type. Acceptable values include `debian`, `ubuntu`, `rhel`, and `sles`. See –ostype and –os-version for more information on this option
`--os-version=`	Override detection of OS version. Acceptable values depend on the OS type you specify, including: `8`, `9`, or `10` for RHEL; `bookworm` or `trixie` for Debian; and `jammy` or `noble` for Ubuntu. See –ostype and –os-version for more information on this option
`--skip-key-import`	Skip importing GPG signing keys, ***not recommended***
`--skip-maxscale`	Skip the 'MaxScale' repository
`--skip-server`	Skip the 'MariaDB Server' repository (either Community or Enterprise depending on the script you are using)
`--skip-tools`	Skip the 'Tools' repository
`--skip-enterprise-tools`	Skip the 'Enterprise Tools" repository (`mariadb_es_repo_setup` only)
`--skip-verify`	Skip verification of MariaDB Server versions. Use with caution, as this can lead to an invalid repository configuration file being created, sometimes useful for testing
`--skip-check-installed`	Skip tests for required prerequisites for this script, useful if generating the config on a different machine
`--skip-eol-check`	Skip tests for versions that are past their EOL date
`--skip-os-eol-check`	Skip tests for operating system versions past the EOL date

Option	Description
`--token`	`mariadb_es_repo_setup` only. Your MariaDB Enterprise Repository token. This is required for `mariadb_es_repo_setup` to work. The token is not required for `mariadb_repo_setup` or for MariaDB Community Server repositories. See Run the Script: mariadb_es_repo_setup for more information.
`--verbose`	`mariadb_es_repo_setup` only. Be more verbose when running by displaying [info] messages about what the script is doing. `mariadb_repo_setup` always runs in verbose mode, so it does not have this option.
`--version`	Output the script version and exit
`--write-to-stdout`	`mariadb_repo_setup` only. Write output to stdout instead of to the OS's repository configuration file. This will also skip importing GPG public keys and updating the package cache on platforms where that behavior exists. See –apply and –write-to-stdout for more information on this option

The `--mariadb-server-version` Option

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB. If a new major GA release occurs and you would like to upgrade to it, then you will need to either manually edit the repository configuration file to point to the new version or run the script again.

The script can also configure your system to install from the repository of a different version of MariaDB by using the `--mariadb-server-version` option.

Usage Example

MARIADB ENTERPRISE SERVER

With `mariadb_es_repo_setup` for MariaDB Enterprise Server, to configure your system to install from the MariaDB Enterprise Server 11.8 repository you would do:

```
./mariadb_es_repo_setup --token=$token --mariadb-server-version="11.8"
```

To specify a specific MariaDB Enterprise Server release, you need to put in the full version number, e.g. for MariaDB Enterprise Server 11.8.5-2:

```
./mariadb_es_repo_setup --token=$token --mariadb-server-version="11.8.5-2"
```

For more details see Pinning the Repository to a Specific Minor Release

MARIADB COMMUNITY SERVER

With mariadb_repo_setup for MariaDB Community Server, the string `mariadb-` has to be prepended to the version number. For example, to configure your system to install from the repository of MariaDB 11.8, that would be:

```
./mariadb_repo_setup --mariadb-server-version="mariadb-11.8"
```

To specify a specific MariaDB Community Server release, you need to put in the full version number, e.g. for MariaDB Community Server 11.8.5:

```
./mariadb_repo_setup --mariadb-server-version="mariadb-11.8.5"
```

For more details see Pinning the Repository to a Specific Minor Release

Current Supported Major Versions

MARIADB ENTERPRISE SERVER

The following MariaDB Enterprise Server versions are currently supported:

- `10.6`
- `11.4`
- `11.8` (default)

MARIADB COMMUNITY SERVER

The following MariaDB Community Server versions are currently supported:

- `mariadb-10.6`
- `mariadb-10.11`
- `mariadb-11.4`
- `mariadb-11.8`
- `mariadb-11.rolling`
- `mariadb-11.rc`
- `mariadb-12.1`
- `mariadb-12.2`
- `mariadb-12.rolling` (default)
- `mariadb-12.rc`

Pinning the Repository to a Specific Minor Release

MARIADB ENTERPRISE SERVER

If you want to pin the repository of a specific minor release, such as MariaDB Enterprise Server 11.8.5-2, then you need to specify the full release version number, e.g. `11.8.5-2`. This may be helpful if you want to avoid automatic upgrades. However, avoiding upgrades is not recommended, since minor maintenance releases may contain important bug fixes and fixes for security vulnerabilities.

> **Note:**
>
> Note: MariaDB Enterprise Server version numbers include a '*release*' suffix that differs from MariaDB Community Server version numbers, e.g. `-2` for MariaDB Enterprise Server `11.8.5-2` whereas the equivalent MariaDB Community Server release is just `11.8.5`. This suffix is required when specifying the full Enterprise Server version number.
>
> To see a list of all MariaDB Enterprise Server releases, see the Enterprise Server - All Releases page. The Version column in the tables on that page list the version numbers of every MariaDB Enterprise Server release.

See the Usage Example - MariaDB Enterprise Server section above for an example of pinning the repository to a specific version.

MARIADB COMMUNITY SERVER

If you want to pin the repository of a specific minor release, such as MariaDB Community Server 11.8.5, then you need to specify the complete release version, e.g. `mariadb-11.8.5`. This may be helpful if you want to avoid upgrades. However, avoiding upgrades is not recommended, since minor maintenance releases may contain important bug fixes and fixes for security vulnerabilities.

> **Note:**
>
> To see a list of all MariaDB Community Server releases, see the Community Server - All Releases page. The Version column in the tables on that page list the version numbers of every MariaDB Community Server release.

> See the Usage Example - MariaDB Community Server section above for an example of pinning the repository to a specific version.

The `--mariadb-maxscale-version` Option

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB MaxScale.

If you would like to pin the repository to a specific version of MariaDB MaxScale, then you will need to either manually edit the repository configuration file to point to the desired version or use the `--mariadb-maxscale-version` option.

For example, to configure your system to install from the repository of MariaDB MaxScale 6.1, that would be:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --mariadb-maxscale-version="6.1"
```

The following MariaDB MaxScale versions are currently supported:

- MaxScale 25.10
- MaxScale 25.01
- MaxScale 24.02
- MaxScale 23.08
- MaxScale 23.02
- MaxScale 22.08

The special identifiers `latest` (for the latest GA release) and `beta` (for the latest beta release) are also supported. By default, the `mariadb_repo_setup` script uses `latest` as the version.

The `--os-type` and `--os-version` Options

If you want to run this script on an unsupported OS that you believe to be package-compatible with an OS that is supported, then you can use the `--os-type` and `--os-version` options to override the script's OS detection. If you use either option, then you must use both options.

The supported values for `--os-type` are:

- `rhel`
- `debian`
- `ubuntu`
- `sles`

If you use a non-supported value, then the script will fail, just as it would fail if you ran the script on an unsupported OS.

The supported values for `--os-version` are entirely dependent on the OS type.

For Red Hat Enterprise Linux (RHEL): `8`, `9`, and `10` are valid options.

For Debian and Ubuntu, the version must be specified as the codename of the specific release. For example, Debian 13 must be specified as `trixie`, and Ubuntu 24.04 must be specified as `noble`.

These options can be useful if your distribution is a fork of another distribution. As an example, Pop!_OS 24.04 LTS is based on and is fully compatible with Ubuntu 24.04 LTS (noble). Therefore, if you are using Pop!_OS, then you can configure your system to install from the repository of Ubuntu 24.04 LTS (noble) by specifying `--os-type=ubuntu`` ``--os-version=noble` to the MariaDB Package Repository setup script.

For example, to manually set the `--os-type` and `--os-version` to RHEL 10, you could do:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --os-type=rhel --os-
version=10
```

The `--apply` and `--write-to-stdout` Options

The `mariadb_repo_setup` and `mariadb_es_repo_setup` scripts generally behave the same but there are some key differences. One of the major ones relates to the options `--apply` and `--write-to-stdout`.

The `--apply` option is only for `mariadb_es_repo_setup`. It directs the script to apply the changes to the system, including creating the repository configuration file, importing the repository GPG keys, and updating the package cache. `mariadb_repo_setup` does this by default, so it does not have the `--apply` option and instead has the `--write-to-stdout` option to flip the behavior.

The `--write-to-stdout` option is only for `mariadb_repo_setup`. It will prevent the script from modifying anything on the system. The repository configuration will not be written to the repository configuration file, GPG keys will not be imported, and the package cache will not be updated. Instead, the repository configuration will be printed to standard output (stdout). This allows the configuration to be reviewed, redirected elsewhere, consumed by another script, or used in some other way. `mariadb_es_repo_setup` does this by default, so it does not have the `--write-to-stdout` option, and instead has the `--apply` option to flip the behavior.

The `--write-to-stdout` option automatically enables `--skip-key-import`.

For example:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --write-to-stdout
```

Both scripts will ignore unknown options so it is safe to, for example, always pass `--apply` to both scripts so that their behavior is the same.

Platform-Specific Behavior

Locations of the repository configuration file the scripts will create on various Linux distributions and other tasks the scripts do on those distributions.

RHEL

Platform-Specific Behavior on RHEL and equivalents

On Red Hat Enterprise Linux (RHEL) and equivalents, the MariaDB Package Repository setup script performs the following tasks:

1. Creates a repository configuration file at `/etc/yum.repos.d/mariadb.repo`
2. Imports the GPG public key used to verify the signature of MariaDB software packages with `rpm --import` from `supplychain.mariadb.com`

DEBIAN / UBUNTU

Platform-Specific Behavior on Debian and Ubuntu

On Debian and Ubuntu, the MariaDB Package Repository setup script performs the following tasks:

1. Creates a repository configuration file at `/etc/apt/sources.list.d/mariadb.list`
2. Creates a package preferences file at `/etc/apt/preferences.d/mariadb-enterprise.pref`, which gives packages from MariaDB repositories a higher priority than packages from OS and other repositories, which can help avoid conflicts. It looks like the following:

```
Package: *
Pin: origin downloads.mariadb.com
Pin-Priority: 1000
```

1. Imports the GPG public key used to verify the signature of MariaDB software package
2. Updates the package cache with package definitions from the MariaDB Package Repository with `apt update`

SLES

Platform-Specific Behavior on SLES

On SUSE Linux Enterprise Server (SLES), the MariaDB Package Repository setup script performs the following tasks:

1. Creates a repository configuration file at `/etc/zypp/repos.d/mariadb.repo`
2. Imports the GPG public key used to verify the signature of MariaDB software packages with `rpm --import` from `supplychain.mariadb.com`

Installing Packages With the MariaDB Package Repository

After setting up the MariaDB Package Repository, you can install the software packages in the supported repositories.

RHEL

Installing Packages on RHEL and equivalents

To install MariaDB on Red Hat Enterprise Linux (RHEL) and equivalents, see the instructions in the Installing MariaDB Packages with YUM. For example:

```
sudo dnf install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on Red Hat Enterprise Linux (RHEL) and equivalents, see the instructions at MariaDB MaxScale Installation Guide. For example:

```
sudo dnf install maxscale
```

DEBIAN / UBUNTU

Installing Packages on Debian and Ubuntu

To install MariaDB on Debian and Ubuntu, see the instructions at Installing MariaDB Packages with APT. For example:

```
sudo apt install mariadb-server mariadb-client mariadb-backup
```

To install MariaDB MaxScale on Debian and Ubuntu, see the instructions at MariaDB MaxScale Installation & Configuration. For example:

```
sudo apt install maxscale
```

SLES

Installing Packages on SLES

To install MariaDB on SUSE Linux Enterprise Server (SLES), see the instructions at Installing MariaDB Packages with ZYpp. For example:

```
sudo zypper install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on SUSE Linux Enterprise Server (SLES), see the instructions at MariaDB MaxScale Installation Guide. For example:

```
sudo zypper install maxscale
```

Versions

The version number of each script is a date, which you can find by running the script with the `--version` option, or by opening the script in a text editor and looking at line 4, `version="..."`. The tables below list the released versions of each script and their `sha256sum` checksums.

Note:

For the list of changes made in each version, see the changelogs:

- mariadb_repo_setup Changelog
- mariadb_es_repo_setup Changelog

MARIADB_ES_REPO_SETUP

General Deployment Instructions

See Best Practices.

A guide outlining essential recommendations for stable MariaDB deployments, covering backup strategies, change management, security controls, and pre-production testing.

See Deployment Methods.

Overview of different deployment architectures (single-node, primary/replica) & methods, including manual installation via repositories or tarballs, and automated deployment with tools like Ansible.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Best Practices

These best practices warrant consideration, but are not expected to apply to every business or in every situation. Recommendations here are not mandatory.

General Recommendations

We recommend that you:

- Understand business requirements before deployment.
- Adapt deployment practices to align to business requirements.
- Consider to what extent deployed systems should integrate with existing business systems and practices.

Backups

Addition, removal, and change of database systems are types of production changes. Before undertaking any production changes:

- Perform a backup of existing data and database configurations.
- Establish a plan for data restoration for use in reverting a change.
- Perform a test to confirm your backup is complete and viable.

Irreversible Changes

Installation of new database servers, change of server configuration, migrations, upgrades, and downgrades can produce irreversible changes which may require you to restore from the last good backup.

Changes to data format on disk, including from upgrades and downgrades, are generally irreversible. A fault during the upgrade or downgrade process may corrupt data. Confirm you have a recent, full, complete, and tested backup before any upgrade or downgrade operation.

When System-Versioned temporal data tables are in use, downgrade operations will generally require migration of data between servers or restore from a backup made pre-upgrade.

Full and Complete Backup

Before proceeding with an upgrade, perform a full and complete backup. Confirm successful completion of the backup operation and test the backup.

Business requirements may require you to retain backups made to support upgrade and downgrade operations.

Additional information regarding backing up and restoring MariaDB database products can be found in “Recovery”.

Change Management

Change Management, Automation, Orchestration

Server configuration changes should be done through change management. Accurate records of the time of change and reason for change can enable faster issue diagnosis.

Automation can enable repeatability of change deployment, and can aid Pre-Production and Post-Production testing.

Automation or orchestration can enable repeatability of server deployment, including system provisioning.

Production Controls

Dedicated Servers

Database servers exist to run database server software. Database servers should not also run web server software, act as a file server, or run other workloads.

Understand workload and data isolation requirements before server deployment. Isolation requirements are often defined through business requirements, including:

- Data and application security requirements that trigger isolation of one workload from other workloads.
- Separation of Development and Testing environments from Production environments.

Production Controls

Understand control requirements before server deployment, including records of control implementation needed to support audits.

Control requirements typically follow data:

- Both production and non-production systems may require production-level controls based on the presence of data subject to control.
- Database servers, backup servers, and other systems may require production-level controls based on the presence of data subject to control.

Testing

Servers should be validated before exposure to production workloads and production data.

It may be appropriate to prevent access to an unconfigured server until configured and validated. Load balancer configuration, firewall rules, or database server configuration are often used to prevent unintended traffic to new servers.

Details assessed during Pre-Production validation can include:

- Server capacity, including performance of disk systems
- Server security configuration and hardening
- Tuning for initial data load vs production workloads
- Alignment to business requirements

Updates

MariaDB Product Notifications allow you to keep aware of new releases, including security fixes. Customers can manage MariaDB Product Notifications through the MariaDB Customer Portal.

Additionally, MariaDB Enterprise Server follows an enterprise lifecycle, that provides a predictable release schedule.

Obtaining Support

MariaDB Corporation provides commercial support and services for MariaDB database products.

New customers can contact MariaDB Corporation for more information.

Existing MariaDB Subscription customers can access technical support via the MariaDB Customer Portal as detailed in MariaDB Subscription Services Policy.

Deployment Methods

Overview of Deployment Methods

The most common way users acquire MariaDB is through Linux Distribution Repositories, as many prioritize the stability of native OS packaging. MariaDB's Official Repositories follow closely, favored by those needing the latest features. Containerized deployments (Docker) and Cloud/Managed Services represent a significant and growing portion of the user base, reflecting a shift toward automated and outsourced infrastructure. Finally, a smaller group uses Direct Downloads (Tarballs/MSI) or Source Builds for specialized environments.

Comparison of Installation Methods

Method	Pros	Cons
Linux Distro Repos (deb, rpm, macOS)	High stability; seamless OS integration; managed security updates.	Often contains older versions; slower feature rollout.
MariaDB Repos, Local Repository Mirror	Latest stable releases; direct support for new features.	Requires manual repo setup; potential dependency versioning issues.
Docker / Containers	Excellent isolation; high portability; ideal for microservices.	Networking/storage complexity; requires container expertise.
Cloud / Managed	Minimal maintenance; automated backups/scaling; high availability.	Higher long-term cost; less control over configuration; vendor lock-in.
Windows MSI	GUI-driven; handles service registration and basic security setup.	Limited to Windows; harder to automate at scale than CLI.
Binary Tarballs / Package Tarballs	OS independent; allows multiple versions on one host; no root required.	Manual dependency management; requires manual path configuration.
Source Code	Maximum optimization for hardware; custom feature selection.	Extremely time-consuming; requires compilation expertise.

Customer Download Token

MariaDB Corporation customers can use a Customer Download Token to download MariaDB database products using command-line tools or automation. This page provides instructions on how to retrieve and use the Customer Download Token.

Alternatively, customers can download MariaDB database products using a web browser from the MariaDB Enterprise Download page without a Customer Download Token if they are logged in with their MariaDB ID.

Retrieve Customer Download Token

MariaDB Corporation customers can retrieve their Customer Download Token through the MariaDB Customer Portal.

> **Warning:**
>
> MariaDB Corporation's Customer Download Tokens are customer-specific. Protect the token as you would any security credential.

To retrieve the Customer Download Token for your account:

1. Navigate to the Customer Download Token at the MariaDB Customer Portal.
2. Log in using your MariaDB ID.
3. Copy the Customer Download Token.

Use the Customer Download Token

MariaDB Corporation customers can use their Customer Download Token for multiple operations.

Choose the procedure for your desired operation and substitute your Customer Download Token for `CUSTOMER_DOWNLOAD_TOKEN`:

Operation	Use Case
Configure MariaDB Enterprise Repository	Install MariaDB database products using package managers on CentOS / RHEL (YUM), Debian / Ubuntu (APT), and SLES (ZYpp)
Download Binary Files with CLI or Automation	Download binary files using command-line tools or automation
Log In to MariaDB Enterprise Docker Registry	Deploy using Docker

Configure MariaDB Enterprise Repository

MariaDB Corporation provides the MariaDB Enterprise Repository to install MariaDB database products using package managers on CentOS / RHEL (YUM), Debian / Ubuntu (APT), and SLES (ZYpp).

The MariaDB Enterprise Repository is configured using the `mariadb_es_repo_setup` script, which requires the Customer Download Token to be provided via the `--token` option.

For additional information, see "MariaDB Package Repository Setup and Usage".

Download Binary Files

MariaDB Corporation provides an interface to download binary files using command-line tools or automation.

Binary files can be downloaded using command-line tools or automation from the MariaDB Download interface with the Customer Download Token. The URL is in the following format:

```
https://dlm.mariadb.com/CUSTOMER_DOWNLOAD_TOKEN/FILE
```

Download a binary file using the following procedure:

1. In your web browser, visit the MariaDB Download interface for the specific MariaDB database product:
   - MariaDB Enterprise Server
   - MariaDB MaxScale
2. In your web browser, navigate to the binary file that you would like to download and copy the URL. For example, to download a binary tarball of MariaDB Enterprise Server 10.6.20-16 for RHEL 8 on x86_64, the URL is:\

   ```
   https://dlm.mariadb.com/FILE_ID/mariadb-enterprise-server/10.6.20-16/bintar-rhel-8-x86_64/mariadb-enterprise-10.6.20-16-rhel-8-x86_64.tar.gz
   ```

   `FILE_ID` is an internal identifier that is different for each file.
3. Extract the `FILE` path from the copied URL. For example, to download the file mentioned above, the FILE path is:\

   ```
   FILE_ID/mariadb-enterprise-server/10.6.20-16/bintar-rhel-8-x86_64/mariadb-enterprise-10.6.20-16-rhel-8-x86_64.tar.gz
   ```
4. Use your Customer Download Token and the FILE path to construct your customer-specific URL to download the file using command-line tools or automation.For example, to download the file mentioned above, the customer-specific URL is:\

   ```
   https://dlm.mariadb.com/CUSTOMER_DOWNLOAD_TOKEN/FILE_ID/mariadb-enterprise-server/10.6.20-16/bintar-rhel-8-x86_64/mariadb-enterprise-10.6.20-16-rhel-8-x86_64.tar.gz
   ```
5. Use your customer-specific URL to download the file using command-line tools or automation:For example, to download the file mentioned above using `wget`:

```
wget https://dlm.mariadb.com/CUSTOMER_DOWNLOAD_TOKEN/FILE_ID/mariadb-enterprise-server/10.6.20-16/bintar-rhel-8-x86_64/mariadb-enterprise-10.6.20-16-rhel-8-x86_64.tar.gz
```

or using `curl`:

```
curl -LO https://dlm.mariadb.com/CUSTOMER_DOWNLOAD_TOKEN/FILE_ID/mariadb-enterprise-server/10.6.20-16/bintar-rhel-8-x86_64/mariadb-enterprise-10.6.20-16-rhel-8-x86_64.tar.gz
```

Log in to MariaDB Enterprise Docker Registry

Docker is an open platform for developing, shipping, and running applications that allows you to separate your applications from your infrastructure. MariaDB Corporation provides the MariaDB Enterprise Docker Registry.

The MariaDB Enterprise Docker Registry provides Docker images for MariaDB Enterprise Server. The Docker images for MariaDB Enterprise Server are currently beta maturity, so they are not currently recommended for production.

For additional information, see "Deploy MariaDB Enterprise Server with Docker".

This page is: Copyright © 2026 MariaDB. All rights reserved.

Installing MariaDB Enterprise Server

Installing Enterprise Server

Overview

These instructions detail the deployment of MariaDB Enterprise Server in a Single Standalone Server configuration on a range of supported Operating Systems.

These instructions detail how to deploy a single-node row database, which is suited for a transactional or OLTP workload that does not require high availability (HA). This deployment type is generally for non-production use cases, such as for development and testing.

MariaDB Database Products

These instructions detail the deployment of the following MariaDB database products:

Component	Description
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.

MariaDB Enterprise Server Components

These instructions detail the deployment of the following MariaDB Enterprise Server components:

Component	Description
InnoDB	• It is a general purpose storage engine • It is ACID-compliant • It is performant • It is the transactional component of MariaDB's single stack Hybrid Transactional/Analytical Processing (HTAP) solution

Term Definitions

Term	Definition
row database	• A database where all columns of each row are stored together • Best suited for transactional and OLTP workloads • Also known as a "row-oriented database"

Installation

MariaDB Corporation provides package repositories for YUM (RHEL, CentOS), APT (Debian, Ubuntu), and ZYpp (SLES).

Install via YUM (CentOS, RHEL, Rocky)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the YUM package repository.

Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.4.
To configure YUM package repositories:

```
$ sudo yum install curl

$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

3. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*
4. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo yum install MariaDB-server MariaDB-backup
```

4. Configure MariaDB.

Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use. See Configuration.

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository.

Pass the version to install using the –mariadb-server-version flag to mariadb_es_repo_setup. The following directions reference

To configure APT package repositories:

```
$ sudo apt install curl

$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"

$ sudo apt update
```

3. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*
4. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup
```

4. Configure MariaDB.

Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use. See Configuration.

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the ZYpp package repository.

Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.4.

To configure ZYpp package repositories:

```
$ sudo zypper install curl

$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup

$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -

$ chmod +x mariadb_es_repo_setup

$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

3. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*
4. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo zypper install MariaDB-server MariaDB-backup
```

4. Configure MariaDB.

Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use. See Configuration.

Configuration

MariaDB Enterprise Server can be configured in the following ways:

- System variables and options can be set in a configuration file (such as /etc/my.cnf). MariaDB Enterprise Server must be restarted to apply changes made to the configuration file.
- System variables and options can be set on the command-line.
- If a system variable supports dynamic changes, then it can be set on-the-fly using the SET statement.

Configuration Files

MariaDB's packages include several bundled configuration files. It is also possible to create custom configuration files.

On RHEL, CentOS, and SLES, MariaDB's packages bundle the following configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`

- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

And on RHEL, CentOS, and SLES, custom configuration files from the following directories are read by default:

- `/etc/my.cnf.d/`

On Debian and Ubuntu, MariaDB's packages bundle the following configuration files:

- `/etc/mysql/my.cnf`
- `/etc/mysql/mariadb.cnf`
- `/etc/mysql/mariadb.conf.d/50-client.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysql-clients.cnf`
- `/etc/mysql/mariadb.conf.d/50-mysqld_safe.cnf`
- `/etc/mysql/mariadb.conf.d/50-server.cnf`
- `/etc/mysql/mariadb.conf.d/60-galera.cnf`
- `/etc/mysql/mariadb.conf.d/mariadb-enterprise.cnf`

And on Debian and Ubuntu, custom configuration files from the following directories are read by default:

- `/etc/mysql/conf.d/`
- `/etc/mysql/mariadb.conf.d/`

Configure MariaDB

Determine which system variables and options you need to configure.

Useful system variables and options for MariaDB Enterprise Server include:

System Variable/Option	Description
datadir	Sets the path to the data directory. MariaDB Enterprise Server writes data files to this directory, including tablespaces, logs, and schemas. Change it to use a non-standard location or to start the Server on a different data directory for testing.
bind_address	Sets the local TCP/IP address on which MariaDB Enterprise Server listens for incoming connections. When testing on a local system, bind the address to the local host at 127.0.0.1 to prevent network access.
port	Sets the port MariaDB Enterprise Server listens on. Use this system variable to use a non-standard port or when running multiple Servers on the same host for testing.
max_connections	Sets the maximum number of simultaneous connections MariaDB Enterprise Server allows.
thread_handling	Sets how MariaDB Enterprise Server handles threads for client connections.
log_error	Sets the file name for the error log.
innodb_buffer_pool_size	Sets the amount of memory InnoDB reserves for the Buffer Pool.
innodb_log_file_size	Sets the size for each Redo Log file and innodb_log_files_in_group sets the number of Redo Log files used by InnoDB.
innodb_io_capacity	Sets the maximum number of I/O operations per second that InnoDB can use.

2. Choose a configuration file in which to configure your system variables and options.

It is not recommended to make custom changes to one of the bundled configuration files. Instead, it is recommended to create a custom configuration file in one of the included directories. Configuration files in included directories are read in alphabetical order. If you want your custom configuration file to override the bundled configuration files, then it is a good idea to prefix the custom configuration file's name with a string that will be sorted last, such as `z-`.

- On RHEL, CentOS, and SLES, a good custom configuration file would be: `/etc/my.cnf.d/z-custom-my.cnf`
- On Debian and Ubuntu, a good custom configuration file would be: `/etc/mysql/mariadb.conf.d/z-custom-my.cnf`

3. Set your system variables and options in the configuration file.

They need to be set in a group that will be read by mariadbd, such as [mariadb] or [server].

For example:

```
[mariadb]
log_error                = mariadbd.err
innodb_buffer_pool_size   = 1G
```

Start the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use systemd (most supported OSes), you can manage the Server process using the systemctl command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Test MariaDB Enterprise Server

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using mariadb Client using the `root@localhost` user account:

```
$ sudo mariadb

Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 38
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

Installing Primary/Replica

Overview

Software Version	Diagram	Features
• Enterprise Server 10.4 • Enterprise Server 10.5 • Enterprise Server 10.6 • Enterprise Server 11.4		**MariaDB Replication** • Highly available • Asynchronous or semi-synchronous replication • Automatic failover via MaxScale • Manual provisioning of new nodes from backup • Scales reads via MaxScale • Enterprise Server 10.3+, MaxScale 2.5+

This procedure describes the deployment of the **Primary/Replica topology** with MariaDB Enterprise Server and MariaDB MaxScale.

Primary/Replica topology provides read scalability and fault tolerance through asynchronous or semi-synchronous single-primary replication.

This procedure has 7 steps, which are executed in sequence.

MariaDB products can be deployed in many different topologies to suit specific use cases. The Primary/Replica topology can be deployed on its own or integrated with MariaDB Enterprise Cluster.

This procedure represents basic product capability with 3 Enterprise Server nodes and 1 MaxScale node.

This page provides an overview of the topology, requirements, and deployment procedure.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Install MariaDB Enterprise Server
Step 2	Start and Configure MariaDB Enterprise Server on Primary Server
Step 3	Start and Configure MariaDB Enterprise Server on Replica Servers
Step 4	Test MariaDB Enterprise Server
Step 5	Install MariaDB MaxScale
Step 6	Start and Configure MariaDB MaxScale
Step 7	Test MariaDB MaxScale

Components

The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.
MariaDB MaxScale	Database proxy that extends the availability, scalability, and security of MariaDB Enterprise Servers

MariaDB Enterprise Server Components

Component	Description
InnoDB	

MariaDB MaxScale Components

Component	Description
Listener	Listens for client connections to MaxScale, then passes them to the router service associated with the listener
MariaDB Monitor	Tracks changes in the state of MariaDB Enterprise Servers.
Read Connection Router	Routes connections from the listener to any available Enterprise Server node
Read/Write Split Router	Routes read operations from the listener to any available Enterprise Server node, and routes write operations from the listener to a specific server operating as the primary server
Server Module	Connection configuration in MaxScale to an Enterprise Server node

Topology

Primary/Replica topology provides read scalability and fault tolerance through asynchronous or semi-synchronous single-primary replication of MariaDB Enterprise Server 11.4

The Primary/Replica topology consists of:

- 1 or more MaxScale nodes
- 1 Enterprise Server node operating as the primary server
- 2 or more Enterprise Server nodes operating as replica servers.

The MaxScale nodes:

- Monitor the health and availability of the Enterprise Server nodes
- Route queries to Enterprise Server nodes using Read/Write Split (`readwritesplit`) and Read Connection (`readconnroute`) routers.
- Promote replica servers in the event that the primary server fails.

The Enterprise Server node is operating as the primary server:

- Receives write queries from MaxScale, logging them to the Binary Log
- Provides Binary Logs to replica servers for replication

The Enterprise Server nodes are operating as replica servers:

- Receive read queries from MaxScale
- Replicate writes asynchronously or semi-synchronously from the primary server

Requirements

These requirements are for the Primary/Replica topology when deployed with MariaDB Enterprise Server 11.4 and MariaDB MaxScale 25.01.

- Operating System
- System User Accounts

Operating System

In alignment to the enterprise lifecycle, the Primary/Replica topology with MariaDB Enterprise Server 11.4 and MariaDB MaxScale 25.01 is provided for:

- AlmaLinux 8 (x86_64, ARM64)
- AlmaLinux 9 (x86_64, ARM64)
- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)

- Microsoft Windows (x86_64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, PPC64LE, ARM64)
- Red Hat UBI 8 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- SUSE Linux Enterprise Server 15 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

System User Accounts

User Account	Purpose
`maxscale`	MaxScale process owner
`mysql`	Enterprise Server process owner

- MariaDB Enterprise Server Logs
- MaxScale Configuration Management
- MaxScale Service Management

MariaDB Enterprise Server Configuration Management

Method	Description
Configuration File	Configuration files (such as `/etc/my.cnf`) can be used to set system-variables and options. The server must be restarted to apply changes made to configuration files.
Command-line	The server can be started with command-line options that set system-variables and options.
SQL	Users can set system-variables that support dynamic changes on-the-fly using the SET statement.

MariaDB Enterprise Server packages are configured to read configuration files from different paths, depending on the operating system. Making custom changes to Enterprise Server default configuration files is not recommended because custom changes may be overwritten by other default configuration files that are loaded later.

To ensure that your custom changes will be read last, create a custom configuration file with the `z-` prefix in one of the include directories.

Distribution	Example Configuration File Path
• CentOS • Red Hat Enterprise Linux (RHEL) • SUSE Linux Enterprise Server (SLES)	`/etc/my.cnf.d/z-custom-mariadb.cnf`
• Debian • Ubuntu	`/etc/mysql/mariadb.conf.d/z-custom-mariadb.cnf`

MariaDB Enterprise Server Service Management

The `systemctl` command is used to start and stop the MariaDB Enterprise Server service.

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

For additional information, see "Starting and Stopping MariaDB".

MariaDB Enterprise Server Logs

MariaDB Enterprise Server produces log data that can be helpful in problem diagnosis.

Log filenames and locations may be overridden in the server configuration. The default location of logs is the data directory. The data directory is specified by the datadir system variable.

Log	System Variable/Option	Default Filename
MariaDB Error Log	log_error	`<hostname>.err`
MariaDB Enterprise Audit Log	server_audit_file_path	`server_audit.log`
Slow Query Log	slow_query_log_file	`<hostname>-slow.log`
General Query Log	general_log_file	`<hostname>.log`
Binary Log	log_bin	`<hostname>-bin`

MaxScale Configuration Management

MaxScale can be configured using several methods. These methods make use of MaxScale's REST API.

Method	Benefits
MaxCtrl	Command-line utility to perform administrative tasks through the REST API. See MaxCtrl Commands.
MaxGUI	MaxGUI is a graphical utility that can perform administrative tasks through the REST API.
REST API	The REST API can be used directly. For example, the `curl` utility could be used to make REST API calls from the command-line. Many programming languages also have libraries to interact with REST APIs.

The procedure on these pages configures MaxScale using MaxCtrl.

MaxScale Service Management

The `systemctl` command is used to start and stop the MaxScale service.

Operation	Command
Start	`sudo systemctl start maxscale`
Stop	`sudo systemctl stop maxscale`
Restart	`sudo systemctl restart maxscale`
Enable during startup	`sudo systemctl enable maxscale`
Disable during startup	`sudo systemctl disable maxscale`

Operation	Command
Status	`sudo systemctl status maxscale`

For additional information, see “Starting and Stopping MariaDB”.

Next Step

Navigation in the procedure “Deploy Primary/Replica Topology”:

- Next: Step 1: Install MariaDB Enterprise Server

Enterprise Server with ColumnStore (Local Storage)

This procedure describes the deployment of the **Single-Node Enterprise ColumnStore** topology with Local storage.

MariaDB Enterprise ColumnStore 23.10 is a columnar storage engine for MariaDB Enterprise Server 10.6. Enterprise ColumnStore is best suited for Online Analytical Processing (OLAP) workloads.

This procedure has 5 steps, which are executed in sequence.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Prepare System for Enterprise ColumnStore
Step 2	Install Enterprise ColumnStore
Step 3	Start and Configure Enterprise ColumnStore 23.10
Step 4	Test Enterprise ColumnStore
Step 5	Bulk Import Data to Enterprise ColumnStore

Support

Customers can obtain support by submitting a support case.

Components

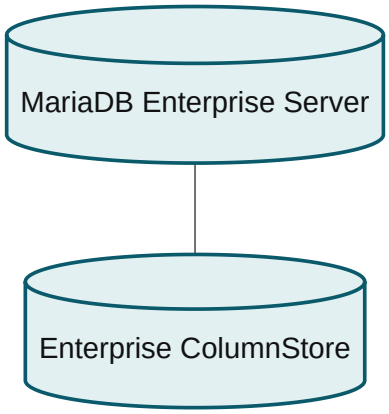
The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.

MariaDB Enterprise Server Components

Component	Description
MariaDB Enterprise ColumnStore	• Columnar Storage Engine • Optimized for Online Analytical Processing (OLAP) workloads

Topology



A single Enterprise Server node runs ColumnStore on local storage.

The Single-Node Enterprise ColumnStore topology provides support for Online Analytical Processing (OLAP) workloads to MariaDB Enterprise Server.

The Enterprise ColumnStore node:

- Receives queries from the application
- Executes queries
- Uses the local disk for storage.

High Availability

Single-Node Enterprise ColumnStore does not provide high availability (HA) for Online Analytical Processing (OLAP). If you would like to deploy Enterprise ColumnStore with high availability, see Enterprise ColumnStore with Shared Local storage.

Requirements

These requirements are for the Single-Node Enterprise ColumnStore, when deployed with MariaDB Enterprise Server 10.6 and MariaDB Enterprise ColumnStore 23.10.

Operating System

- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

Minimum Hardware Requirements

MariaDB Enterprise ColumnStore's minimum hardware requirements are not intended for production environments, but the minimum hardware requirements can be appropriate for development and test environments. For production environments, see the recommended hardware requirements instead.

The minimum hardware requirements are:

Component	CPU	Memory
Enterprise ColumnStore node	4+ cores	16+ GB

MariaDB Enterprise ColumnStore will refuse to start if the system has less than 3 GB of memory.

If Enterprise ColumnStore is started on a system with less memory, the following error message will be written to the ColumnStore system log called `crit.log`:

```
Apr 30 21:54:35 a1ebc96a2519 PrimProc[1004]: 35.668435 |0|0|0| C 28 CAL0000: Error total memory available
is less than 3GB.
```

And the following error message will be raised to the client:

```
ERROR 1815 (HY000): Internal error: System is not ready yet. Please try again.
```

Recommended Hardware Requirements

MariaDB Enterprise ColumnStore's recommended hardware requirements are intended for production analytics.

The recommended hardware requirements are:

Component	CPU	Memory
Enterprise ColumnStore node	64+ cores	128+ GB

Quick Reference

MariaDB Enterprise Server Configuration Management

Enterprise Server with ColumnStore (Object Storage)

Overview

This procedure describes the deployment of the Single-Node Enterprise ColumnStore topology with Object storage.

MariaDB Enterprise ColumnStore 23.10 is a columnar storage engine for MariaDB Enterprise Server and Enterprise ColumnStore is best suited for Online Analytical Processing (OLAP) workloads.

This procedure has 5 steps, which are executed in sequence.

This page provides an overview of the topology, requirements, and deployment procedures.

Please read and understand this procedure before executing.

Procedure Steps

Step	Description
Step 1	Prepare System for Enterprise ColumnStore
Step 2	Install Enterprise ColumnStore
Step 3	Start and Configure Enterprise ColumnStore
Step 4	Test Enterprise ColumnStore
Step 5	Bulk Import Data to Enterprise ColumnStore

Support

Customers can obtain support by submitting a support case.

Components

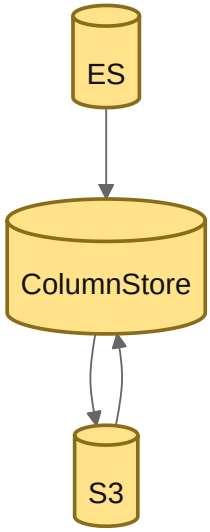
The following components are deployed during this procedure:

Component	Function
MariaDB Enterprise Server	Modern SQL RDBMS with high availability, pluggable storage engines, hot online backups, and audit logging.

MariaDB Enterprise Server Components

Component	Description
MariaDB Enterprise ColumnStore	• Columnar Storage Engine • Optimized for Online Analytical Processing (OLAP) workloads • S3-compatible object storage

Topology



A single MariaDB Enterprise Server node running the Enterprise ColumnStore engine, which reads and writes data to and from S3-compatible object storage.

The Single-Node Enterprise ColumnStore topology provides support for Online Analytical Processing (OLAP) workloads to MariaDB Enterprise Server.

The Enterprise ColumnStore node:

- Receives queries from the application
- Executes queries
- Use S3-compatible object storage for data

High Availability

Single-Node Enterprise ColumnStore does not provide high availability (HA) for Online Analytical Processing (OLAP). If you would like to deploy Enterprise ColumnStore with high availability, see Enterprise ColumnStore with Object storage.

Requirements

These requirements are for the Single-Node Enterprise ColumnStore, when deployed with MariaDB Enterprise Server and MariaDB Enterprise ColumnStore.

Operating System

- Debian 11 (x86_64, ARM64)
- Debian 12 (x86_64, ARM64)
- Red Hat Enterprise Linux 8 (x86_64, ARM64)
- Red Hat Enterprise Linux 9 (x86_64, PPC64LE, ARM64)

- Red Hat UBI 8 (x86_64, ARM64)
- Rocky Linux 8 (x86_64, ARM64)
- Rocky Linux 9 (x86_64, ARM64)
- Ubuntu 20.04 LTS (x86_64, ARM64)
- Ubuntu 22.04 LTS (x86_64, ARM64)
- Ubuntu 24.04 LTS (x86_64, ARM64)

Minimum Hardware Requirements

MariaDB Enterprise ColumnStore's minimum hardware requirements are not intended for production environments, but the minimum hardware requirements can be appropriate for development and test environments. For production environments, see the recommended hardware requirements instead.

The minimum hardware requirements are:

Component	CPU	Memory
Enterprise ColumnStore node	4+ cores	16+ GB

MariaDB Enterprise ColumnStore will refuse to start if the system has less than 3 GB of memory.

If Enterprise ColumnStore is started on a system with less memory, the following error message will be written to the ColumnStore system log called `crit.log`:

```
Apr 30 21:54:35 a1ebc96a2519 PrimProc[1004]: 35.668435 |0|0|0| C 28 CAL0000: Error total memory available
is less than 3GB.
```

And the following error message will be raised to the client:

```
ERROR 1815 (HY000): Internal error: System is not ready yet. Please try again.
```

Recommended Hardware Requirements

MariaDB Enterprise ColumnStore's recommended hardware requirements are intended for production analytics.

The recommended hardware requirements are:

Component	CPU	Memory
Enterprise ColumnStore node	64+ cores	128+ GB

Storage Requirements

Single-node Enterprise ColumnStore with Object Storage requires the following storage type:

Storage Type	Description
S3-Compatible Object Storage	Single-node Enterprise ColumnStore with Object Storage uses S3-compatible object storage to store data.

S3-Compatible Object Storage Requirements

Single-node Enterprise ColumnStore with Object Storage uses S3-compatible object storage to store data.

Many S3-compatible object storage services exist. MariaDB Corporation cannot make guarantees about all S3-compatible object storage services, because different services provide different functionality.

For the preferred S3-compatible object storage providers that provide cloud and hardware solutions, see the following sections:

- Cloud
- Hardware

The use of non-cloud and non-hardware providers is at your own risk.

If you have any questions about using specific S3-compatible object storage with MariaDB Enterprise ColumnStore, contact us.

Preferred Object Storage Providers: Cloud

- Amazon Web Services (AWS) S3
- Google Cloud Storage
- Azure Storage
- Alibaba Cloud Object Storage Service

Preferred Object Storage Providers: Hardware

- Cloudian HyperStore
- Dell EMC
- Seagate Lyve Rack
- Quantum ActiveScale
- IBM Cloud Object Storage

MariaDB ID Sign Up

A MariaDB ID is a free account that provides:

- Customer access to MariaDB database product downloads

Create A MariaDB ID

You can register for a MariaDB ID with a social login or a traditional email/password.

Register for a MariaDB ID account.

Create a MariaDB ID using one of the following Single sign-on methods:

- Sign up using your Google Account
- Sign up using your GitHub Account

- Sign up using your LinkedIn Account

Or use your email address:

- Enter your email address and press next.
- Click the reset button. A password link will appear in your email.
- Once you set a new password, the MariaDB account page will appear.

Obtaining Support

MariaDB Corporation provides commercial support and services for MariaDB database products.

To contact us with questions, or if you need assistance:

- If you are able to login to your MariaDB ID, open a support case
- If you do not have a MariaDB ID or are unable to login, contact us
- MariaDB Customer Portal

GPG

The MariaDB project signs their MariaDB packages for Debian, Ubuntu, Fedora, and Red Hat. This page documents information about the keys that we use and have used.

MariaDB Community Server Debian / Ubuntu key

Our MariaDB Community Server repositories for Debian “Sid” and the Ubuntu 16.04 and beyond “Xenial” use the following GPG signing key. As detailed in MDEV-9781, APT 1.2.7 (and later) prefers SHA2 GPG keys and now prints warnings when a repository is signed using a SHA1 key like our previous GPG key. We have created a SHA2 key for use with these.

Information about this key:

- The short Key ID is: `0xC74CD1D8`
- The long Key ID is: `0xF1656F24C74CD1D8`
- The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
- The key can be added on Debian-based systems using the following command:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
```

- Usage of the `apt-key` command is deprecated in the latest versions of Debian and Ubuntu, and the replacement method is to download the keyring file to the `/etc/apt/trusted.gpg.d/` directory. This can be done with the following:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2019.gpg https://supplychain.mariadb.com/mariadb-keyring-2019.gpg
```

Prior to Debian 9 (Stretch), and Debian Unstable (Sid), and Ubuntu 16.04 LTS (Xenial), the id of our GPG public key was `0xcbcb082a1bb943db`. The full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

MariaDB Community Server RPM / Source Keys

> **2023+**
>
> Beginning in 2023 we migrated the key used to sign our `yum/dnf/zypper` repositories and to sign our source code and binary tarballs to the same key we use for Debian and Ubuntu.
>
> Key ID and Fingerprint information is in the MariaDB Community Server Debian/Ubuntu Key section, above.

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

PRE-2023

The GPG Key ID of the MariaDB signing key we used for `yum/dnf/zypper` repositories and to sign our source code tarballs until the end of 2022 was `0xCBCB082A1BB943DB`. The short form of the id is `0x1BB943DB` and the full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

This key was used by the `yum/dnf/zypper` repositories for RedHat, CentOS, Fedora, openSUSE, and SLES.

If you configure the mariadb.org rpm repositories using the repository configuration tool then your package manager will prompt you to import the key the first time you install a package from the repository.

You can also import the key directly using the following command:

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY-2010
```

MariaDB Enterprise GPG Keys

RHEL 7/8/9, DEBIAN 11/12, UBUNTU

Information about the key we use on most platforms for MariaDB Enterprise Server releases:

- The short Key ID is: `0xE3C94F49`
- The long Key ID is: `0xCE1A3DD5E3C94F49`
- The full fingerprint of the key is: `4C47 0FFF EFC4 D3DC 5977 8655 CE1A 3DD5 E3C9 4F49`

On Debian / Ubuntu systems, you can install the keyring containing this key with:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2019.gpg https://supplychain.mariadb.com/mariadb-keyring-2019.gpg
```

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY
```

RHEL 10+ , DEBIAN 13+

For RHEL, AlmaLinux, Rocky, and Oracle Linux 10 and above, and for Debian 13 Trixie and above there are new requirements around GPG keys used to sign packages. For these distributions we have created a stronger GPG key for our Enterprise Server releases.

Information on this key:

- The short Key ID is: `0x8C27D14E`

- The long Key ID is: `0x5D87FACA8C27D14E`
- The full fingerprint of the key is: `BB2A 36F3 6C3B 4D37 3BAC 328A 5D87 FACA 8C27 D14E`

On Debian / Ubuntu systems, you can install the keyring containing this key with:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2025.gpg https://supplychain.mariadb.com/mariadb-keyring-2025.gpg
```

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY-2025
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY-2025
```

MariaDB MaxScale GPG Keys

DEC 2025+

In December 2025, MariaDB MaxScale moved to using the same GPG key used by MariaDB Enterprise Server for RHEL 10 and Debian 13 Trixie.

Information on this key:

- The short Key ID is: `0x8C27D14E`
- The long Key ID is: `0x5D87FACA8C27D14E`
- The full fingerprint of the key is: `BB2A 36F3 6C3B 4D37 3BAC 328A 5D87 FACA 8C27 D14E`

On Debian / Ubuntu systems, you can install the keyring containing this key with:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2025.gpg https://supplychain.mariadb.com/mariadb-keyring-2025.gpg
```

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY-2025
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Enterprise-GPG-KEY-2025
```

PRE DEC 2025

Information on the key used by MaxScale repositories prior to December 2025:

- The short Key ID is: `0xE3C94F49`
- The long Key ID is: `0xCE1A3DD5E3C94F49`
- The full fingerprint of the key is: `4C47 0FFF EFC4 D3DC 5977 8655 CE1A 3DD5 E3C9 4F49`

On Debian / Ubuntu systems, you can install the keyring containing this key with:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2025.gpg https://supplychain.mariadb.com/mariadb-keyring-2025.gpg
```

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-MaxScale-GPG-KEY
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-MaxScale-GPG-KEY
```

Configuring Repositories

See the MariaDB Package Repository Setup and Usage page for details on using the `mariadb_repo_setup` and `mariadb_es_repo_setup` scripts to configure repositories that use these keys.

See the details on configuring MariaDB Foundation repositories that use these keys.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB .deb Files

Installing MariaDB with APT

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant `.deb` packages from MariaDB's repository using apt, aptitude, Ubuntu Software Center, Synaptic Package Manager, or another package manager.

This page walks you through the simple installation steps using `apt`.

Adding the MariaDB APT repository

We currently have APT repositories for the following Linux distributions:

- Debian 11 (Bullseye)
- Debian 12 (Bookworm)
- Debian 13 (Trixie)
- Debian Unstable (Sid)
- Ubuntu 22.04 (Jammy)
- Ubuntu 24.04 (Noble)

Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with `apt`, then you can configure `apt` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use `apt` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and mariadb-backup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for MariaDB MaxScale and a repository for MariaDB Tools, which currently only contains Percona XtraBackup and its dependencies.

See MariaDB Package Repository Setup and Usage for more information.

Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with `apt`, then you can configure `apt` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use `apt-get` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and mariadb-backup. The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.

There are several ways to add the repository.

Executing add-apt-repository

One way to add an `apt` repository is by using the add-apt-repository command. This command will add the repository configuration to `/etc/apt/sources.list`.

For example, if you wanted to use the repository to install MariaDB 10.6 on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add the MariaDB `apt` repository:

```
sudo apt-get install software-properties-common
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.6/ubuntu bionic main'
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Creating a Source List File

Another way to add an `apt` repository is by creating a source list file in `/etc/apt/sources.list.d/`.

For example, if you wanted to use the repository to install MariaDB 10.6 on Ubuntu 18.04 LTS (Bionic), then you could create the `MariaDB.list` file in `/etc/apt/sources.list.d/` with the following contents to add the MariaDB `apt` repository:

```
# MariaDB 10.6 repository list - created 2019-01-27 09:50 UTC
# http://downloads.mariadb.org/mariadb/repositories/
deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.6/ubuntu bionic main
deb-src http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.6/ubuntu bionic main
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Using Ubuntu Software Center

Another way to add an `apt` repository is by using Ubuntu Software Center.

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **Edit** > **Software Sources** or by navigating to **System** > **Administration** > **Software Sources**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can input the repository information provided by the MariaDB Repository Configuration Tool.

See here for more information.

Using Synaptic Package Manager

Another way to add an `apt` repository is by using Synaptic Package Manager.

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **System** > **Administrator** > **Software Sources** or by navigating to **Settings** > **Repositories**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can input the repository information provided by the MariaDB Repository Configuration Tool.

See here for more information.

Pinning the MariaDB Repository to the repository of a Specific Minor Release

If you wish to pin the `apt` repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create an `apt` repository with the URL hard-coded to that specific minor release.

MARIADB CORPORATION REPO SETUP SCRIPTS

If you used MariaDB Corporation's `mariadb_repo_setup` or `mariadb_es_repo_setup` scripts to generate your repository configuration, simply re-run the script and specify the full version number to use with the `--mariadb-server-version` option.

See Pinning the Repository to a Specific Minor Release on the MariaDB Package Repository Setup and Usage page for details.

The full list of MariaDB Enterprise Server releases can be found on the Enterprise Server - All Releases page.

MARIADB FOUNDATION REPO CONFIG TOOL

If you used the MariaDB Foundation's Repository Configuration tool, then you need to update the repository file you created to include the full version number. By default the Foundation's tool configures repositories with just the main series of MariaDB, e.g. `mariadb-11.8`, and to pin to a specific version you need to specify the full version, for example `mariadb-11.8.6`. The full list of MariaDB Community Server releases can be found on the Community Server - All Releases page.

Archives are only of the distros and architectures supported at the time of release. For example, MariaDB Community Server 10.6.21 exists for Ubuntu `bionic`, `focal`, `jammy`, and `kinetic`, and the list of what distributions are available is obtained by looking in the `dists` folder of the 10.6.21 Debian or Ubuntu repositories.

For example, if you wanted to pin your repository to MariaDB Community Server 10.5.9 on Ubuntu 20.04 LTS (Focal), then you would have to first remove any existing MariaDB repository source list file from `/etc/apt/sources.list.d/`. And then you could use the following commands to add the MariaDB `apt-get` repository:

```
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el,s390x] http://archive.mariadb.org/mariadb-10.5.9/repo/ubuntu/ focal main main/debug'
```

Ensure you have the signing key installed.

Ubuntu Xenial and older will need:

```
sudo apt-get install -y apt-transport-https
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Updating the MariaDB APT repository to a New Major Release

MariaDB's `apt` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `apt` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Foundation's Repository Configuration Tool

If you configured `apt` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release in various ways, depending on how you originally added the repository.

Updating a Repository with add-apt-repository

If you added the `apt` repository by using the add-apt-repository command, then you can update the major release that the repository uses by using the add-apt-repository command again.

First, look for the repository string for the old version in `/etc/apt/sources.list`.

And then, you can remove the repository for the old version by executing the add-apt-repository command and providing the `--remove` option. For example, if you wanted to remove a MariaDB 10.6 repository, then you could do so by executing something like the following:

```
sudo add-apt-repository --remove 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.6/ubuntu bionic main'
```

After that, you can add the repository for the new version with the add-apt-repository command. For example, if you wanted to use the repository to install MariaDB 10.6 on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add the MariaDB `apt` repository:

```
sudo apt-get install software-properties-common
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.6/ubuntu bionic main'
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to MariaDB 10.6 and you can upgrade to the new version of MariaDB.

Updating a Source List File

If you added the `apt` repository by creating a source list file in `/etc/apt/sources.list.d/`, then you can update the major release that the repository uses by updating the source list file in-place. For example, if you wanted to change the repository from MariaDB 10.5 to MariaDB 10.6, and if the source list file was at `/etc/apt/sources.list.d/MariaDB.list`, then you could execute the following:

```
sudo sed -i 's/10.5/10.6/' /etc/apt/sources.list.d/MariaDB.list
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to MariaDB 10.6 and you can upgrade to the new version of MariaDB.

Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the `apt` utility to verify the integrity of the packages that

it installs.

For **MariaDB Community Server**, see the MariaDB Community Server Debian / Ubuntu key section of the GPG page for details on how to import the key used by those repositories on your Debian or Ubuntu system.

For **MariaDB Enterprise Server**, see the MariaDB Enterprise GPG Keys section of the GPG page for details on how to import the key used by those repositories on your Debian or Ubuntu system.

> **Note:**
>
> Starting with Debian 9 (Stretch), the dirmngr package needs to be installed before the GPG public key can be imported. To install it, execute: `sudo apt install dirmngr`

Once the GPG public key is imported, you are ready to install packages from the repository.

Installing MariaDB Packages with APT

After the `apt` repository is configured, you can install MariaDB by executing the apt-get command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages with APT

To Install the most common packages, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

To Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server mariadb-server-galera galera-4 mariadb-client libmariadb3 mariadb-backup mariadb-common
```

Installing MariaDB Server with APT

To Install MariaDB Server, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-server
```

Installing MariaDB Galera Cluster with APT

The process to install MariaDB Galera Cluster with the MariaDB `apt-get` repository is practically the same as installing standard MariaDB Server.

Galera Cluster support is included in the standard MariaDB Server packages, so you will need to install the `mariadb-server` package, as you normally would.

You also need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

To install MariaDB Galera Cluster, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

To install MariaDB Galera Cluster, you could execute the following command:

```
sudo apt-get install mariadb-server mariadb-client galera-4
```

MariaDB Galera Cluster also has a separate package that can be installed on arbitrator nodes. The package is called `galera-arbitrator-4`. This package should be installed on whatever node you want to serve as the arbitrator. It can either run on a separate server that is not acting as a cluster node, which is the recommended configuration, or it can run on a server that is also acting as an existing cluster node.

To install the arbitrator package, you could execute the following command:

```
sudo apt install galera-arbitrator-4
```

See Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with APT

MariaDB Connector/C is included as the client library.

To Install the clients and client libraries, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-client libmariadb3
```

Installing mariadb-backup with APT

To install mariadb-backup, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-backup
```

Installing Plugins with APT

Some plugins may also need to be installed.

For example, to install the cracklib_password_check password validation plugin, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-cracklib-password-check
```

Installing Older Versions from the Repository

The MariaDB `apt` repository contains the last few versions of MariaDB. To show what versions are available, use the apt-cache command:

```
sudo apt-cache showpkg mariadb-server
```

There will be a lot of output, but in the “Provides” section at the end of the output you will see the available versions. For example:

```
Package: mariadb-server
Versions:
1:12.1.2+maria~ubu2404 (/var/lib/apt/lists/dlm.mariadb.com_repo_mariadb-
server_12.rolling_repo_ubuntu_dists_noble_main_binary-amd64_Packages)
 Description Language:
 ...<extra-output-snipped>...
 Provides:
1:12.1.2+maria~ubu2404 - virtual-mysql-server (= ) default-mysql-server (= )
1:12.0.2+maria~ubu2404 - virtual-mysql-server (= ) default-mysql-server (= )
1:10.11.13-0ubuntu0.24.04.1 - virtual-mysql-server (= )
1:10.11.7-2ubuntu2 - virtual-mysql-server (= )
```

In the above example there are four versions available, two from the MariaDB repositories, and two from the Ubuntu repositories. The versions from MariaDB have “maria” in the version number, and the versions from Ubuntu have “ubuntu” in the version number.

To install an older version of a package instead of the latest version we just need to specify the package name, an equal sign, and then the complete version number. From the example above, the complete version number for MariaDB 12.0.2 is: `1:12.0.2+maria~ubu2404`

However, when installing an older version of a package, `apt` will automatically choose to install the latest versions of any dependencies, which doesn’t work for dependencies of the `mariadb-server` package like `mariadb-client` and `mariadb-server-core`.

```
sudo apt install mariadb-server=1:12.0.2+maria~ubu2404
```

```
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Some packages could not be installed. This may mean that you have
requested an impossible situation or if you are using the unstable
distribution that some required packages have not yet been created
or been moved out of Incoming.
The following information may help to resolve the situation:

The following packages have unmet dependencies:
 mariadb-client : Breaks: mariadb-server (< 1:12.1.2+maria~ubu2404) but 1:12.0.2+maria~ubu2404 is to be
installed
 mariadb-server-core : Breaks: mariadb-server (< 1:12.1.2+maria~ubu2404) but 1:12.0.2+maria~ubu2404 is to
be installed
E: Unable to correct problems, you have held broken packages.
```

To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all. Therefore, to install the 12.0.2 version of the `mariadb-server` package from this `apt` repository, we would do the following (using a variable to hold the version number, and putting each package on its own line so things are cleaner):

```
ver="1:12.0.2+maria~ubu2404"
sudo apt install \
  mariadb-server=${ver} \
  mariadb-client=${ver} \
  mariadb-server-core=${ver} \
  mariadb-client-core=${ver}
```

For MariaDB Enterprise, version numbers are similar, but have an extra point. For example, MariaDB Enterprise Server 11.8.5-2 for Ubuntu 24.04 Noble has the version number: `1:11.8.5.2+maria~ubu2404` .

The rest of the install and setup process is as normal.

Installing MariaDB with dpkg

While it is not recommended, it is possible to download and install the `.deb` packages manually. However, it is generally recommended to use a package manager like `apt-get`.

A tarball that contains the `.deb` packages can be downloaded from the following URL:

- downloads.mariadb.com

For example, to install the MariaDB 10.6.21 `.deb` packages on Ubuntu 18.04 LTS (Bionic), you could execute the following:

```
sudo apt-get update
sudo apt-get install libdbi-perl libdbd-mysql-perl psmisc libaio1 socat
wget https://downloads.mariadb.com/MariaDB/mariadb-10.6.21/repo/ubuntu/mariadb-10.6.21-ubuntu-bionic-
amd64-debs.tar
tar -xvf mariadb-10.6.21-ubuntu-bionic-amd64-debs.tar
cd mariadb-10.6.21-ubuntu-bionic-amd64-debs/
sudo dpkg --install ./mariadb-common*.deb \
   ./mysql-common*.deb \
   ./mariadb-client*.deb \
   ./libmariadb3*.deb \
   ./libmysqlclient18*.deb
sudo dpkg --install ./mariadb-server*.deb \
   ./mariadb-backup*.deb \
   ./galera-4*.deb
```

After Installation

After the installation is complete, you can start MariaDB.

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

Upgrading to a new version of MariaDB

After updating your repository configuration to move from the repository of one version of MariaDB to a newer version, as per the previous instructions, you will need to upgrade the MariaDB packages, this is done with:

```
sudo apt upgrade mariadb-server
```

Alternatively you can also run the following to installing the new version:

```
sudo apt install mariadb-server galera-4
```

The reason for specifying the `galera-4` package is to ensure the correct updated version of Galera is installed along with the new server version, replacing the versions that were there before.

Available DEB Packages

The available DEB packages depend on the specific MariaDB release series.

Available DEB Packages

For MariaDB, the following DEBs are available:

Package Name	Description
`galera-4`	The WSREP provider for Galera 4.
`libmariadb3`	Dynamic client libraries.
`libmariadb-dev`	Development headers and static libraries.
`libmariadbclient18`	Virtual package to satisfy external depends

Package Name	Description
`libmysqlclient18`	Virtual package to satisfy external depends
`mariadb-backup`	mariadb-backup
`mariadb-client`	Client tools like mariadb CLI, mariadb-dump, and others.
`mariadb-client-core`	Core client tools
`mariadb-common`	Character set files and /etc/my.cnf
`mariadb-plugin-connect`	The CONNECT storage engine.
`mariadb-plugin-cracklib-password-check`	The cracklib_password_check password validation plugin.
`mariadb-plugin-gssapi-client`	The client-side component of the gssapi authentication plugin.
`mariadb-plugin-gssapi-server`	The server-side component of the gssapi authentication plugin.
`mariadb-plugin-rocksdb`	The MyRocks storage engine.
`mariadb-plugin-spider`	The SPIDER storage engine.
`mariadb-server`	The server and server tools, like myisamchk and mariadb-hotcopy are here.
`mariadb-server-galera`	Required for MariaDB Cluster (Galera) functionality. Includes cluster-specific scripts, systemd bootstrap logic, and the `wsrep_info` plugin.
`mariadb-server-core`	The core server.
`mariadb-test`	mysql-client-test executable, and mysql-test framework with the tests.
`mariadb-test-data`	MariaDB database regression test suite - data files

Actions Performed by DEB Packages

Users and Groups Created

When the `mariadb-server` DEB package is installed, it will create a user and group named `mysql`, if they do not already exist.

About the MariaDB RPM Files

Available RPM Packages

The available RPM packages depend on the specific MariaDB release series.

List of RPM Packages in MariaDB

ENTERPRISE SERVER

The following RPMs are in MariaDB Enterprise Server 11.8:

Package Name	Description
`galera-4`	The WSREP provider for Galera 4
`galera-4-debuginfo`	Debuginfo for `galera-4`
`MariaDB-backup`	mariadb-backup is a command-line utility for creating consistent and reliable backups of MariaDB databases, supporting full and incremental backup options
`MariaDB-backup-debuginfo`	Debuginfo for `mariadb-backup`
`MariaDB-client`	Client tools like mariadb CLI, `mariadb-dump`, and others
`MariaDB-client-compat`	Symbolic links from old MySQL tool names to MariaDB, like `mysqladmin` → `mariadb-admin` or `mysql` → `mariadb`. Good to have if you are using MySQL tool names in your scripts
`MariaDB-client-debuginfo`	Debuginfo for client tools like mariadb CLI, `mariadb-dump`, and others
`MariaDB-columnstore-cmapi`	MariaDB ColumnStore cluster management API (CMAPI) and command line tool

Package Name	Description
`MariaDB-columnstore-engine`	The MariaDB ColumnStore storage engine
`MariaDB-columnstore-engine-debuginfo`	Debuginfo for `MariaDB-columnstore-engine`
`MariaDB-common`	Character set files and `/etc/my.cnf`
`MariaDB-common-debuginfo`	Debuginfo for character set files and `/etc/my.cnf`
`MariaDB-cracklib-password-check`	The `cracklib_password_check` password validation plugin
`MariaDB-cracklib-password-check-debuginfo`	Debuginfo for the `cracklib_password_check` password validation plugin
`MariaDB-devel`	Development headers and static libraries
`MariaDB-devel-debuginfo`	Debuginfo for development headers and static libraries
`MariaDB-gssapi-server`	The gssapi authentication plugin
`MariaDB-gssapi-server-debuginfo`	Debuginfo for the gssapi authentication plugin
`MariaDB-hashicorp-key-management`	Encryption plugin that uses Hashicorp Vault for storing encryption keys for MariaDB Data-at-Rest encryption
`MariaDB-hashicorp-key-management-debuginfo`	Debuginfo for `MariaDB-hashicorp-key-management`
`MariaDB-provider-bzip2`	BZip2 compression support in the server and storage engines
`MariaDB-provider-bzip2-debuginfo`	Debuginfo for `MariaDB-provider-bzip2`
`MariaDB-provider-lz4`	LZ4 compression support in the server and storage engines
`MariaDB-provider-lz4-debuginfo`	Debuginfo for `MariaDB-provider-lz4`
`MariaDB-provider-lzma`	LZMA compression support in the server and storage engines
`MariaDB-provider-lzma-debuginfo`	Debuginfo for `MariaDB-provider-lzma`
`MariaDB-provider-lzo`	LZO compression support in the server and storage engines
`MariaDB-provider-lzo-debuginfo`	Debuginfo for `MariaDB-provider-lzo`
`MariaDB-provider-snappy`	Snappy compression support in the server and storage engines
`MariaDB-provider-snappy-debuginfo`	Debuginfo for `MariaDB-provider-snappy`
`MariaDB-rocksdb-engine`	The MyRocks storage engine
`MariaDB-rocksdb-engine-debuginfo`	Debuginfo for the MyRocks storage engine
`MariaDB-s3-engine`	The S3 storage engine, which allows one to archive MariaDB tables in Amazon S3 (or any third-party public or private cloud that implements S3 API), but still have them accessible in MariaDB in read-only mode

Package Name	Description
`MariaDB-s3-engine-debuginfo`	Debuginfo for the S3 storage engine
`MariaDB-server`	The server and server tools, like `myisamchk` and `mariadb-hotcopy` are here
`MariaDB-server-compat`	Symbolic links from old MySQL server executable names to MariaDB, like `mysqld` -> `mariadbd` or `mysql_install_db` -> `mariadb-install-db`. Good to have if you are using MySQL tool names in your scripts
`MariaDB-server-debuginfo`	Debuginfo for the server and server tools, like `myisamchk` and `mariadb-hotcopy` are here
`MariaDB-shared`	Dynamic client libraries
`MariaDB-shared-debuginfo`	Debuginfo for dynamic client libraries
`MariaDB-spider-engine`	The Spider storage engine
`MariaDB-spider-engine-debuginfo`	Debuginfo for the Spider storage engine

Additionally, the following RPMs are available in the MariaDB Enterprise Unsupported repository:

Package Name	Description
`MariaDB-connect-engine`	The CONNECT storage engine
`MariaDB-connect-engine-debuginfo`	Debuginfo for the CONNECT storage engine
`MariaDB-connect-engine-jdbc`	Connect storage engine JDBC interface used to interact with external DBMS via Java connector
`MariaDB-test`	`mysql-client-test` executable, and mysql-test framework with the tests
`MariaDB-test-debuginfo`	Debuginfo for `MariaDB-test`

COMMUNITY SERVER

The following RPMs are in MariaDB Community Server 12.3:

Package Name	Description
`galera-4`	The WSREP provider for Galera 4
`galera-4-debuginfo`	Debuginfo for `galera-4`
`galera-4-debugsource`	Debug sources for package `galera-4`
`MariaDB-backup`	mariadb-backup is a command-line utility for creating consistent and reliable backups of MariaDB databases, supporting full and incremental backup options
`MariaDB-backup-debuginfo`	Debuginfo for `mariadb-backup`
`MariaDB-client`	Client tools like mariadb CLI, `mariadb-dump`, and others
`MariaDB-client-compat`	Symbolic links from old MySQL tool names to MariaDB, like `mysqladmin` -> `mariadb-admin` or `mysql` -> `mariadb`. Good to have if you are using MySQL tool names in your scripts
`MariaDB-client-debuginfo`	Debuginfo for client tools like mariadb CLI, `mariadb-dump`, and others
`MariaDB-columnstore-engine`	The MariaDB ColumnStore storage engine
`MariaDB-columnstore-engine-debuginfo`	Debuginfo for `MariaDB-columnstore-engine`
`MariaDB-common`	Character set files and `/etc/my.cnf`

Package Name	Description
`MariaDB-common-debuginfo`	Debuginfo for character set files and `/etc/my.cnf`
`MariaDB-connect-engine`	The CONNECT storage engine
`MariaDB-connect-engine-debuginfo`	Debuginfo for the CONNECT storage engine
`MariaDB-connect-engine-jdbc`	Connect storage engine JDBC interface used to interact with external DBMS via Java connector
`MariaDB-cracklib-password-check`	The `cracklib_password_check` password validation plugin
`MariaDB-cracklib-password-check-debuginfo`	Debuginfo for the `cracklib_password_check` password validation plugin
`MariaDB-devel`	Development headers and static libraries
`MariaDB-devel-debuginfo`	Debuginfo for development headers and static libraries
`MariaDB-gssapi-server`	The gssapi authentication plugin
`MariaDB-gssapi-server-debuginfo`	Debuginfo for the gssapi authentication plugin
`MariaDB-hashicorp-key-management`	Encryption plugin that uses Hashicorp Vault for storing encryption keys for MariaDB Data-at-Rest encryption
`MariaDB-hashicorp-key-management-debuginfo`	Debuginfo for `MariaDB-hashicorp-key-management`
`MariaDB-oqgraph-engine`	The Open Query GRAPH computation engine, or OQGRAPH, storage engine
`MariaDB-oqgraph-engine-debuginfo`	Debuginfo for the OQGRAPH storage engine
`MariaDB-provider-bzip2`	BZip2 compression support in the server and storage engines
`MariaDB-provider-bzip2-debuginfo`	Debuginfo for `MariaDB-provider-bzip2`
`MariaDB-provider-lz4`	LZ4 compression support in the server and storage engines
`MariaDB-provider-lz4-debuginfo`	Debuginfo for `MariaDB-provider-lz4`
`MariaDB-provider-lzma`	LZMA compression support in the server and storage engines
`MariaDB-provider-lzma-debuginfo`	Debuginfo for `MariaDB-provider-lzma`
`MariaDB-provider-lzo`	LZO compression support in the server and storage engines
`MariaDB-provider-lzo-debuginfo`	Debuginfo for `MariaDB-provider-lzo`
`MariaDB-provider-snappy`	Snappy compression support in the server and storage engines
`MariaDB-provider-snappy-debuginfo`	Debuginfo for `MariaDB-provider-snappy`

Package Name	Description
`MariaDB-rocksdb-engine`	The MyRocks storage engine
`MariaDB-rocksdb-engine-debuginfo`	Debuginfo for the MyRocks storage engine
`MariaDB-s3-engine`	The S3 storage engine, which allows one to archive MariaDB tables in Amazon S3 (or any third-party public or private cloud that implements S3 API), but still have them accessible in MariaDB in read-only mode
`MariaDB-s3-engine-debuginfo`	Debuginfo for the S3 storage engine
`MariaDB-server_galera`	Provides scripts and plugins required for Galera Cluster operation. Decoupled from the base server package starting in 12.3
`MariaDB-server`	The server and server tools, like `myisamchk` and `mariadb-hotcopy` are here
`MariaDB-server-compat`	Symbolic links from old MySQL server executable names to MariaDB, like `mysqld` -> `mariadbd` or `mysql_install_db` -> `mariadb-install-db`. Good to have if you are using MySQL tool names in your scripts
`MariaDB-server-debuginfo`	Debuginfo for the server and server tools, like `myisamchk` and `mariadb-hotcopy` are here
`MariaDB-shared`	Dynamic client libraries
`MariaDB-shared-debuginfo`	Debuginfo for dynamic client libraries
`MariaDB-test`	`mysql-client-test` executable, and mysql-test framework with the tests
`MariaDB-test-debuginfo`	Debuginfo for `MariaDB-test`

Removed RPM Packages

Occasionally, RPM packages are removed from MariaDB. This could be because they are no longer needed, or because they were for features or storage engines that have been removed from MariaDB.

Some examples of removed RPMs are:

Package Name	Description
MariaDB-compat	Old shared client libraries, removed in MariaDB 11.4 as they were no longer needed
MariaDB-tokudb-engine	The TokuDB storage engine. It was disabled in MariaDB 10.5 and removed in MariaDB 10.6

Installing RPM Packages

Preferably, you should install MariaDB RPM packages using the package manager of your Linux distribution, for example `yum` or `zypper`. But you can also use the lower-level `rpm` tool.

Actions Performed by RPM Packages

Users and Groups Created

When the `aria-server` RPM package is installed, it will create a user and group named `mysql`, if it does not already exist.

Installing MariaDB with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux RPM based distributions, these provide MariaDB packages. These are supported by those distributions. If you have a particular need for a later version than what is in the distribution, then MariaDB provides repositories for them.

Using repositories rather than installing RPM allows for an ease of update when a new release is made. It is highly recommended to install the relevant RPM packages from MariaDB's repository using yum or dnf. Centos 7 still uses `yum`, most others use `dnf`, and SUSE/openSUSE use `zypper`.

This page walks you through the simple installation steps using `dnf` and `yum`.

Adding the MariaDB YUM repository

We currently have YUM/DNF repositories for the following Linux distributions, and for the versions that are in standard (not extended) support:

- Red Hat Enterprise Linux (RHEL)
- CentOS
- Fedora
- openSUSE
- SUSE

Using the MariaDB Package Repository Setup Script

MariaDB provides two helpful scripts for setting up repositories, one for MariaDB Community Server named `mariadb_repo_setup`, and one for MariaDB Enterprise Server named `mariadb_es_repo_setup`.

See the Using MariaDB Corporation's Repository Setup Scripts section on the MariaDB Package Repository Setup and Usage page for information on using these scripts.

Using the MariaDB Foundation Repository Configuration Tool

Visit https://mariadb.org/download/?t=repo-config and follow the instructions from there. It will ask for your Linux distribution, desired MariaDB version, and the mirror to use, and will show what files to edit and what commands to run to configure a repository.

Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin your `yum` or `dnf` repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can configure a repository with the URL hard-coded to that specific minor release.

> #### MARIADB CORPORATION REPO SETUP SCRIPTS
>
> If you used MariaDB Corporation's `mariadb_repo_setup` or `mariadb_es_repo_setup` scripts to generate your repository configuration, simply re-run the script and specify the full version number to use with the `--mariadb-server-version` option.
>
> See Pinning the Repository to a Specific Minor Release on the MariaDB Package Repository Setup and Usage page for details.
>
> The full list of MariaDB Enterprise Server releases can be found on the Enterprise Server - All Releases page.
>
> #### MARIADB FOUNDATION REPO CONFIG TOOL
>
> If you used the MariaDB Foundation's Repository Configuration tool, then you need to update the repository file you created to include the full version number to use on the `baseurl` line.

By default the Foundation's tool configures repositories with just the main series of MariaDB, e.g. `mariadb-11.8`, and to pin to a specific version you need to specify the full version, for example `mariadb-11.8.6`.

The full list of MariaDB Community Server releases can be found on the Community Server - All Releases page.

For example, to pin your repository to MariaDB 11.8.6 on RHEL/Alma/Rocky 8, 9, or 10, then you could use the following repository configuration in `/etc/yum.repos.d/MariaDB.repo`:

```
[mariadb]
name = MariaDB-11.8.6
baseurl= http://archive.mariadb.org/mariadb-11.8.6/yum/rhel/$releasever/$basearch
gpgkey= https://archive.mariadb.org/PublicKey
gpgcheck=1
```

After updating the repository configuration, it is a good idea to clean the repository metadata with:

```
sudo dnf clean all
```

Updating the MariaDB YUM repository to a New Major Release

MariaDB's `yum` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `yum` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured `yum` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release that the repository uses by updating the `yum` repository configuration file in-place. For example, if you wanted to change the repository from MariaDB 10.6 to MariaDB 10.11, and if the repository configuration file was at `/etc/yum.repos.d/MariaDB.repo`, then you could execute the following:

```
sudo sed -i 's/10.6/10.11/' /etc/yum.repos.d/MariaDB.repo
```

After that, the repository should refer to MariaDB 10.11.

If the `yum` repository is pinned to a specific minor release, then the above `sed` command can result in an invalid repository configuration. In that case, the recommended options are:

- Edit the `MariaDB.repo` repository file manually.
- Or delete the `MariaDB.repo` repository file, and then install the repository of the new version with the more robust MariaDB Package Repository setup script.

The MariaDB GPG Key

See the GPG page for information on the various keys used by MariaDB.

Installing MariaDB Packages with YUM/DNF

After the `dnf` / `yum` repository is configured, you can install MariaDB by executing the dnf or yum command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages

To Install the most common packages, execute the following command:

```
sudo dnf install MariaDB-server MariaDB-server-galera galera-4 MariaDB-client MariaDB-shared MariaDB-backup MariaDB-common
```

Installing MariaDB Server

To Install MariaDB Server, execute the following command:

```
sudo dnf install MariaDB-server
```

Installing MariaDB Galera Cluster with YUM

> **Note:**
>
> Note for MariaDB 12.3 and later: Galera Cluster support is no longer included in the base `MariaDB-server` package. To enable cluster functionality, you must explicitly install the `MariaDB-server-galera` package. This package contains cluster-specific scripts, systemd bootstrap capability, and the `wsrep_info` plugin.

You need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

To install MariaDB Galera Cluster, you could execute the following command:

```
sudo dnf install MariaDB-server MariaDB-server-galera MariaDB-client galera-4
```

If you haven't yet imported the MariaDB GPG public key, then `yum` will prompt you to import it after it downloads the packages, but before it prompts you to install them.

See MariaDB Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with YUM

MariaDB Connector/C has been included as the client library (statically linked). However, the package name for the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo dnf install MariaDB-client MariaDB-shared
```

If you want compile your own programs against MariaDB Connector/C, execute the following command:

```
sudo dnf install MariaDB-devel
```

Installing mariadb-backup with YUM

To install mariadb-backup, execute the following command:

```
sudo yum install MariaDB-backup
```

Installing Plugins with YUM

Some plugins may also need to be installed.

For example, to install the cracklib_password_check password validation plugin, execute the following command:

```
sudo dnf install MariaDB-cracklib-password-check
```

Installing Debug Info Packages with YUM

The MariaDB `yum` repository also contains debuginfo packages. These package may be needed when debugging a problem.

Installing Debug Info for the Most Common Packages with YUM

To install debuginfo for the most common packages, execute the following command:

```
sudo dnf install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo MariaDB-
backup-debuginfo MariaDB-common-debuginfo
```

All packages have their debuginfo by appending `-debuginfo` to the package name.

Installing Debug Info for MariaDB Server with YUM

To install debuginfo for MariaDB Server, execute the following command:

```
sudo dnf install MariaDB-server-debuginfo
```

Installing Older Versions from the Repository

The MariaDB `yum` repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
sudo dnf list --showduplicates MariaDB-server
```

The output shows the available versions. For example:

```
sudo dnf list --showduplicates MariaDB-server
Last metadata expiration check: 0:01:42 ago on Fri 12 Dec 2025 03:47:20 PM UTC.
Available Packages
MariaDB-server.x86_64  11.8.2-1.el8                              mariadb-main
MariaDB-server.x86_64  12.0.2-1.el8                              mariadb-main
MariaDB-server.x86_64  12.1.2-1.el8                              mariadb-main
mariadb-server.x86_64  3:10.3.39-1.module+el8.8.0+1452+2a7eab68   appstream
```

The MariaDB repository in this example contains MariaDB 12.1.2, 12.0.2, and 11.8.2; and the appstream repository contains MariaDB 10.3.39.

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if dependencies need to be installed, then it will automatically choose to install the latest versions of those packages, which can sometimes break those dependencies. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all.

The MariaDB packages that the `MariaDB-server` package depend on are: `MariaDB-client`, `MariaDB-shared`, and `MariaDB-common`. Therefore, to install MariaDB 12.0.2 from this `yum` repository, we could do the following (putting the version in a variable and each package on its own line so things are cleaner):

```
ver=12.0.2
sudo dnf install \
  MariaDB-server-${ver} \
  MariaDB-client-${ver} \
  MariaDB-shared-${ver} \
  MariaDB-common-${ver}
```

For MariaDB Enterprise it is necessary to specify the release part of the version number as well, but with an underscore (_) instead of a dash (-), as that is how dnf/yum see the version number. For example, for MariaDB Enterprise Server 11.8.5-2 you would specify the version as `11.8.5_2`. For example:

```
ver=11.8.5_2
sudo dnf install \
  MariaDB-server-${ver} \
  MariaDB-client-${ver} \
  MariaDB-shared-${ver} \
  MariaDB-common-${ver}
```

The rest of the install and setup process is as normal.

After Installation

After the installation is complete, you can start MariaDB with:

```
sudo systemctl start mariadb
```

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM packages from MariaDB's repository using zypper.

This page walks you through the simple installation steps using `zypper`.

Adding the MariaDB ZYpp repository

We currently have ZYpp repositories for the following Linux distributions:

- SUSE Linux Enterprise Server (SLES) 12
- SUSE Linux Enterprise Server (SLES) 15
- OpenSUSE 15
- OpenSUSE 42

Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with `zypper`, then you can configure `zypper` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use `zypper` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and mariadb-backup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for MariaDB MaxScale and a repository for MariaDB Tools, which currently only contains Percona XtraBackup and its dependencies.

See MariaDB Package Repository Setup and Usage for more information.

Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with `zypper`, then you can configure `zypper` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use `zypper` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and mariadb-backup. The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.

For example, if you wanted to use the repository to install MariaDB 10.6 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.6/sles/15/x86_64 mariadb
sudo zypper --gpg-auto-import-keys refresh
```

Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the `zypper` repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create a `zypper` repository with the URL hard-coded to that specific minor release.

MARIADB CORPORATION REPO SETUP SCRIPTS

If you used MariaDB Corporation's `mariadb_repo_setup` or `mariadb_es_repo_setup` scripts to generate your repository configuration, simply re-run the script and specify the full version number to use with the `--mariadb-server-version` option.

See Pinning the Repository to a Specific Minor Release on the MariaDB Package Repository Setup and Usage page for details.

The full list of MariaDB Enterprise Server releases can be found on the Enterprise Server - All Releases page.

MARIADB FOUNDATION REPO CONFIG TOOL

If you used the MariaDB Foundation's Repository Configuration tool, then you need to update the repository file you created to include the full version number to use on the `baseurl` line.

By default the Foundation's tool configures repositories with just the main series of MariaDB, e.g. `mariadb-11.8`, and to pin to a specific version you need to specify the full version, for example `mariadb-11.8.6`.

The full list of MariaDB Community Server releases can be found on the Community Server - All Releases page.

For example, to pin your repository to MariaDB 11.8.6 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper removerepo mariadb
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/11.8.6/sles/15/x86_64 mariadb
```

Updating the MariaDB ZYpp repository to a New Major Release

MariaDB's `zypper` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `zypper` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured `zypper` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release that the repository uses by removing the repository for the old version and adding the repository for the new version.

First, you can remove the repository for the old version by executing the following command:

```
sudo zypper removerepo mariadb
```

After that, you can add the repository for the new version. For example, if you wanted to use the repository to install MariaDB 10.6 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.6/sles/15/x86_64 mariadb
sudo zypper --gpg-auto-import-keys refresh
```

After that, the repository should refer to MariaDB 10.6.

Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the `zypper` and `rpm` utilities to verify the integrity of the packages that they install.

See the GPG page for information on the various keys used by MariaDB.

The rpm utility can be used to import this key. For example:

```
sudo rpm --import https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

Once the GPG public key is imported, you are ready to install packages from the repository.

Installing MariaDB Packages with ZYpp

After the `zypper` repository is configured, you can install MariaDB by executing the zypper command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages with ZYpp

To Install the most common packages, execute the following command:

```
sudo zypper install MariaDB-server MariaDB-server-galera galera-4 MariaDB-client MariaDB-shared MariaDB-
backup MariaDB-common
```

Installing MariaDB Server with ZYpp

To Install MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server
```

Installing MariaDB Galera Cluster with ZYpp

> **Note:**
>
> Note for MariaDB 12.3 and later: Galera Cluster support is no longer included in the base `MariaDB-server` package. To enable cluster functionality, you must explicitly install the `MariaDB-server-galera` package. This package contains cluster-specific scripts, systemd bootstrap capability, and the `wsrep_info` plugin.

You also need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

To install MariaDB Galera Cluster, you could execute the following command:

```
sudo zypper install MariaDB-server MariaDB-server-galera MariaDB-client galera-4
```

If you haven't yet imported the MariaDB GPG public key, then `zypper` will prompt you to import it after it downloads the packages, but before it prompts you to install them.

See MariaDB Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with ZYpp

MariaDB Connector/C has been included as the client library. However, the package name for the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client MariaDB-shared
```

Installing mariadb-backup with ZYpp

To install mariadb-backup, execute the following command:

```
sudo zypper install MariaDB-backup
```

Installing Plugins with ZYpp

Some plugins may also need to be installed.

For example, to install the cracklib_password_check password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check
```

Installing Debug Info Packages with ZYpp

The MariaDB `zypper` repository also contains debuginfo packages. These package may be needed when debugging a problem.

Installing Debug Info for the Most Common Packages with ZYpp

To install debuginfo for the most common packages, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo MariaDB-
backup-debuginfo MariaDB-common-debuginfo
```

Installing Debug Info for MariaDB Server with ZYpp

To install debuginfo for MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo
```

Installing Debug Info for MariaDB Clients and Client Libraries with ZYpp

MariaDB Connector/C has been included as the client library. However, the package name for the client library has not been changed.

To install debuginfo for the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client-debuginfo MariaDB-shared-debuginfo
```

Installing Debug Info for mariadb-backup with ZYpp

To install debuginfo for mariadb-backup, execute the following command:

```
sudo zypper install MariaDB-backup-debuginfo
```

Installing Debug Info for Plugins with ZYpp

For some plugins, debuginfo may also need to be installed.

For example, to install debuginfo for the cracklib_password_check password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check-debuginfo
```

Installing Older Versions from the Repository

The MariaDB `zypper` repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
zypper search --details MariaDB-server
```

In the output you will see the available versions.

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if `zypper` has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all.

The core packages required for a server installation include `MariaDB-server`, `MariaDB-client`, `MariaDB-shared`, `MariaDB-backup`, and `MariaDB-common`. For MariaDB 12.3 and later, you must also explicitly include the `MariaDB-server-galera` package if cluster functionality is required.

Therefore, to install MariaDB 10.6.21 from this `zypper` repository, we would do the following:

```
sudo zypper install MariaDB-server-10.6.21 MariaDB-client-10.6.21 MariaDB-shared-10.6.21 MariaDB-backup-10.6.21 MariaDB-common-10.6.21
```

To install MariaDB 12.3 (including Galera support):"

```
sudo zypper install MariaDB-server-12.3.2 MariaDB-server-galera-12.3.2 MariaDB-client-12.3.2 MariaDB-shared-12.3.2 MariaDB-backup-12.3.2 MariaDB-common-12.3.2
```

The rest of the install and setup process is as normal.

After Installation

After the installation is complete, you can start MariaDB.

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

This page is licensed: CC BY-SA / Gnu FDL

Checking MariaDB RPM Package Signatures

MariaDB RPM packages since MariaDB 5.1.55 are signed.

For **MariaDB Community Server**, see the MariaDB Community Server RPM / Source Keys section of the GPG page for details on how to import the key used by those repositories.

For **MariaDB Enterprise Server**, see the MariaDB Enterprise GPG Keys section of the GPG page for details on how to import the key used by those repositories.

To check the signature you first need to import the public part of the key like so:

```
gpg --keyserver hkp://pgp.mit.edu --recv-keys 1BB943DB
```

Next you need to let pgp know about the key like so:

```
gpg --export --armour 1BB943DB > mariadb-signing-key.asc
sudo rpm --import mariadb-signing-key.asc
```

You can check to see if the key was imported with:

```
rpm -qa gpg-pubkey*
```

Once the key is imported, you can check the signature of the MariaDB RPM files by running the something like the following in your download directory:

```
rpm --checksig $(find . -name '*.rpm')
```

The output of the above will look something like this (make sure gpg shows up on each OK line):

```
me@desktop:~$ rpm --checksig $(find . -name '*.rpm')
./kvm-rpm-centos5-amd64/rpms/MariaDB-test-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-server-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-client-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-shared-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-devel-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-debuginfo-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/srpms/MariaDB-5.1.55-98.el5.src.rpm: (sha1) dsa sha1 md5 gpg OK
```

Installing MariaDB With the rpm Tool

This article describes how to download the RPM files and install them using the `rpm` command.

It is highly recommended to Install MariaDB with yum where possible.

Navigate toand choose the desired database version and then select the RPMs that match your Linux distribution and architecture.

Clicking those links takes you to a local mirror. Choose the rpms link and download the desired packages. The packages will be similar to the following:

```
MariaDB-client-5.2.5-99.el5.x86_64.rpm
MariaDB-debuginfo-5.2.5-99.el5.x86_64.rpm
MariaDB-devel-5.2.5-99.el5.x86_64.rpm
MariaDB-server-5.2.5-99.el5.x86_64.rpm
MariaDB-shared-5.2.5-99.el5.x86_64.rpm
MariaDB-test-5.2.5-99.el5.x86_64.rpm
```

For a standard server installation you will need to download at least the *client*, *shared*, and *server* RPM files. See About the MariaDB RPM Files for more information about what is included in each RPM package.

After downloading the MariaDB RPM files, you might want to check their signatures. See Checking MariaDB RPM Package Signatures for more information about checking signatures.

```
rpm --checksig $(find . -name '*.rpm')
```

Prior to installing MariaDB, be aware that it will conflict with an existing installation of MySQL. To check whether MySQL is already installed, issue the command:

```
rpm -qa 'mysql*'
```

If necessary, you can remove found MySQL packages before installing MariaDB.

To install MariaDB, use the command:

```
rpm -ivh MariaDB-*
```

You should see output such as the following:

```
Preparing...                ########################################### [100%]
   1:MariaDB-shared         ########################################### [ 14%]
   2:MariaDB-client         ########################################### [ 29%]
   3:MariaDB-client         ########################################### [ 43%]
   4:MariaDB-debuginfo      ########################################### [ 57%]
   5:MariaDB-devel          ########################################### [ 71%]
   6:MariaDB-server         ########################################### [ 86%]

PLEASE REMEMBER TO SET A PASSWORD FOR THE MariaDB root USER !
To do so, start the server, then issue the following commands:

/usr/bin/mariadb-admin -u root password 'new-password'
/usr/bin/mariadb-admin -u root -h hostname password 'new-password'

Alternatively you can run:
/usr/bin/mysql_secure_installation

which will also give you the option of removing the test
databases and anonymous user created by default.  This is
strongly recommended for production servers.

See the MySQL manual for more instructions.

Please report any problems with the /usr/bin/mysqlbug script!

The latest information about MariaDB is available at http://www.askmonty.org/.
You can find additional information about the MySQL part at:
http://dev.mysql.com
Support MariaDB development by buying support/new features from
Monty Program Ab. You can contact us about this at sales@askmonty.org.
Alternatively consider joining our community based development effort:
http://askmonty.org/wiki/index.php/MariaDB#How_can_I_participate_in_the_development_of_MariaDB

Starting MySQL....[  OK  ]
Giving mysqld 2 seconds to start
   7:MariaDB-test           ########################################### [100%]
```

Be sure to follow the instructions given in the preceding output and create a password for the root user either by using mariadb-admin or by running the `/usr/bin/mysql_secure_installation` script.

Installing the MariaDB RPM files installs the MySQL tools in the `/usr/bin` directory. You can confirm that MariaDB has been installed by using the mariadb client program. Issuing the command `mariadb` should give you the MariaDB cursor.

MariaDB for DirectAdmin Using RPMs

If you are using DirectAdmin and you encounter any issues with Installing MariaDB with YUM, then the directions below may help. The process is very straightforward.

> **Note:**
>
> Installing with YUM is preferable to installing the MariaDB RPM packages manually, so only do this if you are having issues such as:
> Starting httpd:
>
> ```
> httpd:
>   Syntax error on line 18 of /etc/httpd/conf/httpd.conf:
>   Syntax error on line 1 of /etc/httpd/conf/extra/httpd-phpmodules.conf:
>     Cannot load /usr/lib/apache/libphp5.so into server:
>       libmysqlclient.so.18: cannot open shared object file: No such file or directory
> ```

Or:

```
Starting httpd:
  httpd:
    Syntax error on line 18 of /etc/httpd/conf/httpd.conf:
    Syntax error on line 1 of /etc/httpd/conf/extra/httpd-phpmodules.conf:
      Cannot load /usr/lib/apache/libphp5.so into server:
        /usr/lib/apache/libphp5.so: undefined symbol: client_errors
```

RPM Installation

To install the RPMs, there is a quick and easy guide to Installing MariaDB with the RPM Tool. Follow the instructions there.

Necessary Edits

We do not want DirectAdmin's custombuild to remove/overwrite our MariaDB installation whenever an update is performed. To rectify this, disable automatic MySQL installation.

Edit `/usr/local/directadmin/custombuild/options.conf` and replace `mysql_inst=yes` with `mysql_inst=no`

```
sudo sed -i 's/^mysql_inst=yes/mysql_inst=no/' /usr/local/directadmin/custombuild/options.conf
```

> **Warning:**
>
> When MariaDB is installed manually (i.e. not using YUM), updates are not automatic. You will need to update the RPMs yourself.

This page is licensed: CC BY-SA / Gnu FDL

MariaDB Installation via RPMs on CentOS 7

This guide provides the detailed steps for installing MariaDB 10.1.21 via individual RPM packages on CentOS 7. The process involves installing dependencies, then the main packages, and resolving potential conflicts as they appear.

The RPMs needed for the installation are available from the MariaDB website. The required packages for this guide are:

```
jemalloc-3.6.0-1.el7.x86_64.rpm
MariaDB-10.1.21-centos7-x86_64-client.rpm
MariaDB-10.1.21-centos7-x86_64-compat.rpm
galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm
jemalloc-devel-3.6.0-1.el7.x86_64.rpm
MariaDB-10.1.21-centos7-x86_64-common.rpm
MariaDB-10.1.21-centos7-x86_64-server.rpm
```

Step-by-Step Installation

1. Install Basic Dependencies

First, use yum to install some general system packages that may be required.

```
yum install rsync nmap lsof perl-DBI nmap-ncat
```

2. Install MariaDB RPM Packages

Next, install the downloaded RPMs in sequence. Make sure to run these commands as a user with sufficient privileges (e.g., using sudo).

```
rpm -ivh jemalloc-3.6.0-1.el7.x86_64.rpm
rpm -ivh jemalloc-devel-3.6.0-1.el7.x86_64.rpm
rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm
rpm -ivh MariaDB-10.1.21-centos7-x86_64-compat.rpm
rpm -ivh MariaDB-10.1.21-centos7-x86_64-client.rpm
rpm -ivh galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm
rpm -ivh MariaDB-10.1.21-centos7-x86_64-server.rpm
```

> **Warning:**
>
> During this process, you may encounter errors related to dependencies or conflicts. The sections below describe these common issues and their solutions.

Troubleshooting Common Installation Errors and Warnings

Error 1: Package Conflict with `mariadb-libs`

> **ERROR MESSAGE**
>
> While installing `mariadb-common`, you may encounter a conflict with an existing package.
>
> ```
> # rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm
>
> warning: MariaDB-10.1.21-centos7-x86_64-common.rpm: Header V4 DSA/SHA1 Signature, key ID 1bb943db: NOKEY
> error: Failed dependencies:
>     mariadb-libs < 1:10.1.21-1.el7.centos conflicts with MariaDB-common-10.1.21-1.el7.centos.x86_64
> ```
>
> **SOLUTION**
>
> You must find and remove the conflicting `mariadb-libs` package.

```
# Search for the installed package
rpm -qa | grep mariadb-libs
# Expected output: mariadb-libs-5.5.52-1.el7.x86_64

# Remove the conflicting package (use the exact name from the command above)
rpm -ev --nodeps mariadb-libs-5.5.52-1.el7.x86_64
```

After removing it, you can run the `rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm` command again.

Error 2: Failed Dependency for Galera

ERROR MESSAGE

While installing the Galera package, the installation may fail due to a missing library.

```
# rpm -ivh galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm

error: Failed dependencies:
    libboost_program_options.so.1.53.0()(64bit) is needed by galera-25.3.19-1.rhel7.el7.centos.x86_64
```

SOLUTION

The required dependency `libboost_program_options` can be installed using yum.

```
yum install boost-devel.x86_64
```

After installing `boost-devel`, you can run the `rpm -ivh galera...` command again.

Warning: GPG Key `NOKEY`

WARNING MESSAGE

You may also see a warning about a missing GPG key during the installation.

```
warning: galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm: Header V4 DSA/SHA1 Signature, key ID 1bb943db:
NOKEY
```

SOLUTION

This warning can be resolved by importing the official MariaDB GPG key.

```
rpm --import http://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

Post-Installation

After all RPMs are successfully installed, the final step is to secure the server. This involves setting the root password, removing test databases, and disallowing remote root login.

```
# First, start the newly installed MariaDB service
systemctl start mariadb

# Now, run the security script and follow the prompts
mysql_secure_installation
```

Troubleshooting MariaDB Installs on RHEL / CentOS

The following article is about different issues people have encountered when installing MariaDB on RHEL / CentOS.

It is highly recommended to install with yum where possible.

In RHEL/ CentOS it is also possible to install a RPM or a tar ball. The RPM is the preferred version, except if you want to install many versions of MariaDB or install MariaDB in a non standard location.

Replacing MySQL

If you removed an MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames `/etc/my.cnf` to `/etc/my.cnf.rpmsave.`

After installing MariaDB you should do the following to restore your configuration options:

```
mv /etc/my.cnf.rpmsave /etc/my.cnf
```

Unsupported configuration options

If you are using any of the following options in your `/etc/my.cnf` or other `my.cnf` file you should remove them. This is also true for MySQL 5.1 or newer:

```
skip-bdb
```

Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms

MariaDB source RPMs (SRPMs) are not packaged on all platforms for which MariaDB RPMs are packaged.

The reason is that MariaDB's build process relies heavily on cmake for a lot of things. In this specific case, MariaDB's build process relies on CMake CPack Package Generators to build RPMs. The specific package generator that it uses to build RPMs is called CPackRPM.

Support for source RPMs in CPackRPM became usable with MariaDB's build system starting from around cmake 3.10. This means that we do not produce source RPMs on platforms where the installed cmake version is older than that.

See also Building MariaDB from a Source RPM.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB Alongside MySQL

MariaDB was originally designed as a drop-in replacement of MySQL, with more features, new storage engines, fewer bugs, and better performance, but you can also install it alongside MySQL. (This can be useful, for example, if you want to migrate databases/applications one by one.)

Here are the steps to install MariaDB near an existing MySQL installation.

- Download the compiled binary tar.gz file that contains the latest version.
- Extract the files in a directory of your choice. In the following, we assume you chose the `/opt` directory.

```
[root@mariadb-near-mysql ~]# cat /etc/issue
CentOS release 6.2 (Final)

[root@mariadb-near-mysql ~]# rpm -qa mysql*
mysql-5.1.61-1.el6_2.1.x86_64
mysql-libs-5.1.61-1.el6_2.1.x86_64
mysql-server-5.1.61-1.el6_2.1.x86_64

[root@mariadb-near-mysql ~]# ps axf | grep mysqld
 2072 pts/0    S+     0:00          \_ grep mysqld
 1867 ?        S      0:01 /bin/sh /usr/bin/mysqld_safe --datadir=/var/lib/mysql --
socket=/var/lib/mysql/mysql.sock ...
 1974 ?        Sl     0:06  \_ /usr/libexec/mysqld --basedir=/usr --datadir=/var/lib/mysql --user=mysql
...
```

- Create data directory and symlinks as below:

```
[root@mariadb-near-mysql opt]# mkdir mariadb-data
[root@mariadb-near-mysql opt]# ln -s mariadb-5.5.24-linux-x86_64 mariadb
[root@mariadb-near-mysql opt]# ls -al
total 20
drwxr-xr-x.  5 root root 4096 2012-06-06 07:27 .
dr-xr-xr-x. 23 root root 4096 2012-06-06 06:38 ..
lrwxrwxrwx.  1 root root   27 2012-06-06 07:27 mariadb -> mariadb-5.5.24-linux-x86_64
drwxr-xr-x. 13 root root 4096 2012-06-06 07:07 mariadb-5.5.24-linux-x86_64
drwxr-xr-x.  2 root root 4096 2012-06-06 07:26 mariadb-data
```

- Create group mariadb and user mariadb and set correct ownerships:

```
[root@mariadb-near-mysql opt]# groupadd --system mariadb
[root@mariadb-near-mysql opt]# useradd -c "MariaDB Server" -d /opt/mariadb -g mariadb --system mariadb
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-5.5.24-linux-x86_64/
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-data/
```

- Create a new my.cnf in /opt/mariadb from support files:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/my-medium.cnf mariadb-data/my.cnf
[root@mariadb-near-mysql opt]# chown mariadb:mariadb mariadb-data/my.cnf
```

- Edit the file /opt/mariadb-data/my.cnf and add custom paths, socket, port, user and the most important of all: data directory and base directory. Finally the file should have at least the following:

```
[client]
port        = 3307
socket      = /opt/mariadb-data/mariadb.sock

[mysqld]
datadir         = /opt/mariadb-data
basedir         = /opt/mariadb
port        = 3307
socket      = /opt/mariadb-data/mariadb.sock
user            = mariadb
```

- Copy the init.d script from support files in the right location:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/mysql.server /etc/init.d/mariadb
[root@mariadb-near-mysql opt]# chmod +x /etc/init.d/mariadb
```

- Edit /etc/init.d/mariadb replacing mysql with mariadb as below:

```
- # Provides: mysql
+ # Provides: mariadb
- basedir=
+ basedir=/opt/mariadb
- datadir=
+ datadir=/opt/mariadb-data
- lock_file_path="$lockdir/mysql"
+ lock_file_path="$lockdir/mariadb"
```

The trickiest part will be the last changes to this file. You need to tell mariadb to use only one configuration file. In the **start** section after**$bindir/mysqld_safe** add **–defaults-file=/opt/mariadb-data/my.cnf**. Finally the lines should look like:

```
# Give extra arguments to mysqld with the my.cnf file. This script
# may be overwritten at next upgrade.
$bindir/mysqld_safe --defaults-file=/opt/mariadb-data/my.cnf --datadir="$datadir" --pid-
file="$mysqld_pid_file_path" $other_args >/dev/null 2>&1 &
```

The same change needs to be made to the mariadb-admin command below in the wait_for_ready() function so that the mariadb start command can properly listen for the server start. In the **wait_for_ready()** function, after **$bindir/mariadb-admin** add **–defaults-file=/opt/mariadb-data/my.cnf**. The lines should look like:

```
wait_for_ready () {
[...]
    if $bindir/mariadb-admin --defaults-file=/opt/mariadb-data/my.cnf ping >/dev/null 2>&1; then
```

- Run mariadb-install-db by explicitly giving it the my.cnf file as argument:

```
[root@mariadb-near-mysql opt]# cd mariadb
[root@mariadb-near-mysql mariadb]# scripts/mariadb-install-db --defaults-file=/opt/mariadb-data/my.cnf
```

- Now you can start MariaDB by

```
[root@mariadb-near-mysql opt]# /etc/init.d/mariadb start
Starting MySQL...                                          [  OK  ]
```

- Make MariaDB start at system start:

```
[root@mariadb-near-mysql opt]# cd /etc/init.d
[root@mariadb-near-mysql init.d]# chkconfig --add mariadb
[root@mariadb-near-mysql init.d]# chkconfig --levels 3 mariadb on
```

- Finally test that you have both instances running:

```
[root@mariadb-near-mysql ~]# mysql -e "SELECT VERSION();"
+-----------+
| VERSION() |
+-----------+
| 5.1.61    |
+-----------+
[root@mariadb-near-mysql ~]# mysql -e "SELECT VERSION();" --socket=/opt/mariadb-data/mariadb.sock
+----------------+
| VERSION()      |
+----------------+
| 5.5.24-MariaDB |
+----------------+
```

What about MariaDB Upgrades ?

By having the **mariadb.socket**, **my.cnf** file and **databases** in **/opt/mariadb-data** means that if you want to upgrade the MariaDB version you will only need to:

- Extract the new version from the archive in `/opt` near the current version,
- Stop MariaDB.
- Change the symlink mariadb to point to the new directory.
- Start MariaDB.
- Run upgrade script… but remember you will need to provide the socket option – `socket=/opt/mariadb-data/mariadb.sock` .

Installing MariaDB Binary Tarballs

> **Note:**
>
> Starting with MariaDB 12.3, the generic binary tarballs (bintars) no longer include the Galera Cluster library or management scripts by default. Users requiring cluster functionality should obtain these libraries from the official MariaDB repositories or via the `mariadb-server-galera` package.

Binary tarballs (bintars) are compressed tar archives that contain pre-compiled executables, libraries, and other deployment dependencies. They can usually be installed on any modern Linux distribution.

MariaDB Binary tarballs are named following the pattern: `mariadb-VERSION-OS.tar.gz` . Be sure to download the correct version for your machine.

> **Warning:**
>
> Some older binary tarballs are marked *'(GLIBC_2.14)'* or *'(requires GLIBC_2.14+)'*. These binaries are built the same as the others, but on a newer build host, and they require GLIBC 2.14 or higher. Use the other binaries for machines with older versions of GLIBC installed. Run `ldd --version` to see which version is running on your distribution.
> Others are marked `systemd` , which are for systems with `systemd` and GLIBC 2.19 or higher.

Benefits of Binary Tarballs

Binary tarballs provide multiple benefits:

- They are highly OS independent. As long as you get the `bintar` for the architecture, GLIBC version, and if you are using `systemd` or not, the `bintar` should work almost anywhere.
- You do not need to be root to use them.
  - They can be installed by anyone to any path, including one's home directory.
- You can have any number of different MariaDB installations on the same machine. This is often desired during upgrades when one wants to have the old installation running until switching to the new one.
- You can use them on systems for which MariaDB does not support native packages.

Installing binary tarballs

To install the binaries, unpack the distribution into the directory of your choice and run the mariadb-install-db script.

In the example below, we install MariaDB in the `/usr/local/mysql` directory (this is the default location for MariaDB for many platforms). However, any other directory should work too.

We install the binary with a symlink to the original name. This is done so that you can easily change MariaDB versions just by moving the symlink to point to another directory.

Ensure You Use the Correct my.cnf Files

MariaDB searches for the configuration files '`/etc/my.cnf`' (on some systems '`/etc/mysql/my.cnf`') and '`~/.my.cnf`'. If you have an old `my.cnf` file (maybe from a system installation of MariaDB or MySQL), you need to take care that you don't accidentally use the old one with your new binary .tar installation.

The normal solution for this is to ignore the `my.cnf` file in `/etc` when you use the programs in the tar file.

This is done by creating your own .my.cnf file in your home directory and telling mariadb-install-db,mysqld_safe, and possibly mariadb (the command-line client utility) to **only** use this one with the option '`--defaults-file=~/.my.cnf`'. Note that this has to be the first option for the above commands!

Installing MariaDB as root in /usr/local/mysql

If you have root access to the system, you probably want to install MariaDB under the user and group 'mysql' (to keep compatibility with MySQL installations):

```
groupadd mysql
useradd -g mysql mysql
cd /usr/local
tar -zxvpf /path-to/mariadb-VERSION-OS.tar.gz
ln -s mariadb-VERSION-OS mysql
cd mysql
./scripts/mariadb-install-db --user=mysql
chown -R root .
chown -R mysql data
```

The symlinking with `ln -s` is recommended as it makes it easy to install many MariaDB versions at the same time (for easy testing, upgrading, downgrading, etc).

If you are installing MariaDB to replace MySQL, then you can leave out the call to `mariadb-install-db`. Instead, shut down MySQL. MariaDB should find the path to the data directory from your old `/etc/my.cnf` file (path may vary depending on your system).

To start mariadbd, you should now do:

```
./bin/mariadbd-safe --user=mysql &
or
./bin/mariadbd-safe --defaults-file=~/.my.cnf --user=mysql &
```

To test the connection, modify your $PATH so you can invoke clients such as mariadb, mariadb-dump, etc.

```
export PATH=$PATH:/usr/local/mysql/bin/
```

You may want to modify your .bashrc or .bash_profile to make it permanent.

Installing MariaDB as Not root in Any Directory

Below, change /usr/local to the directory of your choice.

```
cd /usr/local
gunzip < /path-to/mariadb-VERSION-OS.tar.gz | tar xf -
ln -s mariadb-VERSION-OS mysql
cd mysql
./scripts/mariadb-install-db --defaults-file=~/.my.cnf
```

If you have problems with the above gunzip command line, you can instead, if you have gnu tar, do:

```
tar xfz /path-to/mariadb-VERSION-OS.tar.gz
```

To start mariadbd, you should now do:

```
./bin/mariadbd-safe --defaults-file=~/.my.cnf &
```

Auto Start of mariadbd

You can get mariadbd (the MariaDB server) to autostart by copying the file `mysql.server` file to the right place.

```
cp support-files/mysql.server /etc/init.d/mysql.server
```

The exact place depends on your system. The `mysql.server` file contains instructions on how to use and fine tune it.

For systemd installation, the mariadb.service file will need to be copied from the `support-files/systemd` folder to the `/usr/lib/systemd/system/` folder.

```
cp support-files/systemd/mariadb.service /usr/lib/systemd/system/mariadb.service
```

After this, you can start the service using this command:

```
systemctl start mariadb.service
```

Stop the service with this command:

```
systemctl stop mariadb.service
```

Please refer to the systemd page for further information.

Post Installation

After this, remember to set proper passwords for all accounts accessible from untrusted sources, to avoid exposing the host to security risks!

Also consider using the mysql.server to start MariaDB automatically when your system boots.

On systems using systemd, instead, enable automatic startup during system boot with this command:

```
systemctl enable mariadb.service
```

For details on the exact steps used to build the binaries, see the compiling MariaDB section.

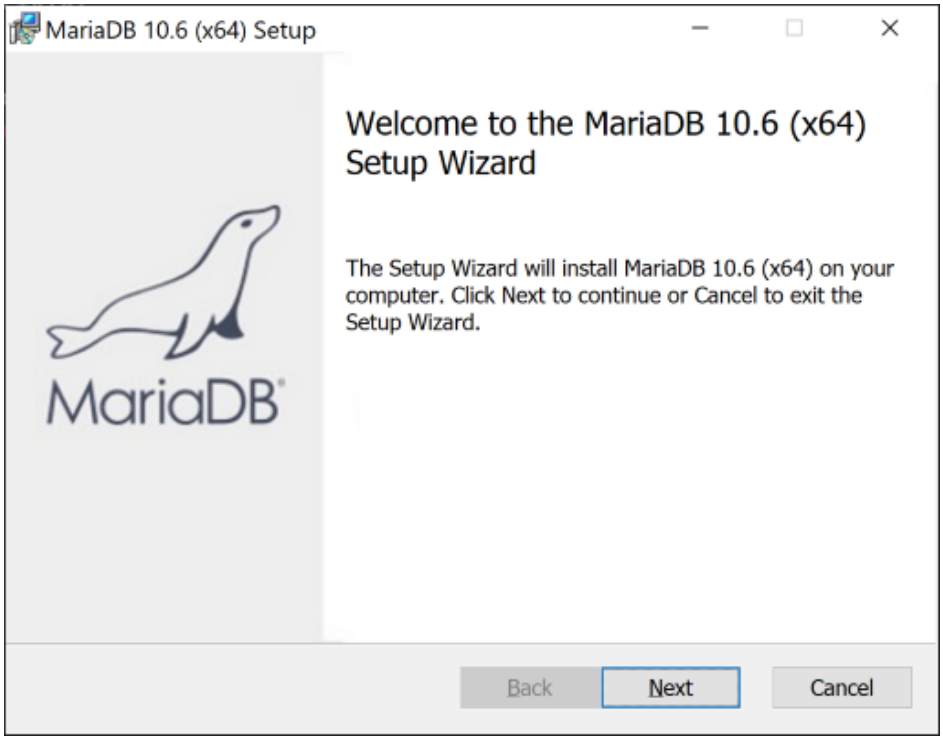
Installing MariaDB MSI Packages on Windows

MSI packages is available for x64 (64 bit) processor architectures and, in some older releases only, for x86 (32 bit). We use screenshots from an x64 installation in the following.

Installation UI

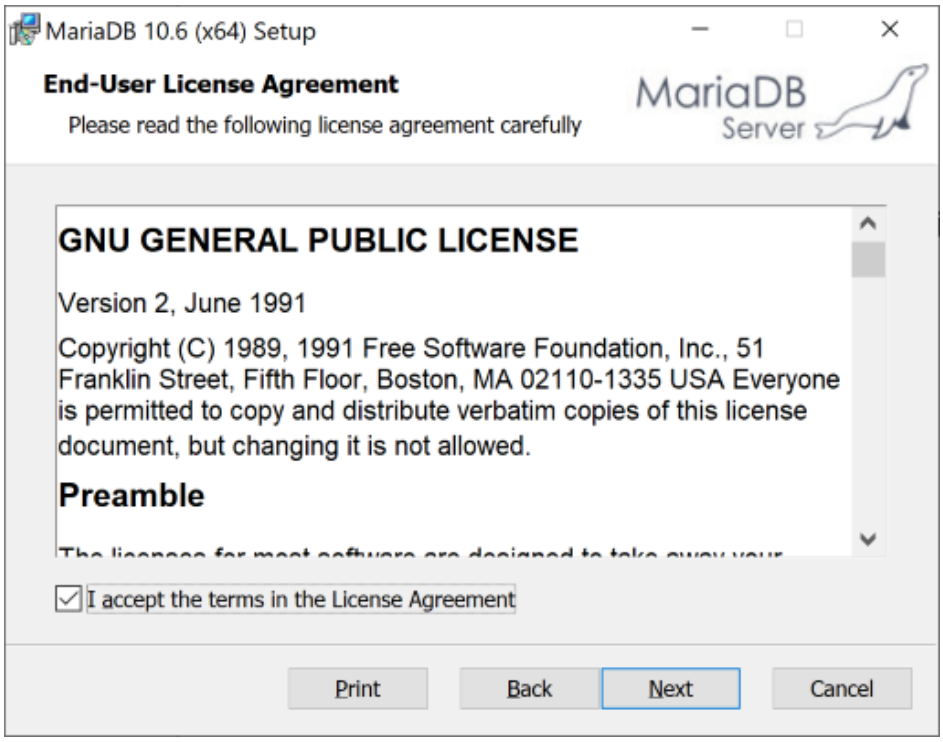
This is the typical mode of installation. To start the installer, click on the mariadb-…msi.

Welcome



Welcome dialog

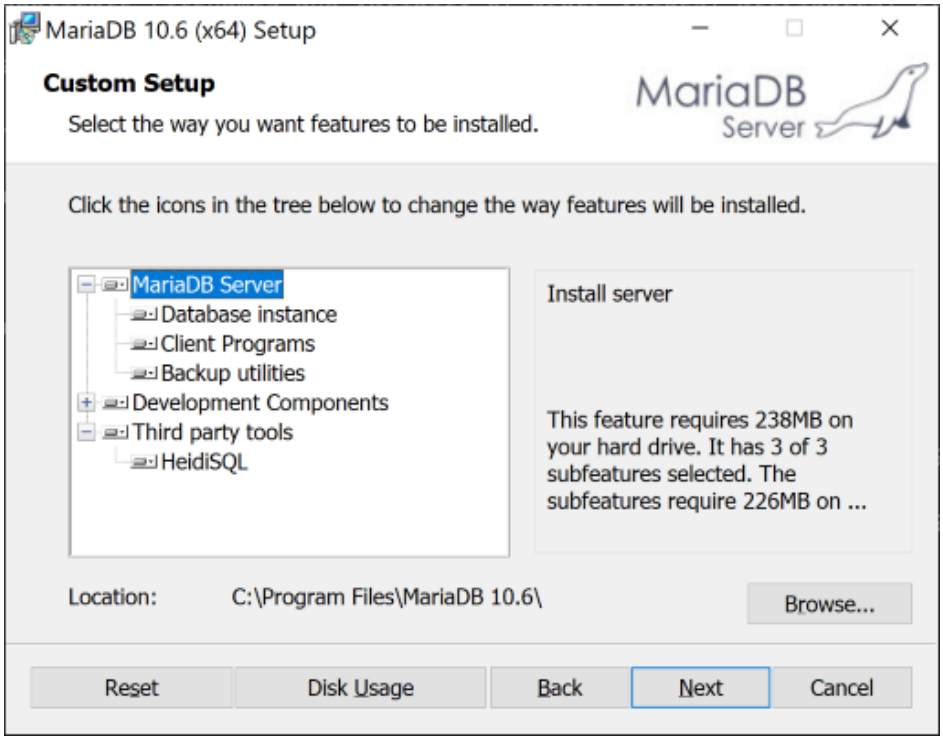
License Agreement



License Agreement

You must accept the terms in the license agreement. Proceed to the next dialog.

Custom Setup

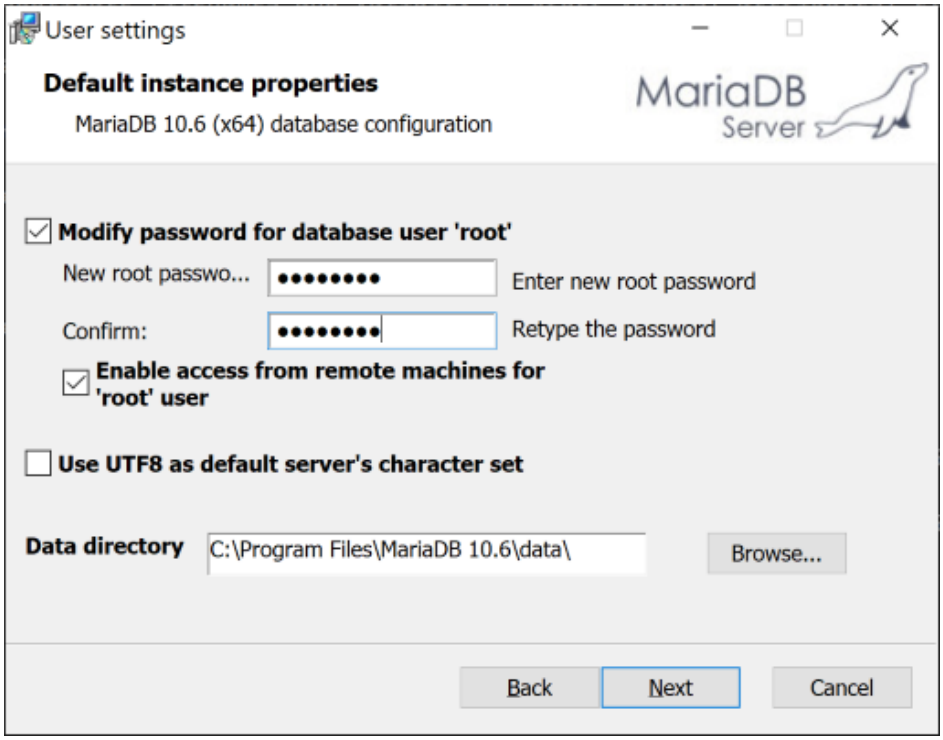


Custom Setup

Choose what features to install. By default, all features are installed with the exception of the debug symbols. If the "Database instance" feature is selected, the installer will create a database instance, by default running as a service. In this case the installer will present additional dialogs to control various database properties. Note that you do not necessarily have to create an instance at this stage. For example, if you already have MySQL or MariaDB databases running as services, you can just upgrade them during the installation. Also, you can create additional database instances after the installation, with the mysql_install_db.exe utility.

> **Note:**
>
> By default, if you install a database instance, the data directory are in the `data` folder under the installation root. To change the data directory location, select `Database instance` in the feature tree, and use the `Browse` button to select another location.

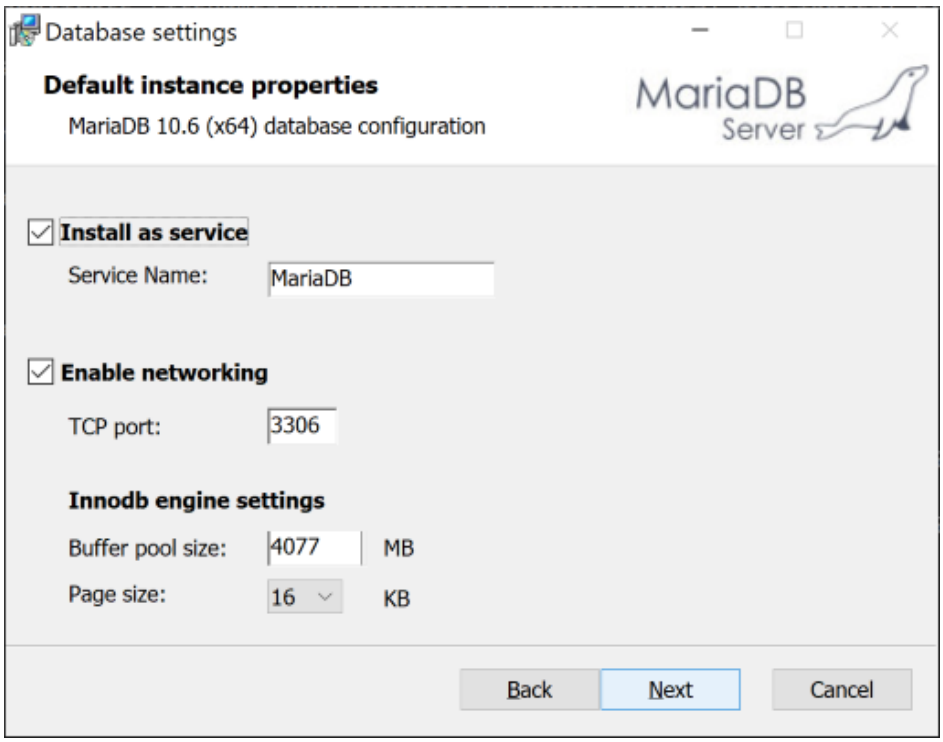
Database Authentication/Security Related Properties



Database security properties

This dialog is shown if you selected the *Database instance* feature. Here, you can set the password for the “root” database user and specify whether root can access databases from remote machines. The *Create anonymous account* setting allows for anonymous (non-authenticated) users. It is off by default; it is not recommended to change this setting.

Other Database Properties

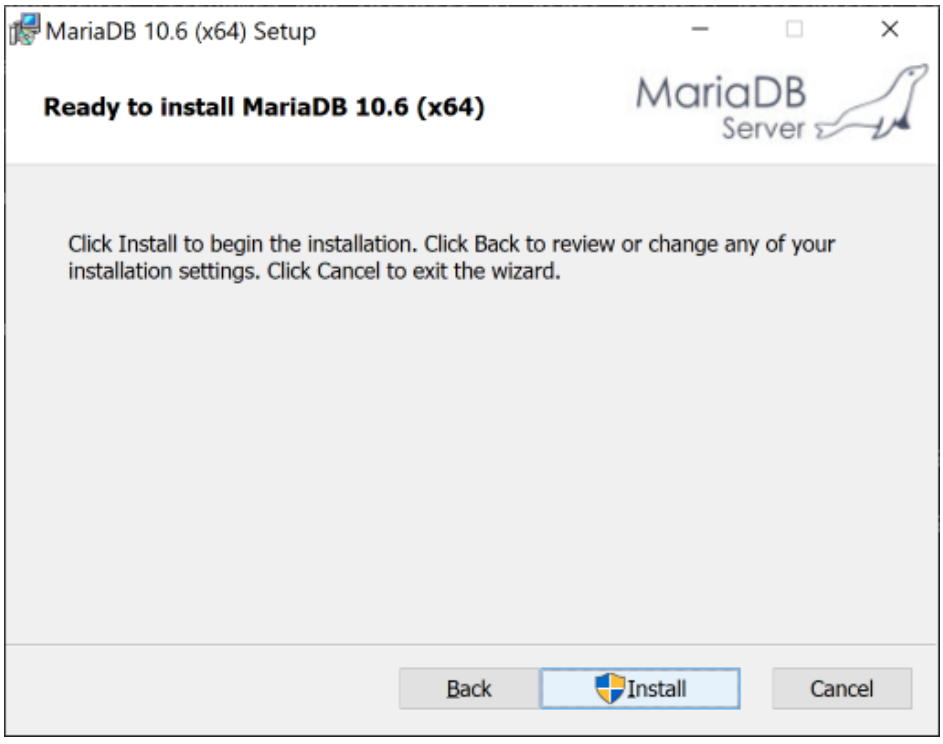


Other database properties

- Install as service.

- Defines whether the database should be run as a service. If it should be run as a service, then it also defines the service name. It is recommended to run your database instance as a service as it greatly simplifies database management. In MariaDB 10.4 and later, the default service name used by the MSI installer is “MariaDB”. In 10.3 and before, the default service name used by the MSI installer is “MySQL”. Note that the default service name for the –install and –install-manual options for `mysqld.exe` is “MySQL” in all versions of MariaDB.
- Enable Networking.
- Whether to enable TCP/IP (recommended) and which port MariaDB should listen to. If security is a concern, you can change the bind-address parameter post-installation to bind to only local addresses. If the “Enable networking” checkbox is deselected, the database will use named pipes for communication.
- InnoDB engine settings.
- Defines the InnoDB buffer pool size, and the InnoDB page size. The default buffer pool size is 12.5% of RAM, and depending on your requirements you can give InnoDB more (up to 70-80% RAM). 32 bit versions of MariaDB have restrictions on maximum buffer pool size, which is approximately 1GB, due to virtual address space limitations for 32bit processes. A 16k page size is suitable for most situations. See the innodb_page_size system variable for details on other settings.

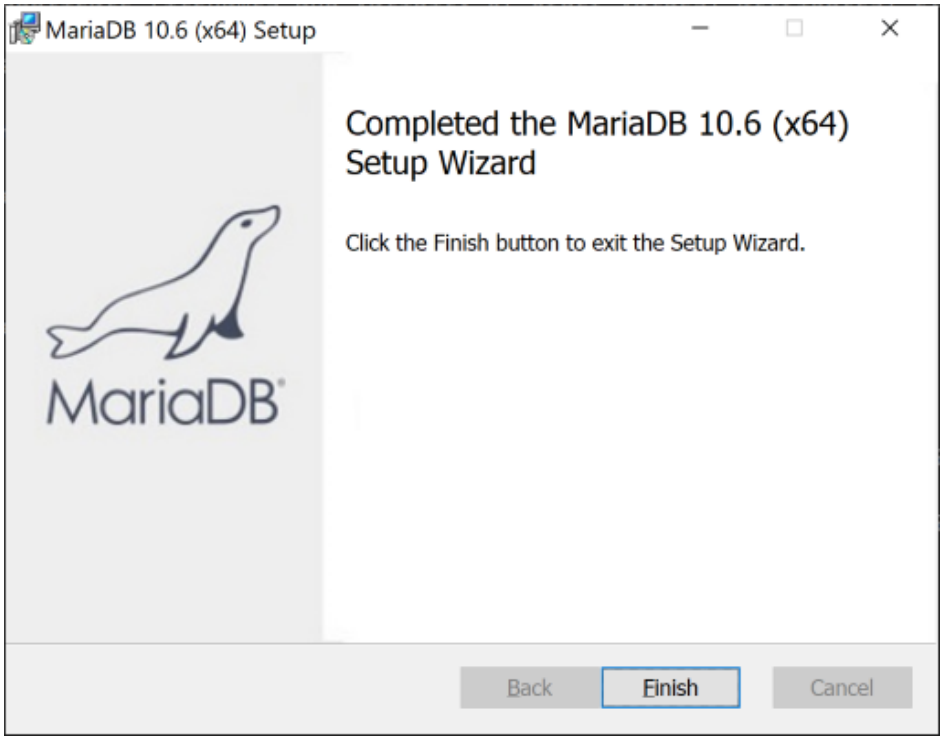
Ready to Install



Ready Dialog

At this point, all installation settings are collected. Click on the “Install” button.

End



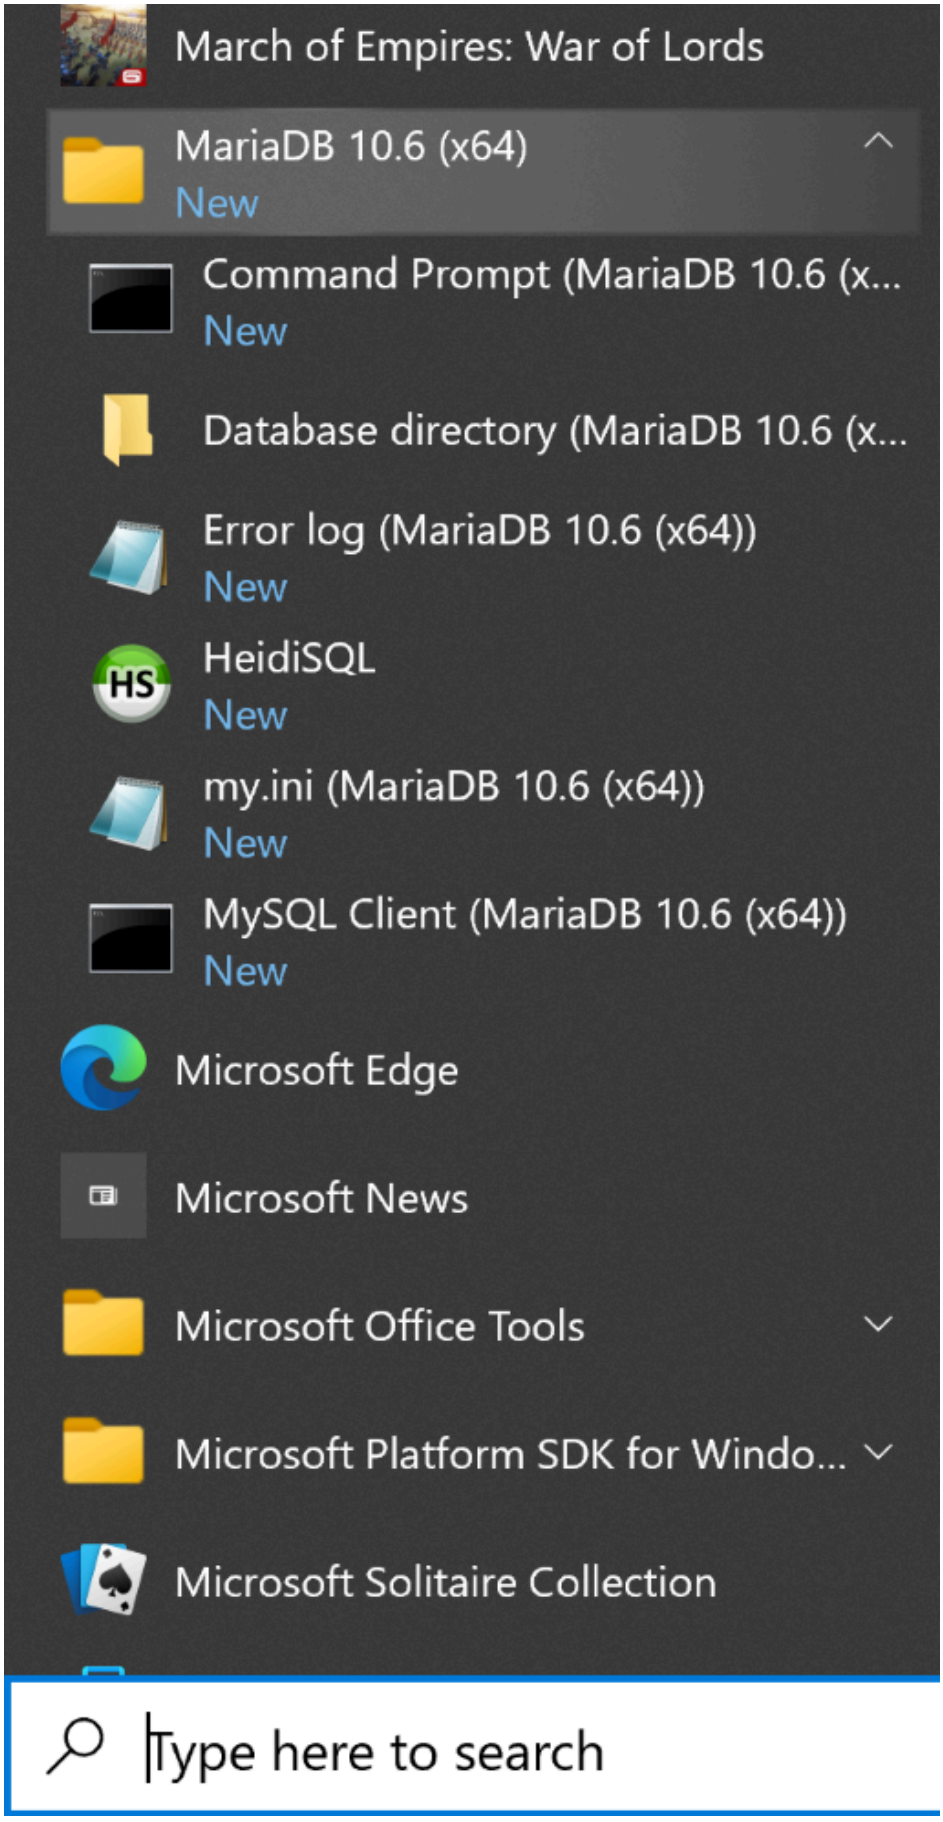
Finish

Installation is finished now. If you have upgradable instances of MariaDB/MySQL, running as services, this dialog will present a “Do you want to upgrade existing instances” checkbox (if selected, it launches the Upgrade Wizard post-installation).

If you installed a database instance as service, the service will be running already.

New Entries in Start Menu

Installation will add some entries in the Start Menu:



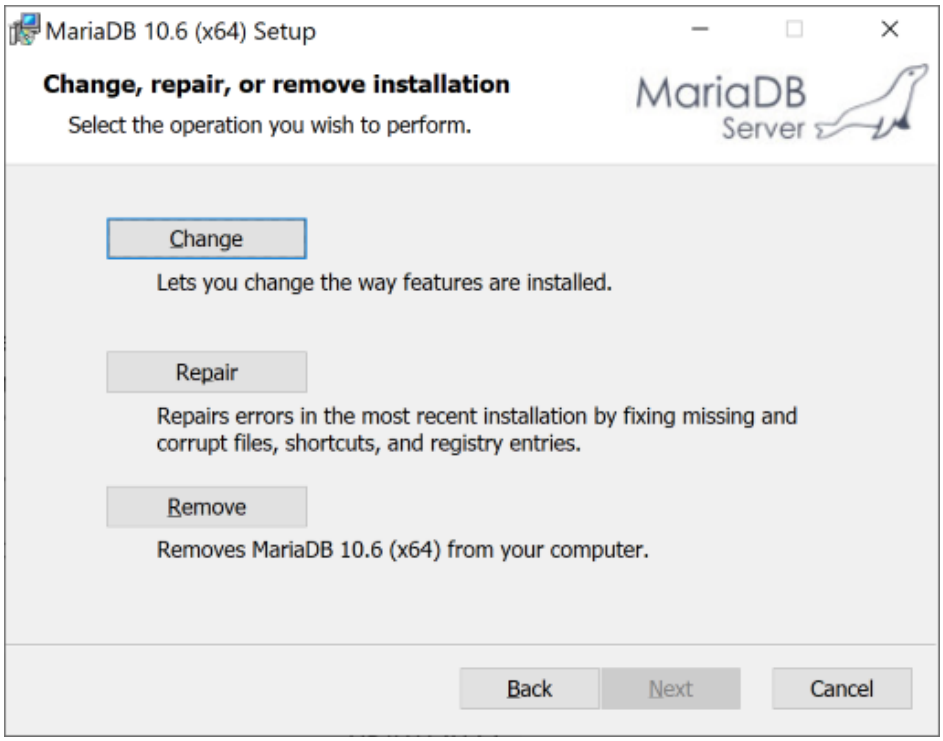
Start Menu

- **MariaDB Client** - Starts command line client mysql.exe.

- **Command Prompt** - Starts a command prompt. Environment is set such that “bin” directory of the installation is included into PATH environment variable, for instance, use this command prompt to issue MariaDB commands (for example, mysqldadmin or mysql).
- **Database directory** - Opens the data directory in Explorer.
- **Error log** - Opens the database error log in Notepad.
- **my.ini** - Opens the database configuration file my.ini in Notepad.
- **Upgrade Wizard** - Starts the Wizard to upgrade an existing MariaDB/MySQL database instance to this MariaDB version.

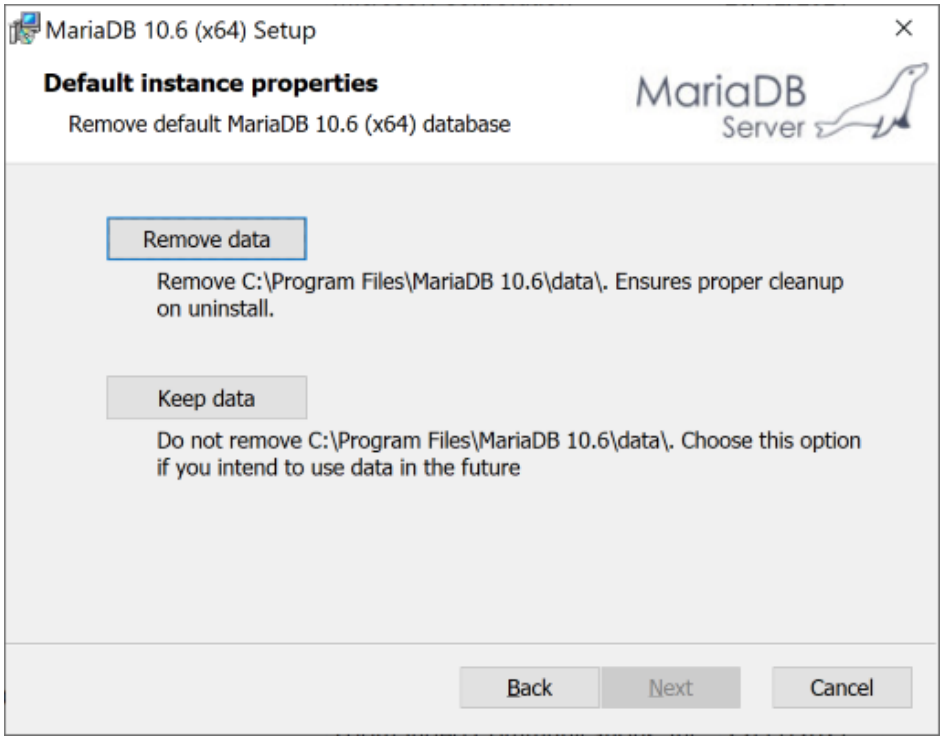
Uninstall UI

In the Explorer applet *Programs and Features*, find the entry for MariaDB, choose *Uninstall/Change* and click on the `Remove` button in the dialog:



UninstallChangeDialog_New

If you installed a database instance, you will need to decide if you want to remove or keep the data in the database directory.



KeepOrRemoveDataDialog_New

Silent Installation

The MSI installer supports silent installations as well. In its simplest form silent installation with all defaults can be performed from an elevated command prompt like this:

```
msiexec /i path-to-package.msi /qn
```

> **Note:**
>
> The installation is silent due to msiexe.exe's /qn switch (no user interface). If you remove the switch, the installation has the full UI.

Properties

Silent installations also support installation properties (a property would correspond for example to checked/unchecked state of a checkbox in the UI, user password, etc). With properties the command line to install the MSI package would look like this:

```
msiexec /i path-to-package.msi [PROPERTY_1=VALUE_1 ... PROPERTY_N=VALUE_N] /qn
```

The MSI installer package requires property names to be all capitals and contain only English letters. By convention, for a boolean property, an empty value means "false" and a non-empty is "true".

MariaDB installation supports the following properties:

Property name	Default value	Description
INSTALLDIR	%ProgramFiles%\MariaDB \	Installation root
PORT	3306	–port parameter for the server
ALLOWREMOTEROOTACCESS		Allow remote access for root user
BUFFERPOOLSIZE	RAM/8	Bufferpoolsize for innodb

Property name	Default value	Description
CLEANUPDATA	1	Remove the data directory (uninstall only)
DATADIR	INSTALLDIR\data	Location of the data directory
DEFAULTUSER		Allow anonymous users
PASSWORD		Password of the root user
SERVICENAME		Name of the Windows service. A service is not created if this value is empty.
SKIPNETWORKING		Skip networking
STDCONFIG	1	Corresponds to “optimize for transactions” in the GUI, default engine innodb, strict sql mode
UTF8		if set, adds character-set-server=utf8 to my.ini file
PAGESIZE	16K	page size for innodb

Features

Feature is a Windows installer term for a unit of installation. Features can be selected and deselected in the UI in the feature tree in the “Custom Setup” dialog.

Silent installation supports adding features with the special property `ADDLOCAL=Feature_1,..,Feature_N` and removing features with `REMOVE=Feature_1,..., Feature_N` .

Features in the MariaDB installer:

Feature id	Installed by default?	Description
DBInstance	yes	Install database instance
Client	yes	Command line client programs
MYSQLSERVER	yes	Install server
SharedLibraries	yes	Install client shared library
DEVEL	yes	install C/C++ header files and client libraries
HeidiSQL	yes	Installs HeidiSQL

Silent Installation Examples

All examples here require running as administrator with elevated command line privileges.

- Install default features, database instance as service, non-default datadir and port:

```
msiexec /i path-to-package.msi SERVICENAME=MySQL DATADIR=C:\mariadb5.2\data PORT=3307 /qn
```

- Install service, add debug symbols, do not add development components (client libraries and headers).

```
msiexec /i path-to-package.msi SERVICENAME=MySQL ADDLOCAL=DEBUGSYMBOLS REMOVE=DEVEL /qn
```

Silent Uninstall

To uninstall silently, use the `REMOVE=ALL` property with msiexec:

```
msiexec /i path-to-package.msi REMOVE=ALL /qn
```

To keep the data directory during an uninstall, you will need to pass an additional parameter:

```
msiexec /i path-to-package.msi REMOVE=ALL CLEANUPDATA="" /qn
```

Installation Logs

If you encounter a bug in the installer, use the installer logs for diagnosis. Please attach verbose logs to the bug reports you create. To create a verbose installer log, start the installer from the command line with the `/l*v` switch, like so:

```
msiexec.exe /i path-to-package.msi  /l*v path-to-logfile.txt
```

Running 32 and 64 Bit Distributions on the Same Machine

It is possible to install 32 and 64 bit packages on the same Windows x64.

Apart from testing, an example where this feature can be useful is a development scenario, where users want to run a 64 bit server and develop both 32 and 64 bit client components. In this case the full 64 bit package can be installed, including a database instance plus development-related features (headers and libraries) from the 32 bit package.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB on macOS

MariaDB Server is available for installation on macOS via the Homebrew package manager. MariaDB Server (together with many client programs and helper tools) is available as a Homebrew “bottle”, a precompiled package. If you haven’t yet installed Homebrew, see this section.

Installing & Starting MariaDB

Install MariaDB Server:

```
brew install mariadb
```

> **Note:**
>
> This can take several minutes to complete, depending on hardware, network, and other factors.

Start MariaDB Server:

```
mysql.server start
```

Alternatively, and strongly recommended, automatically start MariaDB Server:

```
brew services start mariadb
```

> **Note:**
>
> Automatically starting MariaDB server installs a background service on macOS. Make sure to allow adding that background service. See this section for more information.

Connecting to MariaDB Server

After MariaDB Server has started, you can connect to the server using the shell user name (see this section for information on the user):

```
mariadb
```

Alternatively, connect as root:

```
sudo mysql -u root
```

For graphical clients you can use instead of the `mariadb` command-line client, see this section.

Upgrading MariaDB

Update Homebrew packages:

```
brew update
```

Then upgrade MariaDB Server:

```
brew upgrade mariadb
```

Notes & Further Information

Homebrew Installation

Install Homebrew like this:

1. Open a Terminal (`⌘ + Space` to open *Spotlight*, type *Terminal*).
2. Issue this command:
   `/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"`
   1. Alternatively, use the package installer (`.pkg` ; at the time of writing this, https://github.com/Homebrew/brew/releases/download/5.0.4/Homebrew-5.0.4.pkg)
3. Refer to the Homebrew website for more information, particularly to the Homebrew documentation.

MariaDB Configuration

In Homebrew, the configuration file for MariaDB is located at:

- `/usr/local/etc/my.cnf` for Intel-based Macs.
- `/opt/homebrew/etc/my.cnf` for Apple Silicon Macs (ARM architecture).

MariaDB Information

Find information about the MariaDB version, analytics, and more, using the `brew info` command:

```
~> brew info mariadb
==> mariadb: stable 12.1.2 (bottled)
Drop-in replacement for MySQL
https://mariadb.org/
...
To restart mariadb after an upgrade:
  brew services restart mariadb
Or, if you don't want/need a background service you can just run:
  /opt/homebrew/opt/mariadb/bin/mariadbd-safe --datadir\=/opt/homebrew/var/mysql
==> Analytics
install: 6,319 (30 days), 12,735 (90 days), 62,444 (365 days)
install-on-request: 6,291 (30 days), 12,670 (90 days), 62,137 (365 days)
build-error: 8 (30 days)
```

MariaDB Programs

MariaDB Server (`mariadbd`), the MariaDB command-line client (`mariadb`), and many more clients and tools are installed in `/opt/homebrew/Cellar/mariadb` (for Apple Silicon Macs). Find the location for your machine, as well as the MariaDB programs installed, with these commands:

```
~> which mariadb
/opt/homebrew/bin/mariadb # in the next command, use this location to cd to
~> cd /opt/homebrew/bin/; ls -1 maria*
mariabackup
mariadb
mariadb-access
...
mariadbd
mariadbd-multi
mariadbd-safe
mariadbd-safe-helper
```

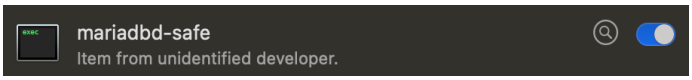
Terminal User & MariaDB User

To find out which user is used, issue these commands in a shell like *Terminal*:

```
~> users
myuser
~> mariadb -e "SELECT USER()"
+------------------+
| USER()           |
+------------------+
| myuser@localhost |
+------------------+
```

macOS Background Service

If you start MariaDB automatically, a macOS background service is added. You can find the MariaDB background service in `System Settings > General > Login Items & Extensions`. It's named `mariadbd-safe`.



The toggle switch allows you to turn off the automatic start of MariaDB. This prevents MariaDB Server from automatically starting once you reboot macOS.

To review the resource usage of MariaDB Server, use this command (type `q` to exit `top` when done):

```
top -pid $(pgrep mariadbd)
```

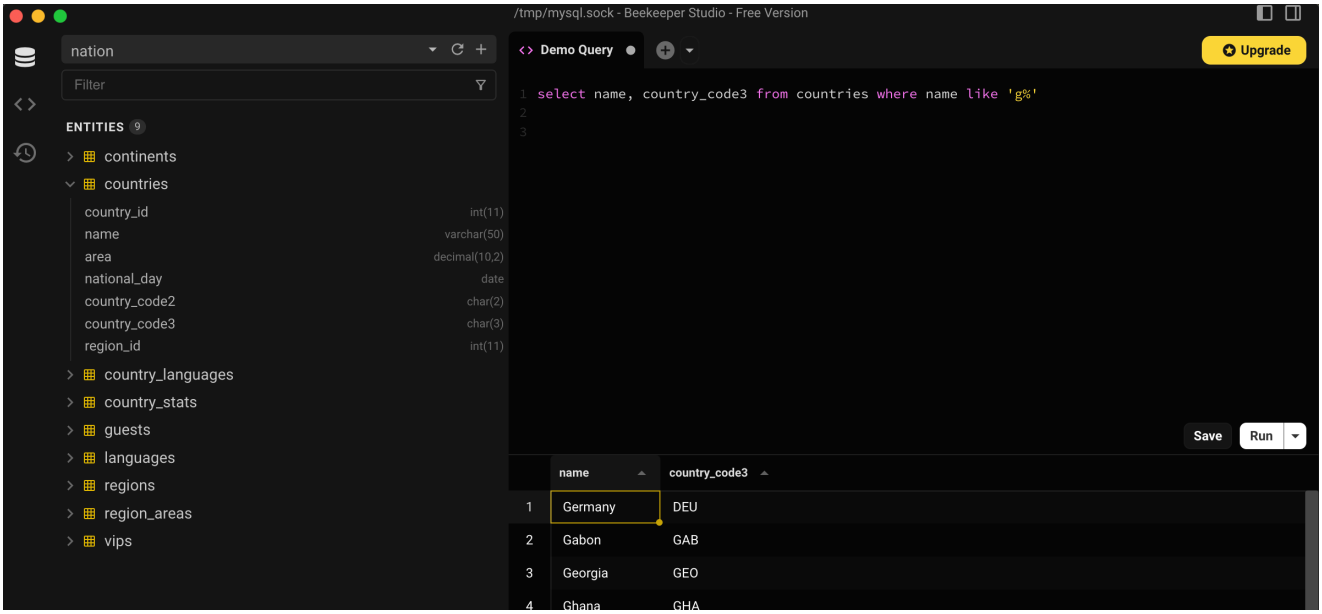
Graphical Clients

MariaDB doesn't offer graphical clients for working with MariaDB Server, but there are many third-party graphical clients, some of which run on macOS. One of those is Beekeeper Studio, a subscription-based client that has a (not too) limited free version, though.

Assuming a standard Homebrew installation of MariaDB, and assuming you connect to MariaDB Server using the standard shell user, configure Beekeeper Studio like this:

- Connection type: MariaDB
- Authentication method: Username/Password
- Connection mode: Socket
- Socket path: `/tmp/mysql.sock`
- Username: (name of the shell user, without the `@localhost` suffix)

Once connected to MariaDB Server, you can run queries in Beehive Studio:



The query shown in this screenshot uses a MariaDB sample database called *nation* which you can use to get familiar with MariaDB. See this section for more information.

MariaDB Sample Database

MariaDB offers a sample database you can use to get familiar with using MariaDB. You can download it here: https://mariadbtutorial.com/wp-content/uploads/2019/10/nation.zip

Unzip `nation.zip`, then import the database into MariaDB Server, using this command (assuming you downloaded and unzipped the sample database in the `Downloads` folder):

```
mariadb < Downloads/nation.sql
```

When done, use that database in the `mariadb` command-line client, like this:

```
~> mariadb nation
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 14
Server version: 12.1.2-MariaDB Homebrew

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [nation]> SHOW TABLES;
+------------------+
| Tables_in_nation  |
+------------------+
| continents        |
| countries         |
| country_languages |
| country_stats     |
| guests            |
| languages         |
| region_areas      |
| regions           |
| vips              |
+------------------+
9 rows in set (0.001 sec)
```

Alternatively, open the database in a graphical client.

Building MariaDB Server from source

In addition to the “bottled” MariaDB Server package available from Homebrew, you can use Homebrew to build MariaDB from source. This is useful if you want to use a different version of the server or enable some different capabilities that are not included in the bottle package.

Two components not included in the bottle package are the CONNECT and OQGRAPH engines, because they have non-standard dependencies. To build MariaDB Server with these engines, you must first install `boost` and `judy`. Follow these steps to install the dependencies and build the server:

```
brew install boost judy
brew install mariadb --build-from-source
```

You can also use Homebrew to build and install a pre-release version of MariaDB Server. Use this command to build and install a “development” version of MariaDB Server:

```
brew install mariadb --devel
```

Installing MariaDB on macOS (PKG)

MariaDB Server does not currently provide a `.pkg` installer for macOS. For information about how to install MariaDB Server on macOS using Homebrew, see Installing MariaDB Server on macOS Using Homebrew.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB Windows ZIP Packages

Users need to run mariadb-install-db.exe, without parameters to create a data directory, e.g

```
C:\zip_unpack\directory> bin\mariadb-install-db.exe
```

Then you can start server like this

```
C:\zip_unpack\directory> bin\mariadbd.exe --console
```

If you like to customize the server instance (data directory, install as service etc), please refer to mariadb-install-db.exe documentation

This page is licensed: CC BY-SA / Gnu FDL

Deploy with Package Tarballs

MariaDB Corporation provides package tarballs for some MariaDB database products.

Package tarballs provide multiple benefits:

- Package tarballs are compressed tar archives that contain software packages.
- Software packages can be installed using the operating system's package manager without relying on a remote repository.
- RPM (.rpm) files are distributed for CentOS, Red Hat Enterprise Linux (RHEL), and SUSE Linux Enterprise Server (SLES).
- DEB (.deb) files are distributed for Debian and Ubuntu.

If you want to deploy MariaDB database products without using a package tarball, alternative deployment methods are available. Available deployment methods are component-specific.

Use Cases

MariaDB database products can be deployed with package tarballs to support use cases, such as:

- Transfer the package tarball to an air-gapped network for installation without an internet connection
- Install software using a package manager without configuring a package repository
- Automatically install missing dependencies using a package manager

Compatibility

The following MariaDB database products can be deployed using package tarballs:

- MariaDB Community Server 10.5
- MariaDB Community Server 10.6
- MariaDB Enterprise Server 10.5
- MariaDB Enterprise Server 10.6
- MariaDB Enterprise Server 11.4
- MariaDB MaxScale 22.08

Download a Package Tarball

MariaDB Corporation provides package tarballs (.debs.tar, .rpms.tar) to support customers who leverage in-house package repositories to distribute software to their servers. Secure any such repository to prevent outside access.

MariaDB Corporation provides multiple interfaces to download package tarballs.

> **WEB BROWSER**

1. Visit the MariaDB Downloads page.
2. Complete customer login.
3. Select the desired version and operating system.
4. Click the Download button.

COMMAND LINE OR AUTOMATION

Package tarballs can be downloaded using command-line tools or automation from the MariaDB Download interface with the Customer Download Token.

For additional information, see "Download Binary Files".

Installation From Package Tarball

Once downloaded and extracted, you can:

- Install .rpm packages (RHEL, CentOS, and SLES): `rpm -i`
- Install .deb packages (Debian, Ubuntu): `dpkg -i`
- Install from the simple package repositories included in the tarball. Missing dependencies will be resolved when using the `apt`, `yum`, or `zypper` package manager.
  See the `README file` enclosed in the package tarball for more information.
- Test packages before placement in an internal package repository for distribution to your servers. Secure this repository from outside access.

Installation loads software to the system. This software requires configuration before the database server is ready for use.

This page is: Copyright © 2026 MariaDB. All rights reserved.

Deploy with Local Package Repository Mirrors

MariaDB Corporation provides package repositories, including the MariaDB Enterprise Repository and the MariaDB Community Repository, that can be used to install MariaDB products using the operating system's package manager. Local mirrors of the package repositories can be used for local deployments.

Local package repository mirrors provide multiple benefits:

- MariaDB Corporation's official package repositories are the source for the local mirror.
- Tools provided by the operating system are used to create and maintain the local mirror.
- After a local mirror is created, the mirror can be used just like the MariaDB repositories to install MariaDB products using the operating system's package manager.

If you want to deploy MariaDB database products without using a local package repository mirror, alternative deployment methods are available. Available deployment methods are component-specific.

Use Cases

MariaDB database products can be deployed with local package repository mirrors to support use cases, such as:

- Install from the mirror on an air-gapped network that is not connected to the internet
- Remove packages from mirror for versions that are not used in the local environment
- Add packages to mirror for tools and clients that are used in the local environment
- Automatically install missing dependencies using a package manager

Compatibility

The following MariaDB database products can be deployed using package repositories:

- MariaDB Community Server 10.6
- MariaDB Community Server 10.11
- MariaDB Community Server 11.4
- MariaDB Community Server 11.8
- MariaDB Community Server 12.3
- MariaDB Enterprise Server 10.6
- MariaDB Enterprise Server 11.4
- MariaDB Enterprise Server 11.8
- MariaDB MaxScale 23.02
- MariaDB MaxScale 23.08
- MariaDB MaxScale 24.02
- MariaDB MaxScale 25.01

Operating System Package Managers

The package manager depends on the operating system:

Operating System	Package Manager
Debian 11	APT
Debian 12	APT
Debian 13	APT
Red Hat Enterprise Linux 8 (RHEL 8)	DNF
Red Hat Enterprise Linux 9 (RHEL 9)	DNF
Red Hat Enterprise Linux 10 (RHEL 10)	DNF
Rocky Linux 8	DNF
Rocky Linux 9	DNF
Rocky Linux 10	DNF
SUSE Linux Enterprise Server 12 (SLES 12)	ZYpp
SUSE Linux Enterprise Server 15 (SLES 15)	ZYpp
Ubuntu 22.04 LTS (Jammy)	APT
Ubuntu 24.04 LTS (Noble)	APT

Create a Local Repository Mirror

Creating a local mirror of the MariaDB Enterprise Repository or the MariaDB Community Repository enables you to distribute MariaDB products to your servers from a local repository you support. Secure any such repository mirror to prevent outside access.

1. Configure a MariaDB repository
2. Set up a repository mirroring tool, for example:
   - YUM: `reposync`, available at: 23016
   - APT: `debmirror`, available at: Setup#Debian_Repository_Mirroring_Tools
3. Secure the repository mirror to prevent outside access.

Installing System Tables

See Installing System Tables on Unix.

Instructions for running the `mariadb-install-db` script on Unix-like systems to initialize the MariaDB data directory and system tables.

See Installing System Tables on Windows.

Details the use of `mariadb-install-db.exe` on Windows to create new database instances, set the root password, and register Windows services.

This page is licensed: CC BY-SA / Gnu FDL

Installing System Tables on Unix

`mariadb-install-db` initializes the MariaDB data directory and creates the system tables in the mysql database, if they do not exist. MariaDB uses these tables to manage privileges, roles, and plugins. It also uses them to provide the data for the help command in the mariadb client.

mariadb-install-db works by starting MariaDB Server's `mysqld` process in –bootstrap mode and sending commands to create the system tables and their content.

There is a version specifically for Windows, mysql_install_db.exe.

To invoke `mariadb-install-db`, use the following syntax:

```
mariadb-install-db --user=mysql
```

For the options supported by mariadb-install-db, see mariadb-install-db: Options.

For the option groups read by mariadb-install-db, see mariadb-install-db: Option Groups.

See mariadb-install-db: Installing System Tables for information on the installation process.

See mariadb-install-db: Troubleshooting Issues for information on how to troubleshoot the installation process.

See Also

- mariadb-install-db
- The Windows version of `mariadb-install-db`: mysql_install_db.exe

This page is licensed: CC BY-SA / Gnu FDL

Installing System Tables on Windows

The `mariadb-install-db.exe` utility is the Windows equivalent of mariadb-install-db.

Functionality

The functionality of `mariadb-install-db.exe` is comparable with the shell script `mariadb-install-db` used on Unix, however it has been extended with both Windows specific functionality (creating a Windows service) and to generally useful functionality. For example, it can set the 'root' user password during database creation. It also creates the `my.ini` configuration file in the data directory and adds most important parameters to it (e.g port).

`mariadb-install-db.exe` is used by the MariaDB installer for Windows if the "Database instance" feature is selected. It obsoletes similar utilities and scripts that were used in the past such as `mysqld.exe --install`, `mysql_install_db.pl`, and `mysql_secure_installation.pl`.

Parameter(s)	Description
`-?`, `--help`	Display help message and exit
`-d`, `--datadir=name`	Data directory of the new database
`-S`, `--service=name`	Name of the `Windows` service

Parameter(s)	Description
`-p`, `--password=name`	Password of the `root` user
`-P`, `--port=#`	`mysqld` port
`-W`, `--socket=name`	`named pipe` name
`-D`, `--default-user`	Create default user
`-R`, `--allow-remote-root-access`	Allow remote access from network for user `root`
`-N`, `--skip-networking`	Do not use `TCP` connections, use `pipe` instead
`-i`, `--innodb-page-size`	`Innodb` page size, since `MariaDB 10.2.5`
`-s`, `--silent`	Print less information
`-o`, `--verbose-bootstrap`	Include `mysqld` bootstrap output
`-l`, `--large-pages`	Use large pages, since `MariaDB 10.6.1`
`-c`, `--config`	`my.ini` config template file, since `MariaDB 10.6.1`

> **Note:**
>
> `--config` takes a **template** option file: `mariadb-install-db.exe` copies it into the data directory as `my.ini` and then appends the server settings it generates (such as `datadir` and `port`). The template must be a valid option file. Note that `config` is a command-line option of this tool, not a server variable, so it must not appear as a setting inside the template.

> **Note:**
>
> **T**o create a Windows service, `mariadb-install-db.exe` should be run by a user with full administrator privileges (which means elevated command prompt on systems with UAC).

Example

```
mariadb-install-db.exe --datadir=C:\db --service=MyDB --password=secret
```

will create the database in the directory `C:\db`, register the auto-start Windows service “MyDB”, and set the root password to ‘secret’.

To start the service from the command line, execute

```
sc start MyDB
```

Removing Database Instances

If you run your database instance as service, to remove it completely from the command line, use

```
sc stop <servicename>
sc delete <servicename>
rmdir /s /q <path-to-datadir>
```

This page is licensed: CC BY-SA / Gnu FDL

Troubleshooting Installation Issues

See Error: symbol mysql_get_server_name, version libmysqlclient_16 not defined.

Troubleshooting guide for a specific linker error involving `mysql_get_server_name` and `libmysqlclient_16`, typically occurring due to library version mismatches.

See Installation issues on Windows.

Guidance for dealing with glibc or shared library errors when attempting to install modern MariaDB binaries on older Linux distributions.

See Installation Issues on Debian and Ubuntu.

A collection of troubleshooting articles specific to Debian and Ubuntu deployments, covering upgrade failures, repository conflicts, and migration issues.

This page is licensed: CC BY-SA / Gnu FDL

Error: symbol mysql_get_server_name, version libmysqlclient_16 not defined

If you see the error message:

```
symbol mysql_get_server_name, version libmysqlclient_16 not defined in file libmysqlclient.so.16 with
link time reference
```

…then you are probably trying to use the mysql command-line client from MariaDB with `libmysqlclient.so` from MySQL.

The symbol `mysql_get_server_name()` is something present in the MariaDB source tree and not in the MySQL tree.

If you have both the MariaDB client package and the MySQL client packages installed this error will happen if your system finds the MySQL version of `libmysqlclient.so` first.

To figure out which library is being linked in dynamically (for instance, the wrong one) use the 'ldd' tool.

```
ldd $(which mysql) | grep mysql
```

or

```
ldd /path/to/the/binary | grep mysql
```

For example:

```
me@mybox:~$ ldd $(which mysql)|grep mysql
        libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb74df000)
```

You can then use your package manager's tools to find out which package the library belongs to.

On CentOS the command to find out which package installed a specific file is:

```
rpm -qf /path/to/file
```

On Debian-based systems, the command is:

```
dpkg -S /path/to/file
```

Here's an example of locating the library and finding out which package it belongs to on an Ubuntu system:

```
me@mybox:~$ ldd $(which mysql)|grep mysql
    libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb75f8000)
me@mybox:~$ dpkg -S /usr/lib/libmysqlclient.so.16
libmariadbclient16: /usr/lib/libmysqlclient.so.16
```

The above shows that the mysql command-line client is using the library `/usr/lib/libmysqlclient.so.16` and that library is part of the `libmariadbclient16` Ubuntu package. Unsurprisingly, the mysql command-line client works perfectly on this system.

If the answer that came back had been something other than a MariaDB package, then it is likely there would have been issues with running the MariaDB mysql client application.

If the library that the system tries to use is not from a MariaDB package, the remedy is to remove the offending package (and possibly install or re-install the correct package) so that the correct library can be used.

Installation issues on Windows

Unsupported Versions of Windows

Recent versions of MariaDB may not install on unsupported Windows versions. See Deprecated Package Platforms to find the final supported versions.

Systems with User Account Control

Running `mysql_install_db.exe` from a standard command prompt might cause the error:

```
FATAL ERROR: OpenSCManager failed
```

To get rid of it, use the elevated command prompt, for example on Windows 7 start it via 'Run as administrator' option.

This page is licensed: CC BY-SA / Gnu FDL

Installation Issues with PHP5

PHP5 may give an error if used with the old connect method:

```
'mysql_connect(): Headers and client library minor version mismatch. Headers:50156 Library:50206'
```

This is because the library wrongly checks and expects that the client library must be the exact same version as PHP was compiled with. You would get the same error if you tried to upgrade just the MySQL client library without upgrading PHP at the same time.

Ways to fix this issue:

1. Switch to using the mysqlnd driver in PHP (Recommended solution).
2. Run with a lower error reporting level:

```
$err_level = error_reporting(0);
$conn = mysql_connect('params');
error_reporting($err_level);
```

1. Recompile PHP with the MariaDB client libraries.
2. Use your original MySQL client library with the MariaDB.

This page is licensed: CC BY-SA / Gnu FDL

Installing on an Old Linux Version

This article lists some typical errors that may happen when you try to use an incompatible MariaDB binary on a linux system:

The following example errors are from trying to install MariaDB built for SuSE 11.x on a SuSE 9.0 server:

```
> scripts/mysql_install_db
./bin/my_print_defaults: /lib/i686/libc.so.6:
  version `GLIBC_2.4' not found (required by ./bin/my_print_defaults)
```

and

```
> ./bin/mysqld --skip-grant &
./bin/mysqld: error while loading shared libraries: libwrap.so.0:
cannot open shared object file: No such file or directory
```

If you see either of the above errors, the binary MariaDB package you installed is not compatible with your system.

The options you have are:

- Find another MariaDB package or tar from the download page that matches your system.
- Alternatively, download the source and build it.

This page is licensed: CC BY-SA / Gnu FDL

Installation Issues on Debian and Ubuntu

See apt-upgrade Fails, But the Database is Running.

Solutions for when `apt-get upgrade` hangs or fails because the MariaDB service takes too long to start, triggering a timeout in the init script.

See Differences in MariaDB in Debian (and Ubuntu).

Explains the differences between official Debian/Ubuntu repository packages and those from MariaDB.org, particularly regarding library linking and configuration defaults.

This page is licensed: CC BY-SA / Gnu FDL

apt-upgrade Fails, But the Database is Running

After running `apt-upgrade mariadb`, it's possible that apt shows a fail in trying to start the server, but in fact the database is up and running, which then provokes apt to remain in a non finished state.

For example:

```
# apt-get upgrade
Reading package lists... Done
Building dependency tree
Reading state information... Done
Calculating upgrade... Done
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
2 not fully installed or removed.
After this operation, 0 B of additional disk space will be used.
Do you want to continue? [Y/n]
Setting up mariadb-server-10.1 (10.1.10+maria-1~trusty) ...
 * Stopping MariaDB database server mysqld
   ...done.
 * Starting MariaDB database server mysqld
   ...fail!
invoke-rc.d: initscript mysql, action "start" failed.
dpkg: error processing package mariadb-server-10.1 (--configure):
 subprocess installed post-installation script returned error exit status 1
dpkg: dependency problems prevent configuration of mariadb-server:
 mariadb-server depends on mariadb-server-10.1 (= 10.1.10+maria-1~trusty); however:
  Package mariadb-server-10.1 is not configured yet.

dpkg: error processing package mariadb-server (--configure):
 dependency problems - leaving unconfigured
No apport report written because the error message indicates its a followup error from a previous
failure.
Errors were encountered while processing:
 mariadb-server-10.1
 mariadb-server
E: Sub-process /usr/bin/dpkg returned an error code (1)
```

This situation could occur if the timeout for the init script was too short. For example, see MDEV-9382, a situation where the timeout was 30 seconds, but the server was taking 48 seconds to start.

To overcome this, the timeout needs to be increased. This can be achieved as follows:

- On systems where `systemd` is not `enabled/supported`: The timeout can be increased by setting `MYSQLD_STARTUP_TIMEOUT` either directly in the script or via the command line. The init script also sources `/etc/default/mariadb`, so it can also be used to set `MYSQLD_STARTUP_TIMEOUT` to persistently change the startup timeout.
- On systems that support `systemd`: The startup timeout can be increased by setting TimeoutStartSec systemd option.

This page is licensed: CC BY-SA / Gnu FDL

Differences in MariaDB in Debian (and Ubuntu)

The .deb packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are not identical to the official .deb packages provided by Debian's and Ubuntu's default repositories.

The packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are generated using the Debian packaging in MariaDB's official source code. The Debian packaging scripts are specifically in the `debian/` directory.

The packages provided by Debian's and Ubuntu's default repositories are generated using the Debian packaging in Debian's mirror of MariaDB's source code, which contains some custom changes. The source tree can be found here:

- mariadb-server

As a consequence, MariaDB behaves a bit differently if it is installed from Debian's and Ubuntu's default repositories.

Option File Locations

- The option file located at `/etc/mysql/my.cnf` is handled by the update-alternatives mechanism when the `mysql-common` package is installed. It is a symbolic link that references either `mysql.cnf` or `mariadb.cnf` depending on whether MySQL or MariaDB is installed. Most of the MariaDB option files are therefore actually located in `/etc/mysql/mariadb.d/`.

System Variables

Since MariaDB 11.6 there is no system variable difference from the Standard MariaDB.

Variable	MariaDB in Debian	Standard MariaDB	Notes
character_set_server	utf8mb4	latin1 (for <= MariaDB 11.5)	MariaDB 11.6 also defaults to utf8mb4 hence no difference for this version and greater
collation_server	utf8mb4_general_ci (for < MariaDB 11.5.2)	latin1_swedish_ci	character_set_collations has dominant effect hence removal from Debian default settings

Options

Option	MariaDB in Debian	Standard MariaDB	Notes
plugin-load-add	auth_socket.so	-	Before MariaDB 10.4.3, MariaDB did not enable the unix_socket authentication plugin by default.This is default in Debian, allowing passwordless login.

TLS

- MariaDB binaries from .deb packages provided by Debian's and Ubuntu's default repositories are linked with a different TLS library than MariaDB binaries from .deb packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.
- MariaDB Server binaries:
  - MariaDB Server is statically linked with the bundled wolfSSL libraries in .deb packages provided by Debian's and Ubuntu's default repositories.
  - In contrast, MariaDB Server is dynamically linked with the system's OpenSSL libraries in .deb packages provided by MariaDB Foundation and MariaDB Corporation.
- MariaDB client and utility binaries:
  - MariaDB's clients and utilities and MariaDB Connector/C are dynamically linked with the system's GnuTLS libraries in .deb packages provided by Debian's and Ubuntu's default repositories. libmysqlclient is still statically linked with the bundled wolfSSL libraries.
  - MariaDB's clients and utilities and MariaDB Connector/C are dynamically linked with the system's GnuTLS libraries in .deb packages provided by Debian's and Ubuntu's default repositories. libmysqlclient is still statically linked with the bundled yaSSL libraries.
  - In contrast, MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL libraries in .deb packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.
- See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

Authentication

- The unix_socket authentication plugin is installed by default in new installations that use the .deb packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later.

- The `root@localhost` created by mariadb-install-db will also be created to authenticate via the unix_socket authentication plugin in these builds.

Installing MariaDB on IBM Cloud

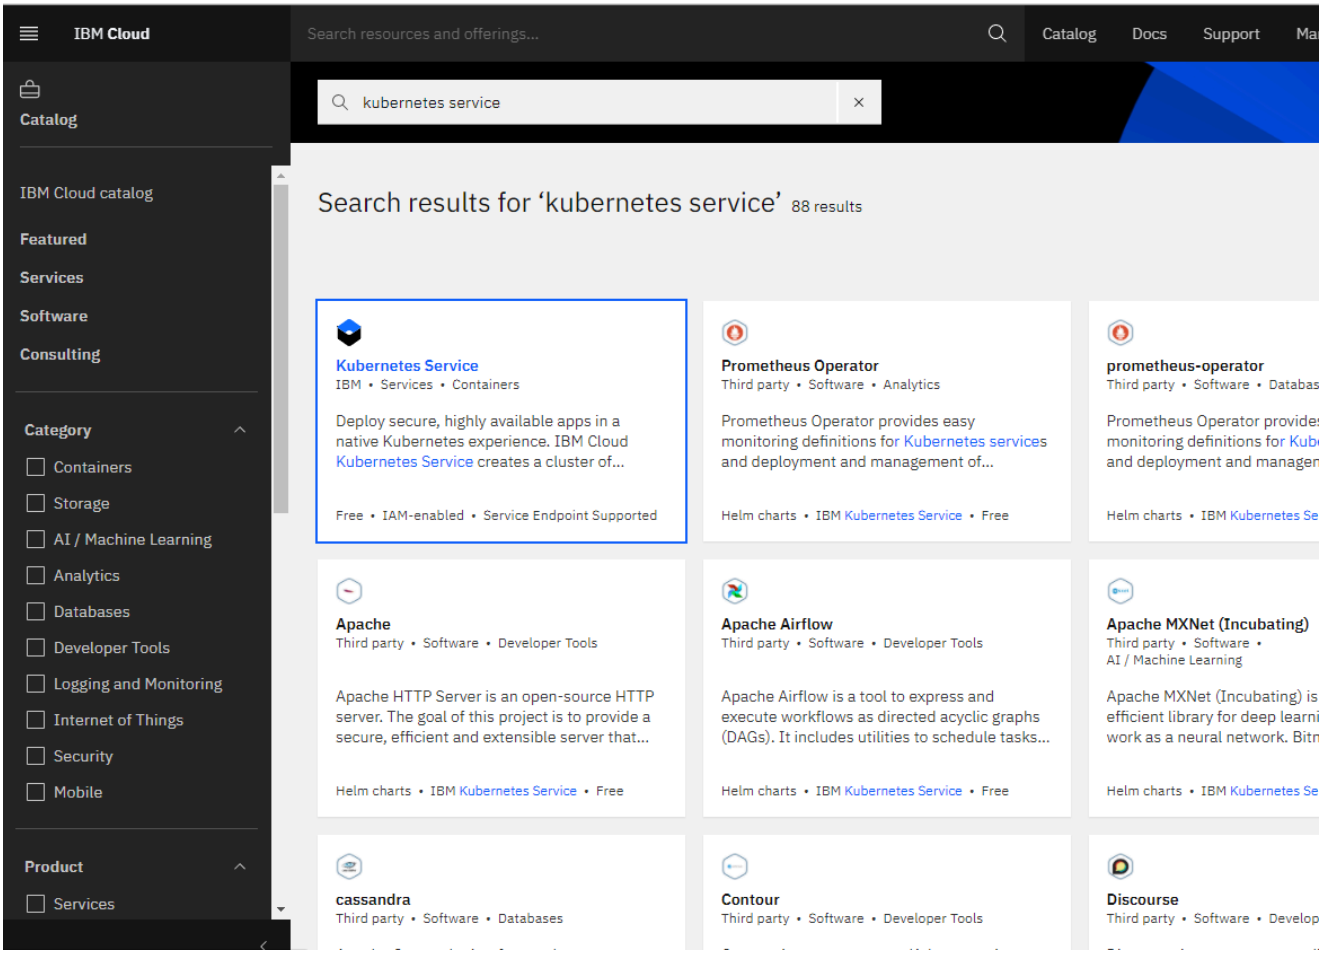
Get MariaDB on IBM Cloud.

You should have an IBM Cloud account, otherwise you can register here.
At the end of the tutorial you will have a cluster with MariaDB up and running. IBM Cloud uses Bitnami charts to deploy MariaDB on with helm

1. We will provision a new Kubernetes Cluster for you if, you already have one skip to step **2**
2. We will deploy the IBM Cloud Block Storage plug-in, if already have it skip to step **3**
3. MariaDB deployment

Step 1 provision Kubernetes Cluster

1. Click the Catalog button on the top.
2. Select Service from the catalog.
3. Search for Kubernetes Service and click on it.

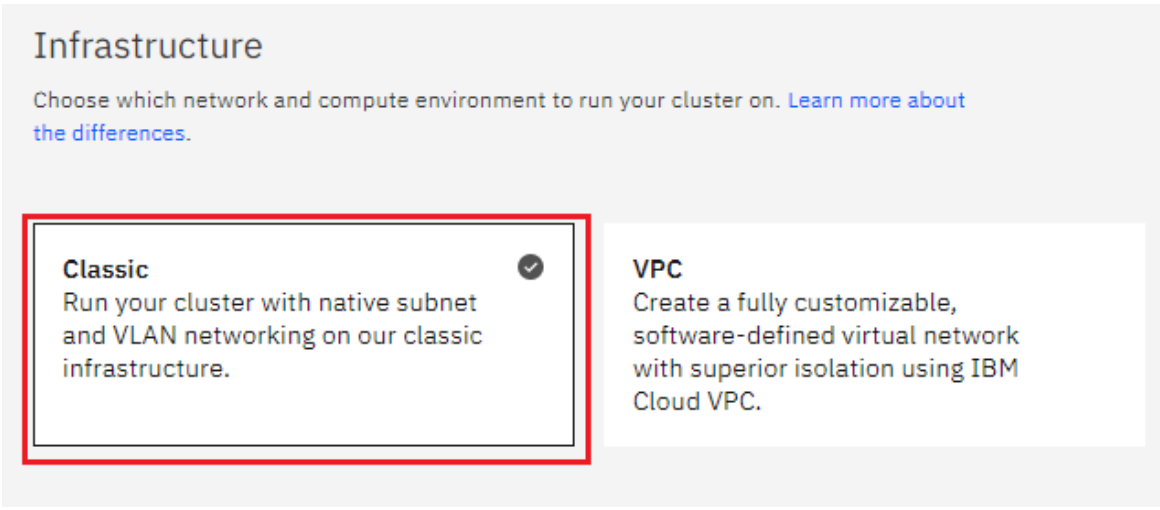


kubernetes-select

4. Choose a plan: standard or free.

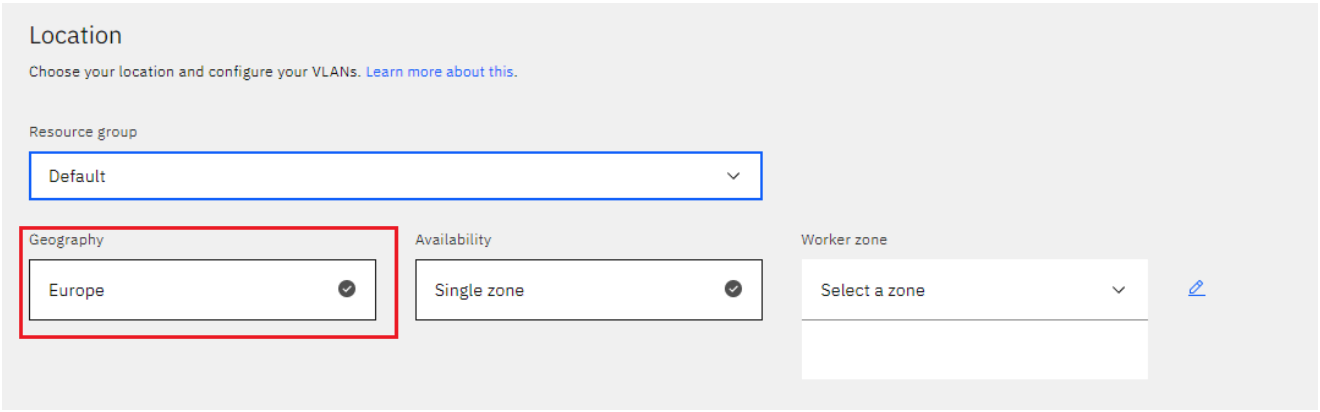
> **Note:**
>
> The free plan includes one worker node and no subnet.

5. To provision a standard cluster, upgrade your account to Pay-As-You-Go.
6. To upgrade to a Pay-As-You-Go account, follow these steps:
    1. In the console, go to **Manage > Account**.
    2. Select **Account settings**, and click **Add credit card**.
    3. Enter your payment information, click **Next**, and submit your information.
7. Choose between classic or VPC after reviewing the documentation to determine the most suitable option.



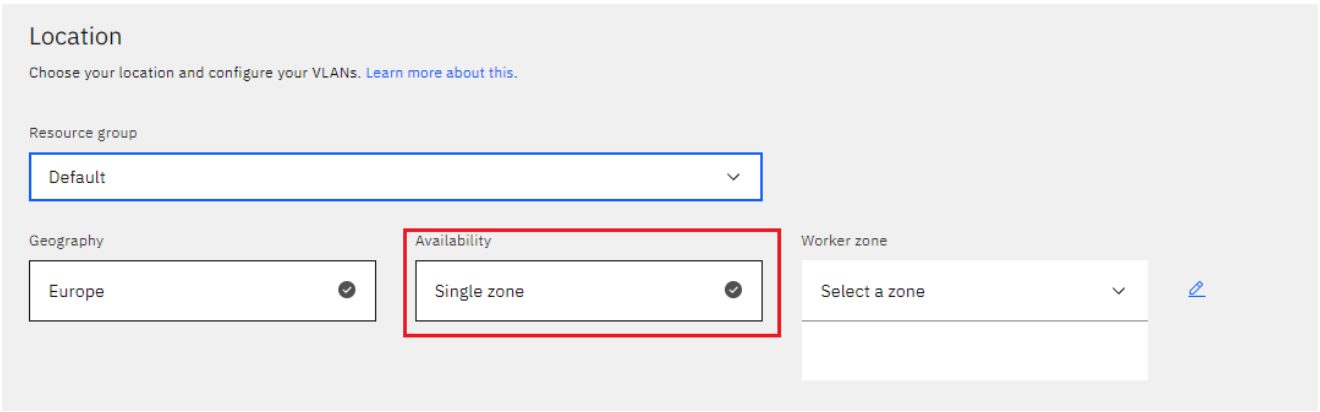
infra-select

8. Now choose your location settings, for more information please visit Locations
9. Choose **Geography** (continent)



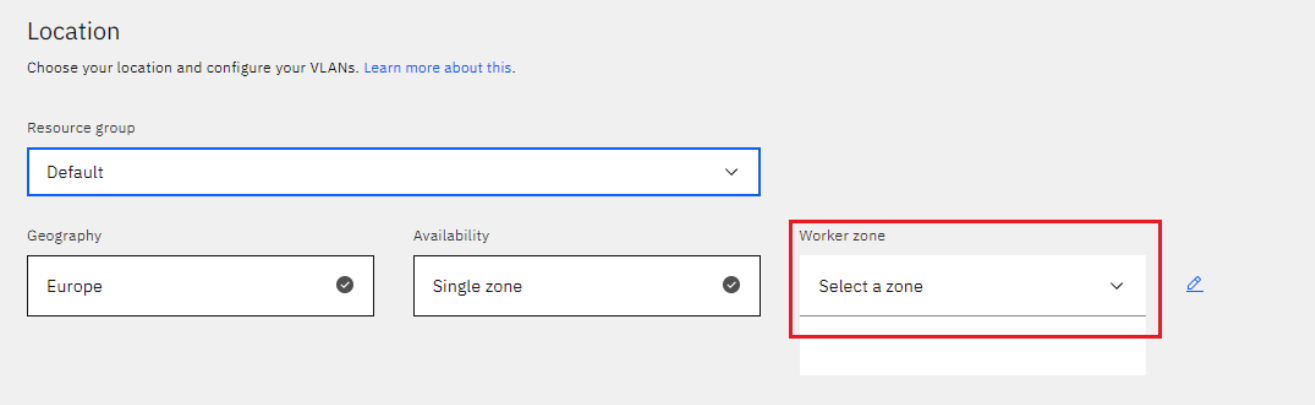
location-geo

10. Select either **Single-Zone** or **Multi-Zone** storage. Single Zone stores your data in one data center, while Multi-Zone distributes your data across multiple zones, offering greater safety in the event of unexpected zone failures.



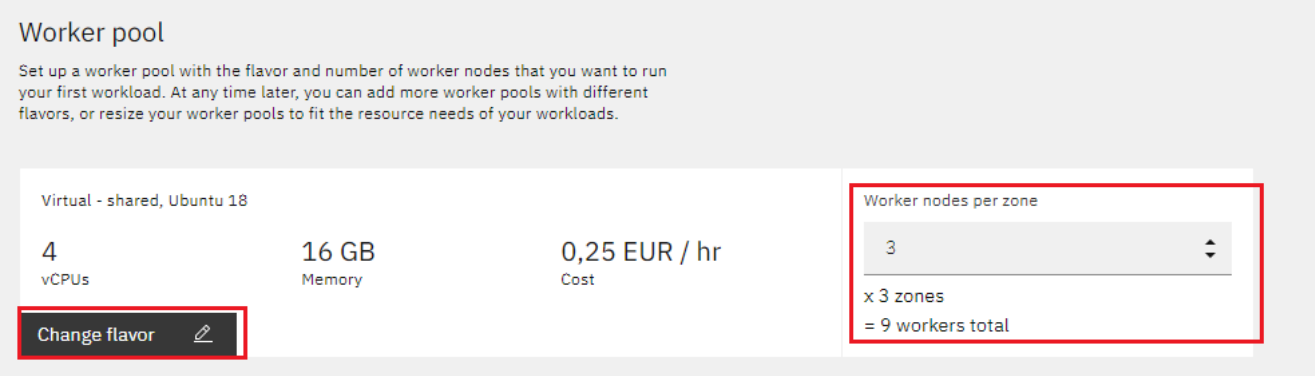
location-avail

11. Choose a **Worker Zone** if using Single zones or Metro if Multizone



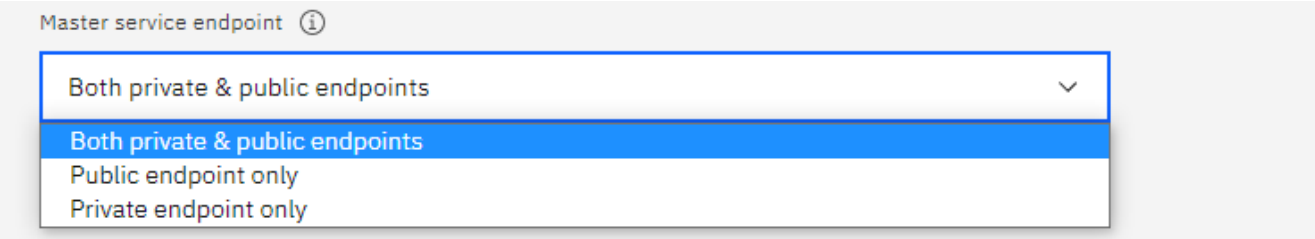
location-worker

12. Set up your account with VRF or enable VLAN spanning to use Multizone.
13. If no Virtual LAN is available at your selected location, a new VLAN will be created for you.
14. Choose a Worker node setup or use the preselected one.
15. Set the **Worker node per zone**.



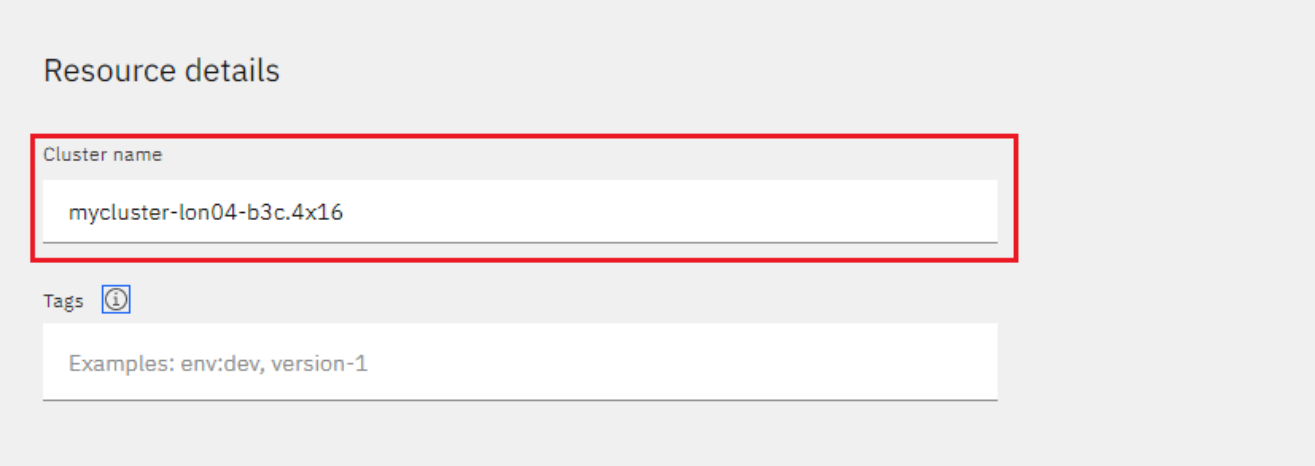
worker-pool

16. Choose Master Service Endpoint, In VRF-enabled accounts, you can choose **Private endpoint only** to make your master accessible on the private network or via VPN tunnel. Choose **Public endpoint only** to make your master publicly accessible. When you have a VRF-enabled account, your cluster is set up by default to use **Both private and public endpoints**. For more information visit endpoints.



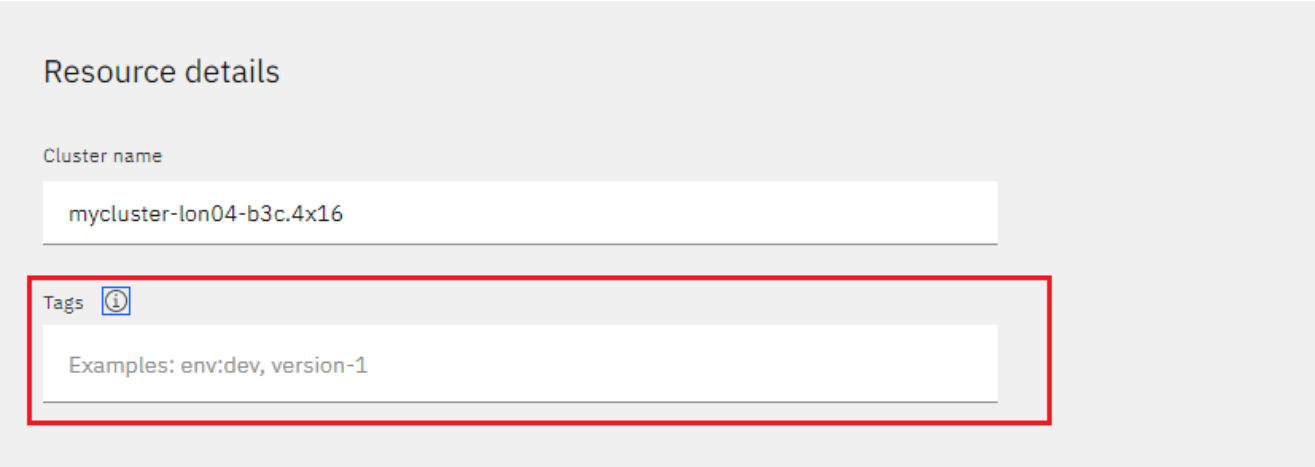
endpoints

17. Give **Cluster name**



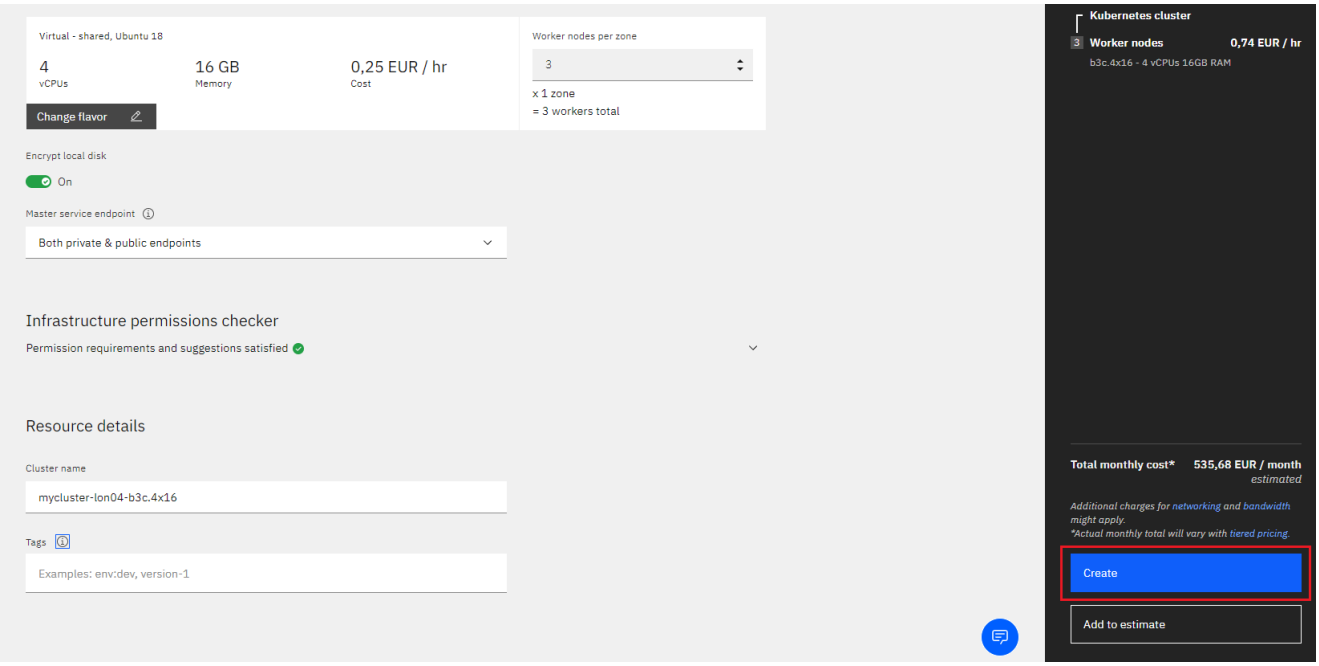
name-new

18. Give desired **Tags** to your cluster, for more information visit tags



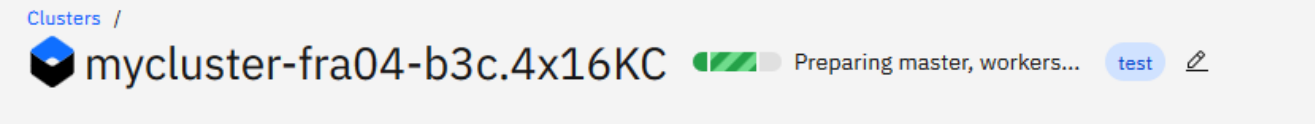
tasg-new

19. Click **Create**



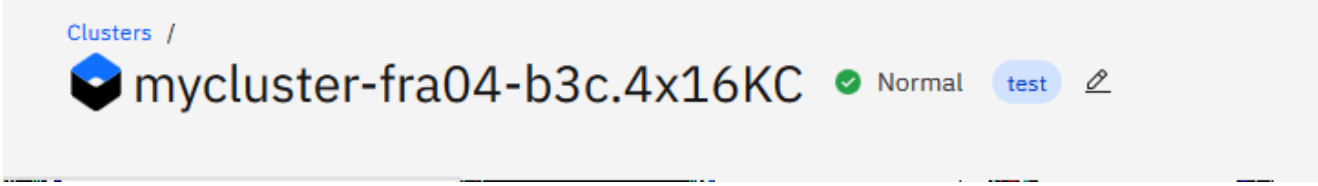
create-new

20. Wait for you cluster to be provisioned



cluster-prepare

21. Your cluster is ready for usage

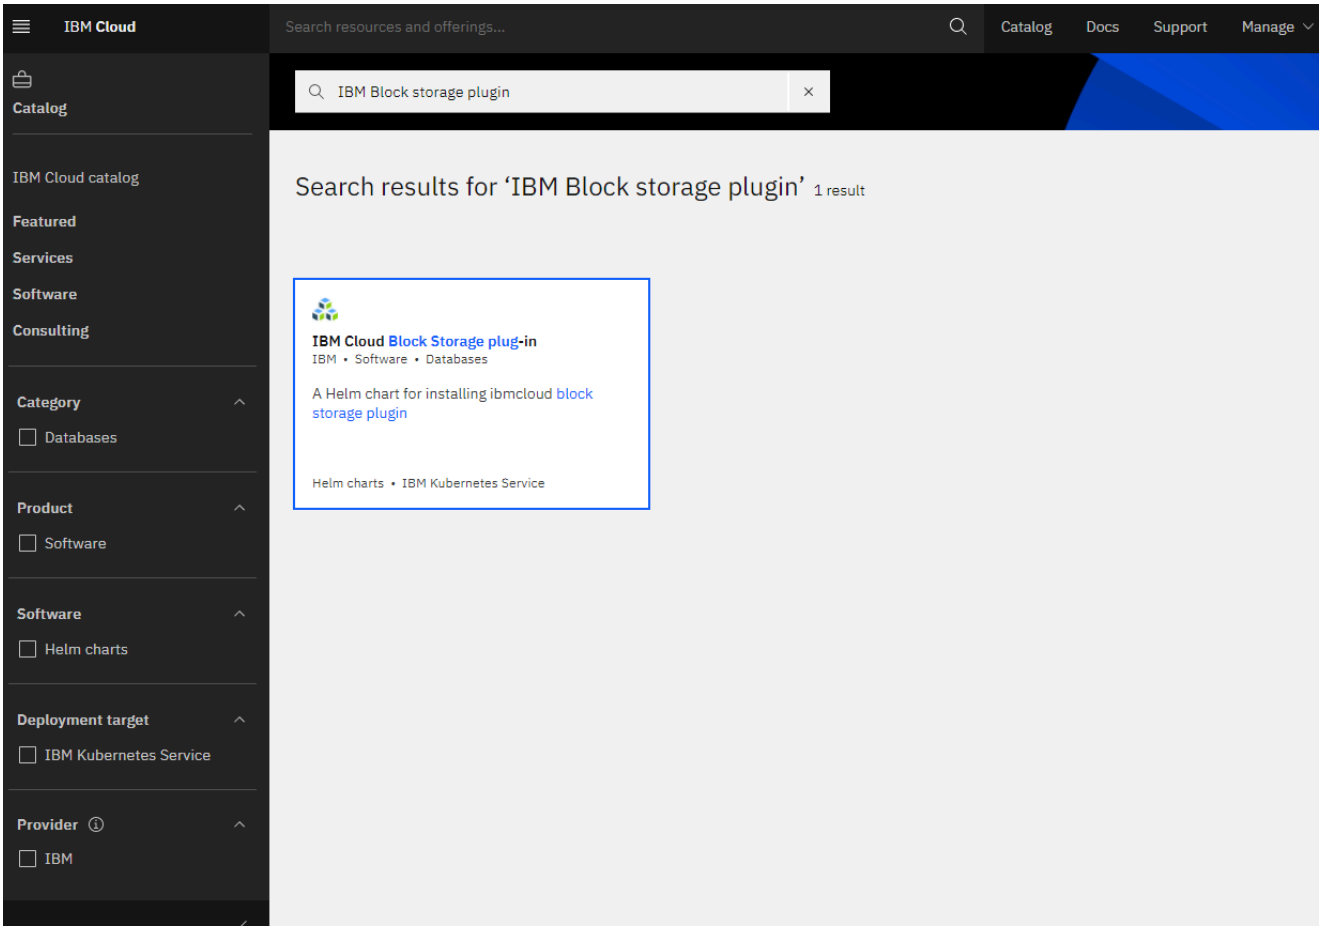


cluster-done

Step 2 deploy IBM Cloud Block Storage plug-in

The Block Storage plug-in is a persistent, high-performance iSCSI storage that you can add to your apps by using Kubernetes Persistent Volumes (PVs).

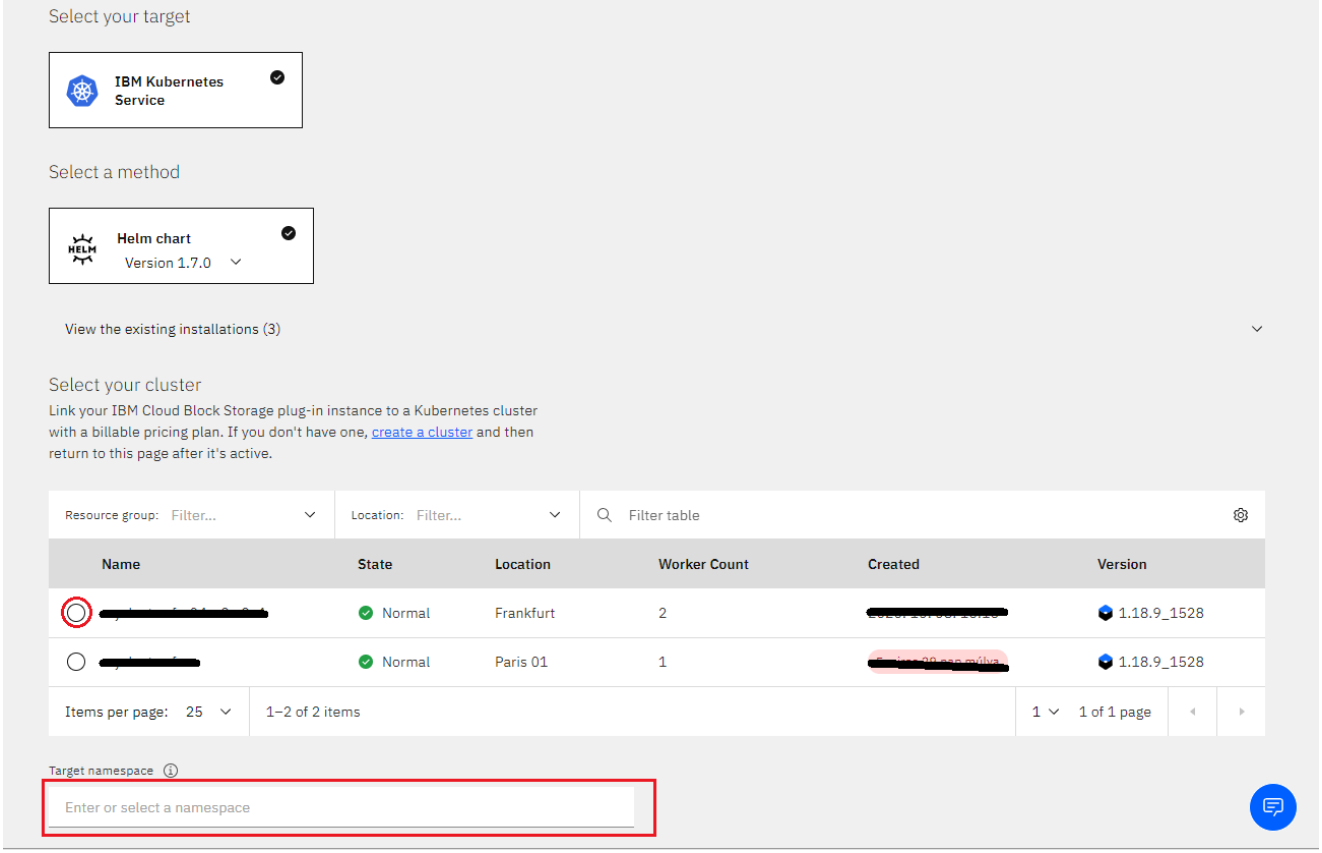
1. Click the **Catalog** button on the top
2. Select **Software** from the catalog
3. Search for *IBM Cloud Block Storage plug-in* and click on it



block-search

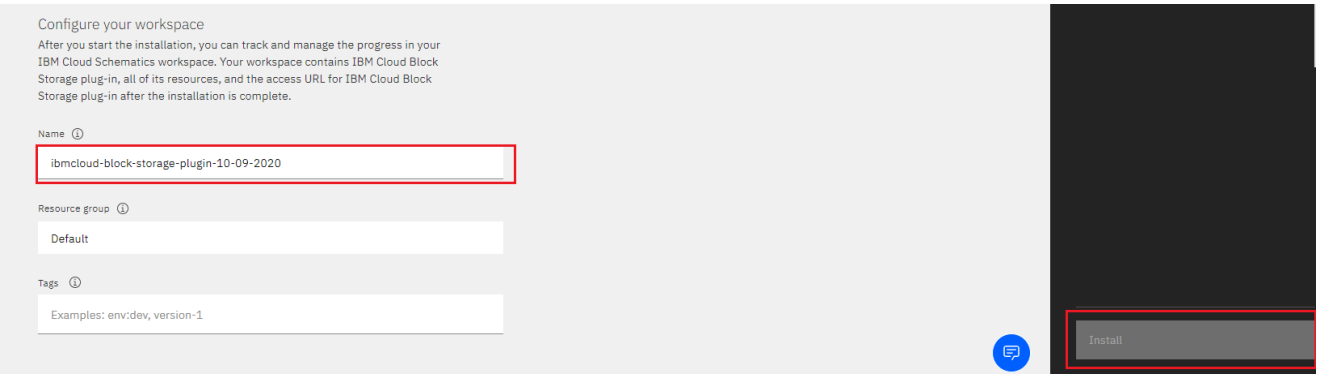
4. On the application page, select the cluster you wish to use

5. Click on **Enter or select namespace** and choose the default Namespace or use a custom one (if you get error please wait 30 minutes for the cluster to finalize)



block-cluster

6. Give a **Name** to this workspace
7. Click **Install** and wait for the deployment



block-storage-create

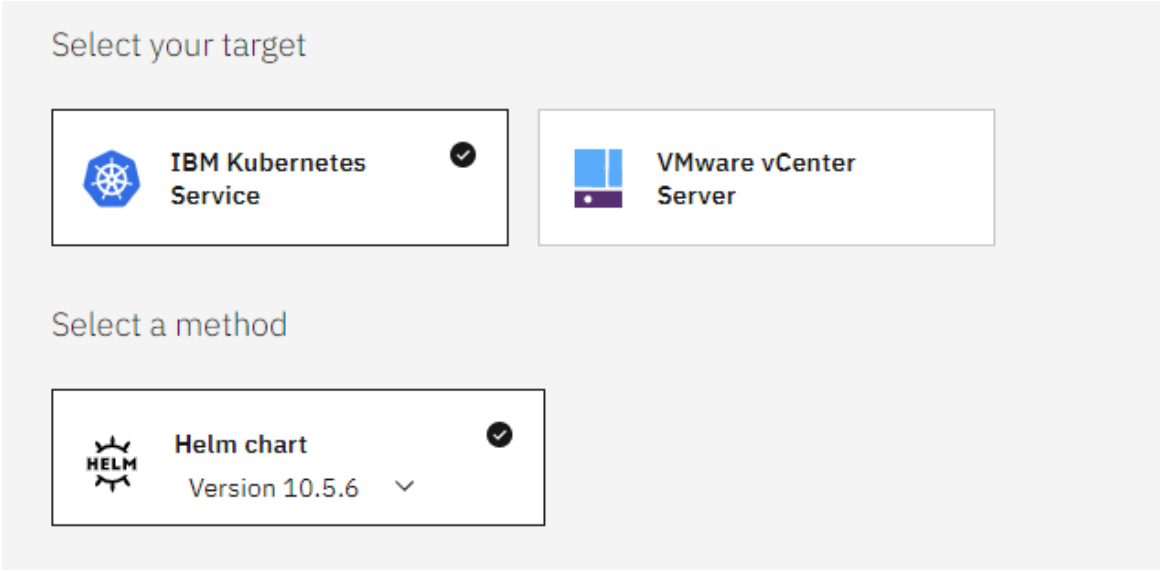
Step 3 deploy MariaDB

We will deploy MariaDB on our cluster

1. Click the **Catalog** button on the top
2. Select **Software** from the catalog
3. Search for *MariaDB* and click on it

search

4. Please select **IBM Kubernetes Service**



target-select

5. On the application page, select the cluster you wish to use

cluster-select

6. Click on **Enter or select namespace** and choose the default Namespace or use a custom one

details-namespace

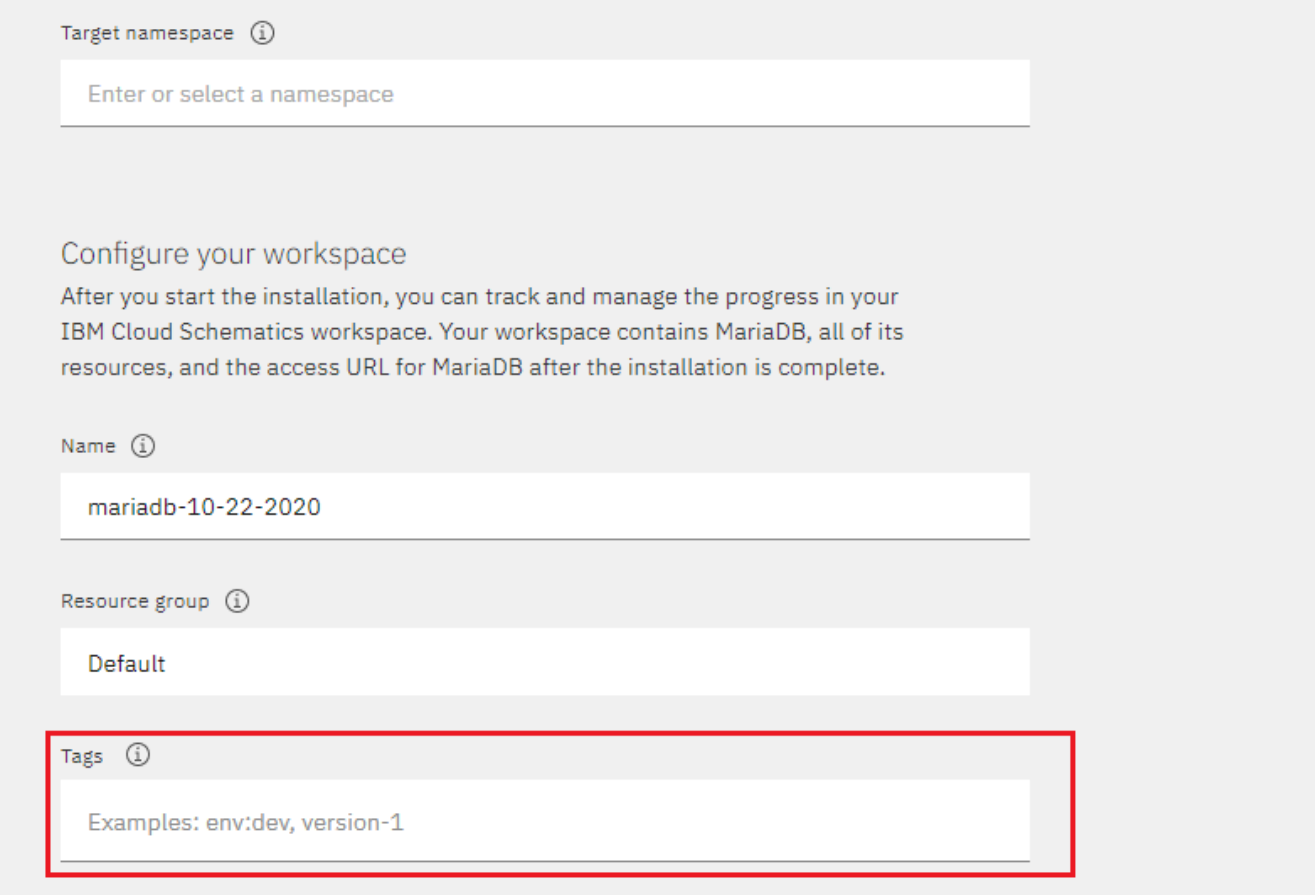
7. Give a unique name to workspace, which you can easily recognize

details-name

8. Select which **Resource Group** you want to use, it's for access control and billing purposes. For more information please visit resource groups

details-resource

9. Give **Tags** to your MariaDB, for more information visit tags

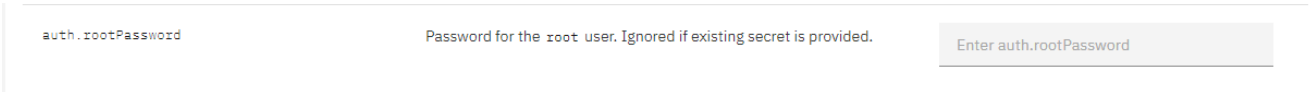


details-tags

10. Click on **Parameters with default values**, You can set deployment values or use the default ones

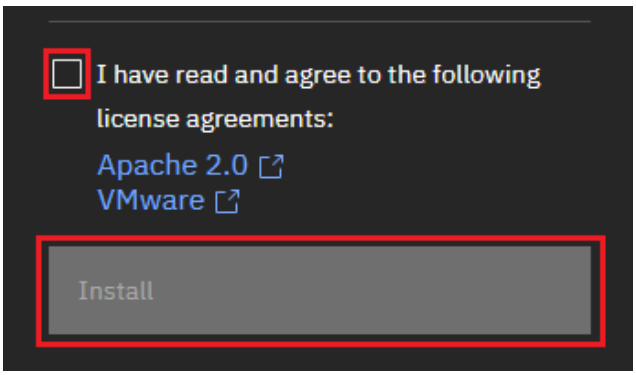
parameters

11. Please set the MariaDB root password in the parameters



root-password

12. After finishing everything, tick the box next to the agreements and click **Install**



aggreement-create

13. The MariaDB workspace will start installing, wait a couple of minutes

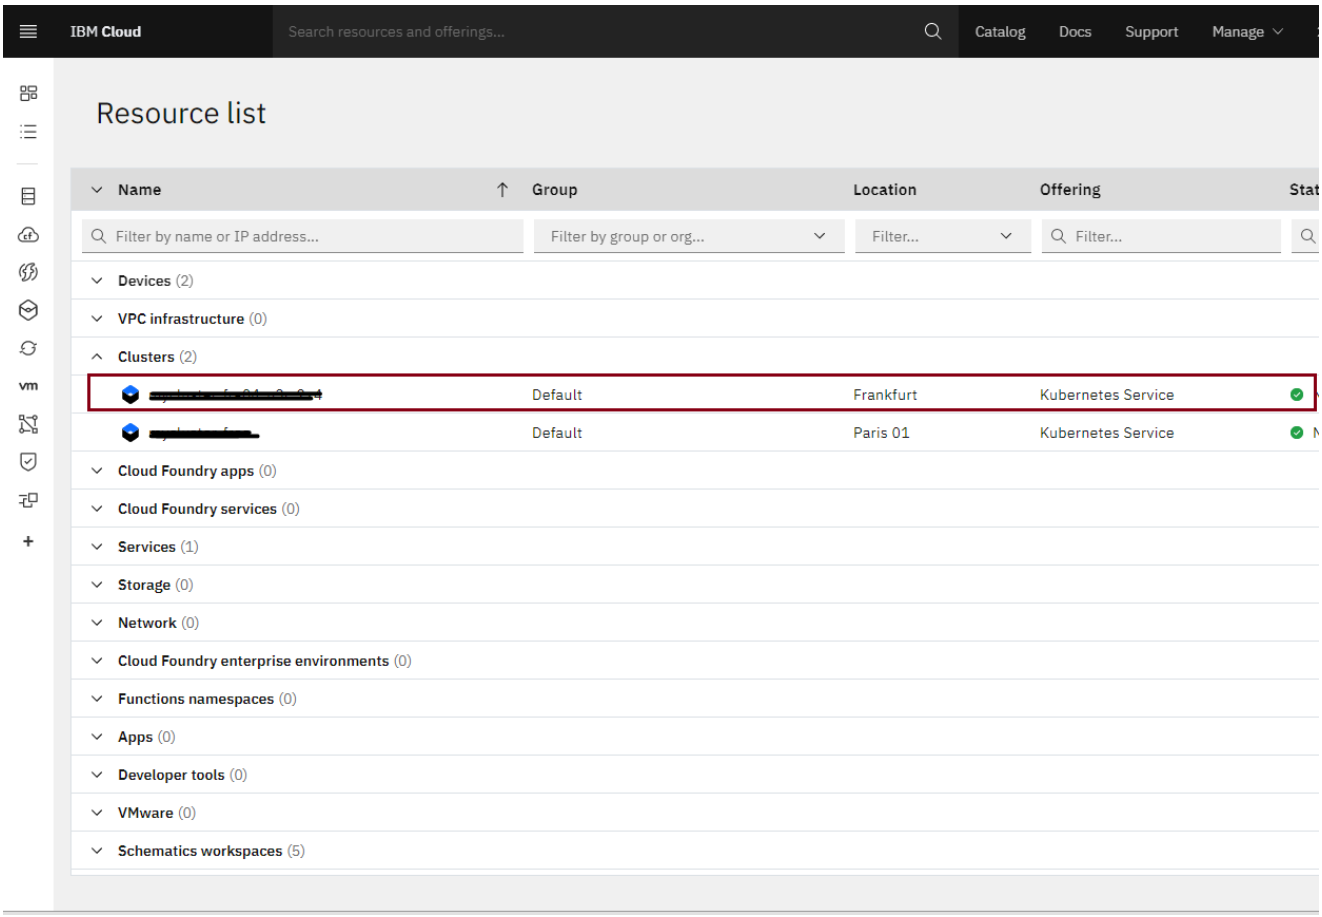
in-progress

14. Your MariaDB workspace has been successfully deployed

done

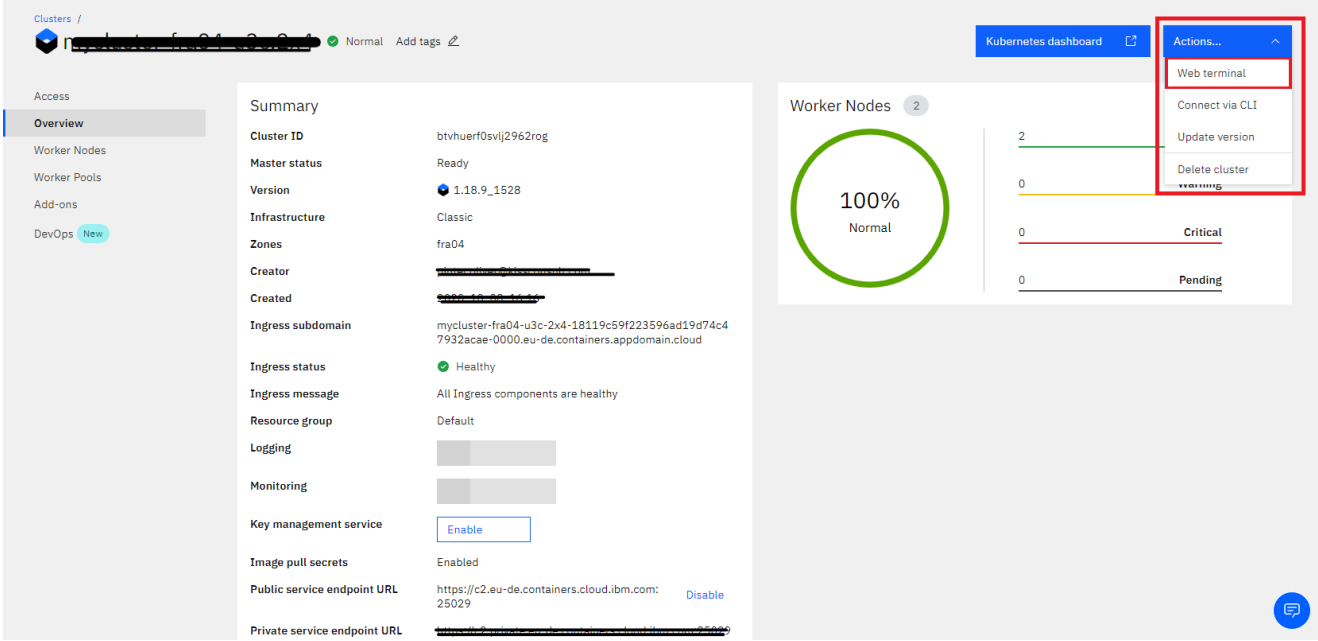
Verify MariaDB installation

1. Go to Resources in your browser
2. Expand **Clusters.** Click on your cluster



resource-select

3. On the **Overview** page, click **Actions**, then select **Web Terminal** from the dropdown menu.



cluster-main

4. Click Install and wait for sometime
5. Click on Actions
6. Click Web terminal. A terminal window will open up
7. On the terminal window, please change NAMESPACE to the namespace you choose at the deployment setup:

```
$ kubectl get ns
```

get-ns

```
$ kubectl get pod -n NAMESPACE -o wide
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl get pods -n mariadb -o wide
NAME                 READY   STATUS    RESTARTS   AGE   IP              NODE            NOMINATED NODE   READINESS GATES
mariadb2f-c27f-41-0  1/1     Running   0          21m   172.30.40.152   10.240.129.19   <none>           <none>
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$
```

get-pods

```
$ kubectl get service -n NAMESPACE
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl get service -n mariadb
NAME               TYPE        CLUSTER-IP       EXTERNAL-IP   PORT(S)    AGE
mariadb2f-c27f-41  ClusterIP   172.21.247.125   <none>        3306/TCP   22m
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$
```

get-service

8. Enter your pod with bash, please replace PODNAME with your mariadb pod's name

```
$ kubectl exec --stdin --tty PODNAME -n NAMESPACE -- /bin/bash
```

bash

9. After you are in your pod please enter Mariadb and enter your root password after the prompt

```
$ mysql -u root -p
```

welcome

You have successfully deployed MariaDB IBM Cloud!

Compiling MariaDB From Source: The Master Guide

> **Note:**
>
> This guide covers compiling MariaDB on Unix-like systems, including Linux and macOS. If you are building on Windows, please refer to the dedicated Building MariaDB on Windows guide.

This guide provides the universal workflow for building MariaDB Server from source code. While specific dependencies may vary by operating system, the core build process remains consistent across all modern platforms.

Major Steps

> **Step 1**
>
> **Prepare Your Environment**
>
> Before you begin, your system must have the necessary compilers, build tools, and library headers.
>
> > For details, see Install Build Dependencies.

Step 2

Obtain the Source Code

Decide whether you need the latest development branch or a specific stable release.

- Option A: Git clone (best for developers)

```
git clone --branch 11.8 https://github.com/MariaDB/server.git
cd server
```

- Option B: Source tarball (best for stability)

  Download the `.tar.gz` from the official MariaDB downloads and extract it:

```
tar -xf mariadb-11.8.x.tar.gz
cd mariadb-11.8.x
```

> For details on both options, see Obtaining the Source Code.

Step 3

Configure the Build (CMake)

MariaDB uses out-of-source builds to keep the source tree clean. This is where you define installation paths and features.

1. Create a build directory: `mkdir build && cd build`
2. Run CMake:

```
cmake .. -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

   - *Common flags like `-DCMAKE_INSTALL_PREFIX` or debug options go here.*

> For common CMake configuration flags, see Common CMake Configuration Flags.
>
> For a configuration alternative to configuring CMake, see The Quick Way: Using BUILD Scripts.

Step 4

Compile

Once configured, use the CMake build tool to compile the binaries. Using the `--parallel` flag speeds this up by using multiple CPU cores.

LINUX

```
cmake --build . --parallel $(nproc)
```

MACOS

```
cmake --build . --parallel $(sysctl -n hw.logicalcpu)
```

UNIVERSAL

For CMake 3.13+, run this:

```
cmake --build . --parallel
```

Without a number, modern CMake automatically picks an appropriate number of jobs.

> If you encounter build errors, see Troubleshooting Common Build Errors.

Step 5

Install and Initialize

After a successful build, you must prepare the data directory and system tables before the server can start.

1. Install: `sudo cmake --install .` (or run directly from the build directory for testing).
2. Create Data Directory: Ensure the `mysql` user exists and has permissions.
3. Initialize System Tables.
    1. If running from the build directory (use this if you did *not* run the `cmake` install command – in that case, you must run the script from within your build folder):

        ```
        ./scripts/mariadb-install-db --user=mysql --datadir=[path]
        ```

    2. If you installed to the system (`sudo cmake --install ...`, in which case the `PATH` to `mariadb-install-db` is set):

        ```
        mariadb-install-db --user=mysql --datadir=[path]
        ```

> See this section for conventional locations of the data directory (`--datadir`).

Step 6

Start and Verify

Launch the server and check that it is responsive.

```
./bin/mariadbd-safe --user=mysql &
./bin/mariadb -u root -p
```

> **Step 7**
>
> **Test the Build**
>
> Before putting your fresh build into production, verify it against the official test suite. MariaDB includes MTR (MariaDB Test Run) for this purpose.
>
> 1. Run Unit Tests: Quickly check the core logic.
>
>    ```
>    cmake --build . --target test
>    ```
>
> 2. Run Integration Tests (MTR): This launches actual server instances and runs thousands of SQL tests.
>
>    ```
>    cd mysql-test
>    ./mysql-test-run.pl --parallel=$(nproc)
>    ```
>
>   - Pro-Tip: If a specific test fails, you can run it individually: `./mysql-test-run.pl alias`.
>   - Note: You do not need to install MariaDB to the system to run these tests; they run entirely within the build directory.

> **Step 8**
>
> **After Building**
>
> After successfully building MariaDB from source, additional tasks can be found under Post-Build.

Summary of the Build Workflow

Step	Action	Primary Tool
1	Install Build Tools	`apt` / `dnf` / `brew`
2	Download Source	`git` / `wget`
3	Configure Features	`cmake`
4	Compile Binaries	`cmake --build`
5	Initialize Database	`mariadb-install-db`

Preparing Your Environment: Install Build Dependencies

> This section covers the details of step 1 (Prepare Your Environment).

To compile MariaDB, you need a set of core build tools and development headers for various libraries.

Setting up the MariaDB Source Repository

> **Note:**
>
> Setting up the MariaDB source repository is optional but recommended. If you want to build the MariaDB version that comes with your operating system, you can skip this subsection, though.

Adding the MariaDB Repository Tool into the workflow ensures that you are getting the dependencies specifically tailored for the version of MariaDB you want to build (for instance, 11.8), rather than whatever outdated version happens to be in your operating system's default upstream repository.

Using the MariaDB Repository Tool

While your operating system's default repositories contain many build tools, they may lack the specific library versions required for the latest MariaDB releases. Using the MariaDB Repository Tool ensures your environment is perfectly synced with the version you intend to build.

1. Configure the Repository

Use the MariaDB Repository Configuration Tool to generate the setup commands for your specific operating system and desired MariaDB version.

Example for Ubuntu 24.04 and MariaDB 11.8 (**don't copy this blindly** – the example uses the 11.8 release and a specific mirror; adjust these strings based on the output of the Repository Configuration Tool):

```
sudo apt-get install software-properties-common dirmngr
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
sudo add-apt-repository --update --yes --enable-source \
'deb [arch=amd64] https://mirrors.xtom.com/mariadb/repo/11.8/ubuntu noble main'
```

2. Install Tailored Dependencies

Once the repository is active and the `source` lines are enabled, you can use the package manager to pull exactly what that specific MariaDB version requires:

> **UBUNTU / DEBIAN**
>
> ```
> sudo apt-get build-dep mariadb-11.8  # Replace with your target version
> ```
>
> **RHEL / CENTOS / FEDORA**
>
> ```
> sudo dnf builddep mariadb-server
> ```

Advantages of Using the Repository Tool

1. Version Accuracy: If MariaDB 11.x requires a newer `libssl` or `zstd` than what your operating system provides by default, the MariaDB repo often provides the correct headers.
2. Completeness: It automatically handles the "Source Repositories" issue because the `add-apt-repository` command includes the `--enable-source` flag by default.
3. Automation: It reduces the "Manual Package Table" from a primary task to a fallback for users who cannot or will not add external repositories.

The "Shortcut" Command

Most Linux distributions allow you to install all necessary dependencies for the "official" build with a single command.

This requires that "source repositories" are enabled in your package manager. Enable them like this:

> **UBUNTU**
>
> Run this command:
>
> ```
> sudo add-apt-repository --update --yes --enable-source
> ```
>
> **DEBIAN**
>
> Edit `/etc/apt/sources.list` and uncomment lines starting with `deb-src`.
>
> **RHEL / ALMA**
>
> Run `dnf config-manager --set-enabled baseos-source appstream-source`.
>
> **FEDORA**
>
> Source repos are usually enabled by default, but check `dnf repolist` to verify.

The shortcut command itself varies by operating system:

> **UBUNTU / DEBIAN**
>
> `sudo apt build-dep mariadb-server`
>
> **RHEL / CENTOS / FEDORA**
>
> `sudo dnf builddep mariadb` (or `yum-builddep mariadb-server`)
>
> **SLES / OPENSUSE**
>
> `sudo zypper source-install -d mariadb`
>
> **MACOS**
>
> Homebrew does not have a direct `build-dep` command. You can install the standard MariaDB build stack using:
>
> ```
> brew install cmake git bison flex openssl zlib boost
> ```

Manual Package Table

If you are building a specific version or don't want to use the shortcut, use the list below to install the mandatory packages.

> **UBUNTU / DEBIAN**
>
> Use `apt` to install these tools:
>
> - Build tools: `build-essential git cmake`
> - Parser tools: `bison flex`
> - Terminal/UI: `libncurses-dev`
> - Security/SSL: `libssl-dev` or `gnutls-dev`
> - Compression: `zlib1g-dev`
> - Miscellaneous headers: `libaio-dev libboost-all-dev`
>
> **RHEL / CENTOS / FEDORA**
>
> Use `dnf` (or `yum`) to install these tools:
>
> - Build tools: `gcc-c++ git cmake`
> - Parser tools: `bison flex`
> - Terminal/UI: `ncurses-devel`
> - Security/SSL: `openssl-devel`
> - Compression: `zlib-devel`
> - Miscellaneous headers: `libaio-devel boost-devel`
>
> **SLES / OPENSUSE**
>
> Use `zypper` to install these tools:
>
> - Build tools: `gcc-c++ git cmake`
> - Parser tools: `bison flex`
> - Terminal/UI: `ncurses-devel`
> - Security/SSL: `libopenssl-devel`
> - Compression: `libzlib-devel`
> - Miscellaneous headers: `libaio-devel boost-devel`

> **MACOS**
>
> Use `brew` to install these tools:
>
> - Build tools: `cmake git`
> - Parser tools: `bison flex`
> - Terminal/UI: `ncurses`
> - Security/SSL: `openssl`
> - Compression: `zlib`
> - Miscellaneous headers: `boost`
>
> The system-provided version of `bison` on macOS is often too old. After running `brew install bison`, you may need to add it to your `PATH`:
>
> ```
> export PATH="/opt/homebrew/opt/bison/bin:$PATH"
> ```

Optional Dependencies (Plugins & Features)

If you plan to enable specific storage engines or features, install these additional packages:

Feature	Dependency	Package Name (Generic)
S3 Storage Engine	`libcurl`	`libcurl-devel` / `libcurl4-openssl-dev`
GSSAPI (Kerberos)	`krb5`	`krb5-devel` / `libkrb5-dev`
RocksDB / MyRocks	`snappy, lz4, zstd`	
Systemd Support	`systemd`	`systemd-devel` / `libsystemd-dev`
Authentication	`pam`	`pam-devel` / `libpam0g-dev`

Obtaining the Source Code

> This section covers the details of step 2 (Obtain the Source Code).

Depending on your goal, you can either clone the repository using Git or download a stable source tarball.

Option A: Git Clone (Recommended for Developers)

Using Git allows you to easily switch between versions and contribute patches. MariaDB uses submodules for certain components; you must initialize these for the build to succeed.

1. Clone the specific branch:

   Choose a branch that matches the major version you need (for instance, `11.8`).

   ```
   git clone --branch 11.8 https://github.com/MariaDB/server.git
   cd server
   ```

2. Initialize Submodules:

   This command downloads the source code for external storage engines and connectors.

   ```
   git submodule update --init --recursive
   ```

Option B: Source Tarball (Best for Stability)

If you do not need version control, downloading a pre-packaged source tarball is simpler. Submodules are already included in the tarball, so no extra steps are required.

1. Download: Visit the MariaDB Downloads page and select the “Source” tab.
2. Extract:

```
tar -xf mariadb-11.8.x.tar.gz
cd mariadb-11.8.x
```

Key Takeaway: Git vs. Tarball

Feature	Git Clone	Source Tarball
Updates	Easy (`git pull`)	Manual (download new version)
Submodules	Requires manual initialization	Pre-included
History	Full commit history available	No history included
Size	Larger (includes `.git` data)	Smaller

Common CMake Configuration Flags

> This section covers the details of step 3 (Configure the Build).

When running `cmake ..`, you can pass these options (using the `-D` prefix) to customize how MariaDB is built.

Category	Flag	Description
Install Path	`-DCMAKE_INSTALL_PREFIX=/opt/mariadb`	Defines where the server is installed (default: `/usr/local`).
Build Type	`-DCMAKE_BUILD_TYPE=RelWithDebInfo`	Options: `Release` , `Debug` , `RelWithDebInfo` (recommended).
Features	`-DWITH_EMBEDDED_SERVER=ON`	Builds the `libmariadbd` embedded library.
Storage Engines	`-DPLUGIN_ROCKSDB=NO`	Explicitly disables a specific storage engine (use `YES` to force enable).
Security	`-DWITH_SSL=system`	Use the system’s OpenSSL (default). Options: `system` , `openssl` , `gnutls` .
Debugging	`-DWITH_ASAN=ON`	Enables AddressSanitizer to find memory leaks.
Standardization	`-DBUILD_CONFIG=mysql_release`	Configures the build to match the official MariaDB release binaries.

Pro-Tip: Managing Plugins

Most plugins are auto-detected based on the dependencies you installed in step 1. To see a full list of available options and their current status, run:

```
cmake .. -LH
```

The Quick Way: Using BUILD Scripts

> This section covers alternative details of step 3 (Configure the Build).

If you don’t want to manually toggle CMake flags, MariaDB includes a `BUILD/` directory containing pre-configured scripts for common development environments. These are especially useful for developers who need a specific setup (like a Debug build with Valgrind support) quickly.

How to Use a BUILD Script

These scripts must be run from the root of the source directory (unlike the manual “out-of-source” CMake method).

```
# Example: Build an optimized 64-bit version with debugging symbols
./BUILD/compile-pentium64-debug
```

Common Script Variants

Most scripts follow a naming convention: `compile-[architecture]-[type]`.

Script	Best For…
`compile-pentium64-debug`	Standard 64-bit development with debug symbols.
`compile-pentium64-max`	Enables almost all features and plugins (highest compatibility).
`compile-pentium64-valgrind-max`	Optimized for memory testing with Valgrind.
`compile-amd64-debian-build`	Mimics the configuration used for official Debian/Ubuntu packages.

Adding Extra Flags

You can still pass custom CMake flags to these scripts using environment variables or arguments, though most users find the defaults sufficient for testing.

```
./BUILD/compile-pentium64-debug --extra-configs="-DCMAKE_INSTALL_PREFIX=/tmp/mariadb"
```

Troubleshooting Common Build Errors

> This section covers details of step 4 (Compile).

Compiling from source often hits roadblocks. Here are the most common issues and how to fix them.

Error Message	Likely Cause	Solution
`CMAKE_CXX_COMPILER not found`	Missing C++ compiler.	Install `g++` (Linux) or `clang` (macOS).
`Bison version is too old`	macOS default `bison` is outdated.	`brew install bison` and update your `PATH`.
`Could not find GSSAPI`	Missing Kerberos headers.	Install `libkrb5-dev` or `krb5-devel`.
`Could not find Curses`	Missing terminal headers.	Install `libncurses-dev` or `ncurses-devel`.
`No space left on device`	`/tmp` or build dir is full.	MariaDB requires ~5GB to 10GB of disk space for a full build.

The “Clean Slate” Command

If you changed your CMake flags and things are getting weird, the best fix is to wipe the cache and start over.

```
# Inside your build directory
rm -rf *
cmake .. [your flags]
```

> **Note:**
>
> Do not delete the source directory, only the contents of the `build` folder.

Notes

Conventional Data Directory Locations

This table lists typical locations of `--datadir`.

Platform	Conventional Data Directory
Linux (General)	`/var/lib/mysql`
macOS (Homebrew)	`/opt/homebrew/var/mysql`
macOS (Intel/Legacy)	`/usr/local/var/mysql`
FreeBSD	`/var/db/mysql`
Custom/Dev Build	`~/mariadb-data` (or any folder owned by your user)

Post-Build

> This section covers optional additional things to do after building MariaDB successfully (step 8 (After Building)).

Packaging

If you need to deploy MariaDB to multiple servers, you don't have to compile it on every machine. Instead, use MariaDB's built-in packaging support to create a distributable package.

MariaDB uses CPack (part of the CMake suite) to generate these packages.

1. Configure for Packaging: To ensure the package follows standard filesystem hierarchies, use the `mysql_release` configuration.

   ```
   cmake .. -DBUILD_CONFIG=mysql_release
   ```

2. Generate the Package: After the build is complete, run `cpack` from your build directory.

   ```
   # To create the default package for your OS (DEB on Ubuntu/Debian, RPM on RHEL)
   cpack -G DEB   # For Debian-based
   cpack -G RPM   # For RedHat-based
   cpack -G TGZ   # For a generic binary tarball
   ```

3. Result: You will find a file like `mariadb-11.x.x-linux-x86_64.deb` in your build directory, which can be installed via `dpkg -i` or `rpm -ivh`.

Building MariaDB on Windows

Build Requirements

To build MariaDB you need the following:

- Visual C++: We currently support Visual Studio 2019 and 2022. Generally we try to support the two most recent VS versions, but build ourselves using the last one. Community editions will work fine; we only use them in our builds.
  While installing Visual Studio, make sure to add “Desktop Development with C++”.
  Also, make sure to use recent enough Windows SDK - latest Windows 11 SDK is recommended.
- CMake: We recommend the latest release. Older releases might not support your version of Visual Studio. Visual Studio 2019 requires cmake 3.14 at least.
- Git: Required to build newer versions from the source tree.
  - NOTE: run

```
git config --global core.autocrlf input
```

after the installation, otherwise some mtr tests will fail

In the “Adjusting your PATH” dialog, choose “Use Git from Windows command prompt”, otherwise wrong (mingw64) git and perl will be in your PATH

- Bison from GnuWin32:
  Bison creates parts of the SQL parser. Choose “Complete package except sources” when downloading.
  - NOTE: Do not install this into your default path with spaces (e.g. under `C:\Program Files\GnuWin32`); the build will break due to this bison bug.
    Instead, install into `C:\GnuWin32`.
  - Add `C:\GnuWin32\bin` to your system `PATH` after installation.
- Strawberry perl: Used to run the test suite.ActiveState Perl is another Win32 Perl distribution and should work as well (but it is not as well tested). NOTE: `Cygwin` or `mingw` Perl versions will not work for testing. Use Windows native Perl, please.
- Optional: If you intend to build the MSI packages, install Windows Installer XML . If you build MSI with 10.4, also modify your Visual Studio installation, add “Redistributable MSMs” (see MDEV-22555)
- Gnu Diff, needed if you run mysql-test-run.pl tests.

Verify that bison.exe, or git.exe, cmake.exe and perl.exe can be found in the PATH environment variable with “`where bison`”, “`where git`”, “`where perl`” etc. from the command line prompt.

Building Windows Binaries

The above instructions assume MariaDB 10.2 or higher.

Branch the MariaDB repository, or unpack the source archive. On the command prompt, switch to your source directory, then execute:

```
mkdir bld
cd bld
cmake ..
cmake --build . --config RelWithDebInfo
```

The above example builds a release configured for 64 bit systems in a subdirectory named `bld`. “`cmake ..`” is the configuration step,
“`cmake --build . --config Relwithdebinfo`” is the build step.

Build Variations

Debug Builds

Building Debug version is done with:

```
cmake --build . --config Debug
```

32bit and 64 bit Builds

Build 64 bit binary

Visual Studio 2019-2022 `cmake` generator will use host architecture by default, that is, with the steps above, `cmake` will build x64 binaries on x64 machine.

Build 32 bit binary

pass `-A Win32` parameter for `cMake`, like this

```
cmake .. -A Win32
```

Historical note:
With Visual Studio 2017 and earlier, one had to pass the name of 32bit generator ,e.g `cmake .. -G "Visual Studio 15 2017`

For a complete list of available generators, call `cmake` without any parameters.

IDE Builds

Instead of calling "`cmake --build`" as above, open solution file `MariaDB.sln` (in older versions, prior to 11.0, `MySQL.sln`). When Visual Studio starts, choose Build/Compile.

Building the ZIP Package

```
cmake --build . --config relwithdebinfo --target package
```

This is how it is "done by the book", standard `cmake` target.

MariaDB however uses non-standard target `win_package` for the packaging for its releases, it generates 2 ZIPs, a slim one with executables, and another one with `debuginfo` (.PDB files). The `debuginfo` is important to be able to debug released binaries, and to analyze crashes.

```
cmake --build . --config relwithdebinfo --target win_package
```

Building the MSI Package

```
cmake --build . --config relwithdebinfo
cmake --build . --config relwithdebinfo --target MSI
```

Including HeidiSQL in the MSI Installer

Starting with MariaDB 5.2.7, it is possible to build an installer which includes 3rd party products, as described in MWL#200. Currently only HeidiSQL support is implemented; it is also included in the official builds. Use the `CMake` parameter `-DWITH_THIRD_PARTY=HeidiSQL` to include it in the installer.

Code Signing

MariaDB builds optionally support authenticode code signing with an optional parameter `SIGNCODE`. Use `cmake -DSIGNCODE=1` during the configuration step to sign the binaries in the `ZIP` and `MSI` packages.

Important: for `SIGNCODE=1` to work, the user that runs the build needs to install a valid authenticode digital certificate into their certificate store, otherwise the packaging step will fail.

Building Packages for MariaDB Releases

The full script to create the release in an out-of-source build with Visual Studio with signed binaries might look like:

```
mkdir bld
cd bld
cmake .. -DSIGNCODE=1 -DWITH_THIRD_PARTY=HeidiSQL
cmake --build . --config relwithdebinfo --target win_package
cmake --build . --config relwithdebinfo  --target MSI
```

This command sequence will produce a ZIP package (e.g mariadb-5.2.6-win32.zip) and MSI package (e.g mariadb-5.2.6-win32.msi) in the `bld` directory.

Running Tests

- Important: Do not use Cygwin bash, MinGW bash, Git bash, WSL bash, or any other bash when running the test suite. You will then very likely use the wrong version of Perl too (a “Unix-flavoured” one on Windows), and spend a lot of time trying to figure out why this version of Perl does not work for the test suite. Use native perl, in cmd.exe , or powershell instead,
- Switch `mysql-test` subdirectory of the build directory

```
cd C:\server\bld\mysql-test
```

- Run the test suite

```
perl mysql-test-run.pl --suite=main --parallel=auto
```

Running a Test Under Debugger

Assuming VS is installed on the machine

```
perl mysql-test-run.pl  <test_name> --vsjitdebugger
```

If `vsjitdebugger` does not start, you can edit `AeDebug` registry key as mentioned in

debug-using-the-just-in-time-debugger?view=vs-2019#jit_errors

Alternatively:

```
perl mysql-test-run.pl  <test_name> --devenv
```

(devenv.exe needs to be in PATH)

or, if you prefer `WinDBG`

```
perl mysql-test-run.pl  <test_name> --windbg
```

Cross-compiling MariaDB

Buildroot

Buildroot is a way to cross compile MariaDB and other packages into a root filesystem. In the menuconfig you need to enable “Enable C++ Support” first under “Toolchain”. After C++ is enabled MariaDB is an option under “Target Packages” ->“Libraries” -> “Databases” -> “mysql support” -> “mysql variant” -> “mariadb”. Also enable the “mariadb server” below the “mysql support” option.

Details

To cross-compile with `cmake` you will need a `toolchain` file. See, for example, here. Besides `cmake` specific variables it should have, at least

```
SET(STACK_DIRECTION -1)
  SET(HAVE_IB_GCC_ATOMIC_BUILTINS 1)
```

with appropriate values for your target architecture. Normally these MariaDB configuration settings are detected by running a small test program, and it cannot be done when cross-compiling.

Note that during the build few helper tools are compiled and then immediately used to generate more source files for this very build. When cross-compiling these tools naturally should be built for the host architecture, not for the target architecture. Do it like this (assuming you’re in the mariadb source tree):

```
$ mkdir host
$ cd host
$ cmake ..
$ make import_executables
$ cd ..
```

Now the helpers are built and you can cross-compile:

```
$ mkdir target
$ cd target
$ cmake .. -DCMAKE_TOOLCHAIN_FILE=/path/to/toolchain/file.cmake -
DIMPORT_EXECUTABLES=../host/import_executables.cmake
$ make
```

Here you invoke `cmake` , specifying the path to your toolchain file and the path to the `import_executables.cmake` that you have just built on the previous step. Of course, you can also specify any other cmake parameters that could be necessary for this build, for example, enable or disable specific storage engines.

Compiling MariaDB with Extra Modules/Options

See Specifying Which Plugins to Build.

Explains how to use CMake options like `PLUGIN_xxx` to control which plugins are built statically, dynamically, or not at all during compilation.

See Using MariaDB with TCMalloc or jemalloc.

Instructions on building and configuring MariaDB to use alternative memory allocators like TCMalloc or jemalloc for improved performance and profiling.

This page is licensed: CC BY-SA / Gnu FDL

Specifying Which Plugins to Build

By default all plugins are enabled and built as dynamic `.so` (or `.dll`) modules. If a plugin does not support dynamic builds, it is not built at all.

Use `PLUGIN_xxx` cmake variables. They can be set on the command line with `-DPLUGIN_xxx=value` or in the cmake gui. Supported values are

Value	Effect
`NO`	the plugin will be not compiled at all
`STATIC`	the plugin will be compiled statically, if supported. Otherwise it will be not compiled.
`DYNAMIC`	the plugin will be compiled dynamically, if supported. Otherwise it will be not compiled. This is the default behavior.
`AUTO`	the plugin will be compiled statically, if supported. Otherwise it will be compiled dynamically.
`YES`	same as AUTO, but if plugin prerequisites (for example, specific libraries) are missing, it will not be skipped, it will abort cmake with an error.

Note that unlike autotools, cmake tries to configure and build incrementally. You can modify one configuration option and cmake will only rebuild the part of the tree affected by it. For example, when you do `cmake -DWITH_EMBEDDED_SERVER=1` in the already-built tree, it will make libmysqld to be built, but no other configuration options will be changed or reset to their default values.

In particular this means that if you have run, for example `cmake -DPLUGIN_OQGRAPH=NO` and later you want to restore the default behavior (with OQGraph being built) in the same build tree, you would need to run `cmake -DPLUGIN_OQGRAPH=DYNAMIC`

Alternatively, you might simply delete the `CMakeCache.txt` file — this is the file where cmake stores current build configuration — and rebuild everything from scratch.

Using MariaDB with TCMalloc or jemalloc

> **Note:**
>
> Read the Profiling Memory Usage page for more information on how to debug high memory consumption.

Using tcmalloc or jemalloc

TCMalloc is a malloc replacement library optimized for multi-threaded usage. It features a built-in heap debugger and profiler. Another malloc replacement that can speed up MariaDB is jemalloc.

The procedures to use one of these libraries with MariaDB are the same. Many other malloc replacement libraries (as well as heap debuggers and profilers) can be used with MariaDB in a similar fashion.

Prerequisites

`jemalloc` is a powerhouse for reducing memory fragmentation and improving concurrency, but it isn't a "one-size-fits-all" drop-in for every environment. Its availability and stability depend heavily on how the operating system handles memory pages and how MariaDB was compiled.

Operating System Availability

- Linux: Jemalloc is most at home here. Most major distributions (Ubuntu, Debian, CentOS/RHEL, Arch) include it in their official repositories (`libjemalloc2` or `jemalloc`). It is the standard recommendation for high-traffic MariaDB setups on Linux.

- Windows: Jemalloc does not have the same “native” presence on Windows. While the `jemalloc` source code can technically be compiled for Windows using MSVC or MinGW, MariaDB for Windows is almost exclusively used with the default Windows system allocator. Most DBAs do not use `jemalloc` on Windows production servers.
- FreeBSD: This is the “birthplace” of `jemalloc` – it replaced the system malloc in FreeBSD back in 2005. If you are running MariaDB on FreeBSD, you are likely using `jemalloc` by default at the OS level.

Hardware and Architecture Hurdles

One of the most common “hidden” failures occurs on non-x86 architectures:

- Raspberry Pi (ARM): On newer devices like the Raspberry Pi 5, `jemalloc` often fails to start with the error: `<jemalloc>: Unsupported system page size`. This happens because `jemalloc` is frequently compiled assuming a 4KB page size, while many ARM kernels now use 16KB or 64KB pages for better performance.
- Cloud Instances: Small instances (like AWS `t2.micro`) can sometimes behave unpredictably with `jemalloc` if they lack sufficient swap space or if the memory overhead of the `jemalloc` metadata conflicts with the tiny RAM footprint.

Compatibility Matrix Summary

Platform	Jemalloc Support	Typical Usage
Linux (x86_64)	Excellent	Highly recommended; installed via `apt` or `yum`.
FreeBSD	Native	It is the system default.
Windows	Poor/Partial	Rarely used; usually requires custom builds.
ARM (RPi/M1/M2)	Conditional	Depends on the kernel page size (4KB vs 16KB).
Solaris/Illumos	Experimental	Possible but lacks the robust testing seen on Linux.

Check if it’s Ready to Use

Before trying to force it via `LD_PRELOAD`, check if the library even exists on your system paths:

```
# On Debian/Ubuntu
find /usr/lib -name "libjemalloc.so.*"

# On RHEL/CentOS
find /usr/lib64 -name "libjemalloc.so.*"
```

If these commands return nothing, you need to install the package first (`sudo apt install libjemalloc2` or `sudo dnf install jemalloc`).

Why Use it

The main reason to switch isn’t just speed, but fragmentation. Standard `malloc` can leave small gaps of unused memory that the OS can’t reclaim, leading to “memory bloat” where MariaDB appears to use 10GB of RAM even if the data only needs 6GB. Jemalloc is much better at packing these allocations tightly.

Checking the malloc Implementation in Use

To check which `malloc` implementation is used, run this query:

```
SHOW GLOBAL VARIABLES LIKE 'version_malloc_library';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| version_malloc_library | system |
+-------------------------+--------+
```

A value of `system` indicates the system default, which is normally `malloc`. If another library is used, the name and version of the library is shown.

Building MariaDB With an Alternative to malloc

To build MariaDB with `TCMalloc`, you need to use the following command:

```
cmake -DCMAKE_EXE_LINKER_FLAGS='-ltcmalloc'  -DWITH_SAFEMALLOC=OFF
```

To use `jemalloc`, specify `-ljemalloc` instead of `-ltcmalloc`.

Starting mariadbd-safe With an Alternative to malloc

Start a standard MariaDB server with `TCmalloc` like this:

```
/usr/sbin/mariadbd-safe --malloc-lib=tcmalloc
```

To configure mariadbd-safe to use `tcmalloc` or `jemalloc`, add this to your configuration file:

```
[mariadbd-safe]
malloc-lib=tcmalloc
```

Starting mariadbd With an Alternative to malloc

Locate the library file that needs to be used:

```
# jemalloc
find /usr/lib -name "libjemalloc.so.*"
# tcmalloc
find /usr/lib -name "libtcmalloc.so.*"
```

Pass that library file to `mariadbd` using the `LD_PRELOAD` variable:

```
LD_PRELOAD=/path/to/library mariadbd
```

Configuring systemd

If you use `systemd` to run MariaDB, locate the library as explained above, then locate the service configuration file:

```
systemctl status mariadb | grep Loaded
```

Edit the `mariadb.service` file by adding a line to the `[Service]` group:

```
[Service]
Environment=LD_PRELOAD=<path-to-library>
```

For example, add this:

```
[Service]
Environment=LD_PRELOAD=/usr/lib/x86_64-linux-gnu/libjemalloc.so.2
```

Reload the configuration for the news setting to take effect, and restart MariaDB:

```
systemctl daemon-reload
systemctl restart mariadb
```

Dockerfile

If you run MariaDB on Docker and use an image from a Dockerfile that is publicly available, most probably you have an entry point that is a bash script, which starts `mariadbd` directly. Edit that bash script, or set the `LD_PRELOAD` variable from the Dockerfile:

```
ENV LD_PRELOAD=<path-to-library>
```

To find the library file, run one of these commands while the container is running:

```
# jemalloc
docker exec -ti <container-name> find /usr/lib -name "libjemalloc.so.*"
# tcmalloc
docker exec -ti <container-name> find /usr/lib -name "libtcmalloc.so.*"
```

Example:

```
docker run -P -d --name mariadb --env LD_PRELOAD="/usr/lib/x86_64-linux-gnu/libjemalloc.so.2" --env
MARIADB_ROOT_PASSWORD=Password123! mariadb:latest
```

Vagrantfile

Usually Vagrant is used to start a complete system in a virtual machine. In that case, you can use one of the methods above, for example you can modify your Vagrantfile to copy a modified version of the `mariadb.service` file to the guest system to configure systemd.

If you use Vagrant with the Docker provider, you can follow the instructions above to modify the Dockerfile.

Making jemalloc Persistent

To make MariaDB use `jemalloc` persistently, set it up like this. These instructions work on Linux using `systemd` and running on an x86 architecture.

Steps

Step 1

Identify the jemalloc library path.

Identify the `jemalloc` library path, to find the exact location of the `jemalloc` shared library on your system:

```
find /usr -name "libjemalloc.so.*"
```

Take a note of the output path. Typically, it is something like `/usr/lib64/libjemalloc.so.2`.

Step 2

Create or edit the MariaDB Systemd override file.

This is the crucial step for persistence. Use `systemctl edit` to manage the override file:

```
sudo systemctl edit mariadb
```

If an override file already exists for MariaDB, it opens in the editor. If not, the editor creates a new, empty file, typically at `/etc/systemd/system/mariadb.service.d/override.conf`. Add the following content to the file:

```
[Service]
Environment="LD_PRELOAD=/usr/lib64/libjemalloc.so.2"
```

Replace `/usr/lib64/libjemalloc.so.2` with the actual path you noted in step 1. Save the file and exit the editor.

Step 3

Restart services and MariaDB.

```
sudo systemctl daemon-reexec
sudo systemctl daemon-reload
sudo systemctl restart mariadb
```

Step 4

Reboot the computer, and verify that jemalloc is used.

You can verify this on various levels.

MariaDB:

```
mariadb -e "SHOW GLOBAL VARIABLES LIKE 'version_malloc_library';"
+------------------------+----------------------------------------------------------+
| Variable_name          | Value                                                    |
+------------------------+----------------------------------------------------------+
| version_malloc_library | jemalloc 5.2.1-0-gea6b3e973b477b8061e0076bb257dbd7f3faa756 |
+------------------------+----------------------------------------------------------+
```

Operating system:

```
sudo cat /proc/$MARIADB_PID/environ | tr '\0' '\n' | grep LD_PRELOAD
LD_PRELOAD=/usr/lib64/libjemalloc.so.2
```

Operating system processes:

```
sudo cat /proc/$MARIADB_PID/maps | grep jemalloc
7f6981c00000-7f6981c06000 r--p 00000000 fd:00 50981369 /usr/lib64/libjemalloc.so.2
7f6981c06000-7f6981c76000 r-xp 00006000 fd:00 50981369 /usr/lib64/libjemalloc.so.2
7f6981c76000-7f6981c81000 r--p 00076000 fd:00 50981369 /usr/lib64/libjemalloc.so.2
7f6981c81000-7f6981c87000 r--p 00080000 fd:00 50981369 /usr/lib64/libjemalloc.so.2
7f6981c87000-7f6981c88000 rw-p 00086000 fd:00 50981369 /usr/lib64/libjemalloc.so.2
```

Notes

`systemctl edit` creates a separate configuration file (`/etc/systemd/system/mariadb.service.d/override.conf`). `systemd` always prioritizes settings in override files over the main service file (`/usr/lib/systemd/system/mariadb.service`).

When upgrading MariaDB, the package manager only replaces or updates the main service file. Your custom override file in `/etc/systemd/system/mariadb.service.d/` remains untouched, thus preserving your `jemalloc`

configuration.

`systemd` reads all its service configurations, including override files, on system start. This means the `LD_PRELOAD` environment variable is set for MariaDB automatically each time the service starts, making the change persistent across reboots.

Finding memory leaks with jemalloc

`jemalloc` provides a report of memory leaks at program exit:

```
MALLOC_CONF=prof_leak:true,lg_prof_sample:0,prof_final:true \
LD_PRELOAD=${JEMALLOC_PATH}/lib/libjemalloc.so.2  path-to-mariadbd
```

This produces output like this:

```
<jemalloc>: Leak summary: 267184 bytes, 473 objects, 20 contexts
<jemalloc>: Run jeprof on "jeprof.19678.0.f.heap" for leak detail
```

You can learn more about the memory leaks with `jeprof`, which is shipped with jemalloc:

```
jeprof --show_bytes path-to-mariadbd jeprof.19678.0.f.heap
```

You can also generate a PDF call graph of the leak:

```
jeprof --show_bytes --pdf path-to-mariadbd  jeprof.19678.0.f.heap > /tmp/mariadbd.pdf
```

Configuring MariaDB with Option Files

You can configure MariaDB to run the way you want by configuring the server with MariaDB's option files. The default MariaDB option file is called `my.cnf` on Unix-like operating systems and `my.ini` on Windows. Depending on how you've installed MariaDB, the default option file may be in a number of places, or it may not exist at all.

MariaDB Enterprise Server users should also refer to the Enterprise Server-Specific section for additional configuration files like `mariadb-enterprise.cnf`.

Global Options Related to Option Files

The following options relate to how MariaDB handles option files. These options can be used with most of MariaDB's command-line tools, not just mariadbd. They must be given as the first argument on the command-line:

Option	Description
–print-defaults	Read options from option files, print all option values, and then exit the program.
–no-defaults	Don't read options from any option file.
–defaults-file =path	Only read options from the given option file.
–defaults-extra-file =path	Read this extra option file after all other option files are read.
–defaults-group-suffix =suffix	In addition to the default option groups, also read option groups with the given suffix.

Default Option File Locations

MariaDB reads option files from many different directories by default. See the sections below to find out which directories are checked for which system.

For an exact list of option files read on your system by a specific program, you can execute a command like this (`$program` stands for any MariaDB program, including the Server):

```
$program --help --verbose
```

For example:

```
$ mariadbd --help --verbose
mariadbd  Ver 10.11.2-MariaDB for linux-systemd on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mariadbd [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.11 mariadb mariadb-10.11 mariadbd mariadbd-10.11
client-server galera
....
```

The option files are each scanned once, in the order given by `--help --verbose`. The effect of the configuration options is the same as if they would have been given as command-line options in the order they are found.

Default Option File Locations on Linux and Unix

On Linux and Unix operating systems, the default option file is called `my.cnf`. MariaDB looks for the MariaDB option file in the locations and orders listed below.

The locations are dependent on whether the `DEFAULT_SYSCONFDIR` cmake option was defined when MariaDB was built. This option is usually defined as `/etc` when building RPM packages, but it is usually not defined when building DEB packages or binary tarballs.

- If the `DEFAULT_SYSCONFDIR` `cmake` option is **undefined**, MariaDB looks for the MariaDB option file in the following locations, and in the following order:

Location	Scope
`/etc/my.cnf`	Global
`/etc/mysql/my.cnf`	Global
`$MARIADB_HOME/my.cnf`	Server (from MariaDB 10.6)

Location	Scope
`$MYSQL_HOME/my.cnf`	Server (before MariaDB 10.6)
`defaults-extra-file`	File specified with –defaults-extra-file, if any
`~/.my.cnf`	User

- If the `DEFAULT_SYSCONFDIR` `cmake` option is **defined**, MariaDB looks for the MariaDB option file in the following locations in the following order:

Location	Scope
`DEFAULT_SYSCONFDIR/my.cnf`	Global
`$MARIADB_HOME/my.cnf`	Server (from MariaDB 10.6)
`$MYSQL_HOME/my.cnf`	Server (before MariaDB 10.6)
`defaults-extra-file`	File specified with –defaults-extra-file, if any
`~/.my.cnf`	User

- `MARIADB_HOME` or `MYSQL_HOME` is the environment variable containing the path to the directory holding the server-specific `my.cnf` file. If `MYSQL_HOME` is not set, and the server is started with mysqld_safe, `MYSQL_HOME` is set as follows:
  - If there is a `my.cnf` file in the MariaDB data directory, but not in the MariaDB base directory, `MYSQL_HOME` is set to the MariaDB data directory.
  - Else, `MYSQL_HOME` is set to the MariaDB base directory.

> **Warning:**
>
> Note that if `MARIADB_HOME` is set, `MYSQL_HOME` is not used, even if set.

Default Option File Locations on Windows

On Windows, the option file can be called either `my.ini` or `my.cnf`. Depending on the distribution, MariaDB Enterprise Server for Windows may include additional configuration files. These files comply with the load order rules described in the following section.

MariaDB looks for option files in the following locations, and in the following order:

Location	Scope
System Windows Directory\my.ini	Global
System Windows Directory\my.cnf	Global
Windows Directory\my.ini	Global
Windows Directory\my.cnf	Global
`c:\my.ini`	Global
`c:\my.cnf`	Global
`installdir\my.ini`	Server
`installdir\my.cnf`	Server
`installdir\data\my.ini`	Server
`installdir\data\my.cnf`	Server
`%mariadb_home%\my.ini`	Server (from MariaDB 10.6)
`%mariadb_home%\my.cnf`	Server (from MariaDB 10.6)

Location	Scope
`%mysql_home%\my.ini`	Server
`%mysql_home%\my.cnf`	Server
`defaults-extra-file`	File specified with –defaults-extra-file, if any

- The `System Windows Directory` is the directory returned by the GetSystemWindowsDirectory function. The value is usually `C:\Windows`. To find its specific value on your system, open cmd.exe and execute:

```
echo %WINDIR%
```

- The `Windows Directory` is the directory returned by the `GetWindowsDirectory` function. The value may be a private `Windows Directory` for the application, or it may be the same as the `System Windows Directory` returned by the `GetSystemWindowsDirectory` function.
- `INSTALLDIR` is the parent directory of the directory where `mysqld.exe` is located. For example, if `mysqld.exe` is in `C:\Program Files\` , `INSTALLDIR` is `C:\Program Files\`.
- `MARIADB_HOME` or `MYSQL_HOME` is the environment variable containing the path to the directory holding the server-specific `my.cnf` file.

> **Warning:**
>
> Note that if `MARIADB_HOME` is set, `MYSQL_HOME` is not used, even if set.

MariaDB Enterprise Server Option File Locations

MariaDB Enterprise Server includes additional configuration files that are installed with the Enterprise Server packages. Specifically, the file `mariadb-enterprise.cnf` is typically placed in a configuration include directory and enables Enterprise-specific features by default (for example, loading the Enterprise Audit plugins with `plugin-load-add`, `server_audit` and other enterprise plugins):

```
/etc/my.cnf.d/mariadb-enterprise.cnf
```

The configuration values defined in these files can be validated at runtime. See Verifying Option File Sources in Enterprise Server.

Default Option File Hierarchy

MariaDB looks in all of the above locations, in order, even if it has already found an option file, and it's possible for more than one option file to exist. For example, you could have an option file in `/etc/my.cnf` with global settings for all servers, and another option file in `~/.my.cnf` (that is, your user account's home directory) which specifies additional settings (or override previously specified settings) that are specific only to that user.

Option files are usually optional. However, if the –defaults-file option is set, but the file does not exist, MariaDB raises an error. If the `--defaults-file` option is set, MariaDB *only* reads the option file referred to by this option.

If an option or system variable is not explicitly set, then it will be set to its default value. See Server System Variables for a full list of all server system variables and their default values.

> **Warning:**
>
> If an option is set multiple times, the later setting will override the earlier setting.

If –log-basename is set, there are various other log file naming options that, if set, should be placed **later** in the configuration file hierarchy. Later settings override earlier settings, so `log-basename` overrides any earlier log file name settings. See –log-basename for details.

Custom Option File Locations

MariaDB can be configured to read options from custom options files with the following command-line arguments. These command-line arguments can be used with most of MariaDB's command-line tools, not just mariadbd. They must be given as the first argument on the command line:

Option	Description
–defaults-file =path	Only read options from the given option file.
–defaults-extra-file =path	Read this extra option file after all other option files are read.

Option File Syntax

The syntax of MariaDB option files is as follows:

- Lines starting with `#` are comments.
- Empty lines are ignored.
- Option groups use the syntax `[group-name]`. See the Option Groups section below for more information on available option groups.
- The same option group can appear multiple times.
- The `!include` directive can be used to include other option files. See the Including Option Files section below for more information on this syntax.
- The `!includedir` directive can be used to include all `.cnf` files (and potentially `.ini` files) in a given directory. The option files within the directory are read in alphabetical order. See the Including Option File Directories section below for more information on this syntax.
- The `?includedir` (introduced in MariaDB 11.4.10 and 11.8.6) directive works like `!includedir` but skips unreadable files, instead of failing with an error.
- Dashes (`-`) and underscores (`_`) in options are interchangeable.
- Double quotes can be used to quote values
- `\n`, `\r`, `\t`, `\b`, `\s`, `\"`, `\'`, and `\\` are recognized as character escapes for new line, carriage return, tab, backspace, space, double quote, single quote, and backslash respectively.
- Certain option prefixes are supported. See the Option Prefixes section below for information about available option prefixes.
- See the Options section below for information about available options.

Option Groups

A MariaDB program can read options from one or many option groups. For an exact list of option groups read on your system by a specific program, you can execute (`$program` is a placeholder for any MariaDB program):

```
$program --help --verbose
```

For example:

```
$ mariadbd --help --verbose
mariadbd  Ver 10.11.2-MariaDB for linux-systemd on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mariadbd [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.11 mariadb mariadb-10.11 mariadbd mariadbd-10.11
client-server galera
....
```

Server Option Groups

MariaDB programs reads server options from the following server option groups:

Group	Description
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[server]	Options read by MariaDB Server.
[mysqld]	Options read by mysqld, including both MariaDB Server and MySQL Server.
[mysqld-X.Y]	Options read by a specific version of mysqld, including both MariaDB Server and MySQL Server. For example, `[mariadb-11.4]`.
[mariadb]	Options read by MariaDB Server.
[mariadb-X.Y]	Options read by a specific version of MariaDB Server. For example, `[mariadb-11.4]`.
[mariadbd]	Options read by MariaDB Server.
[mariadbd-X.Y]	Options read by a specific version of MariaDB Server. For example, `[mariadbd-11.4]`.
[galera]	Options read by MariaDB Server, but only if it is compiled with Galera Cluster support. All builds on Linux are compiled with Galera Cluster support. When using one of these builds, options from this option group are read even if the Galera Cluster functionality is not enabled.

X.Y in the examples above refer to the base (major.minor) version of the server. For example, MariaDB 11.4 would read from `[mariadb-11.4]`. By using the `mariadb-X.Y` syntax, you can create option files that have MariaDB-only options in the MariaDB-specific option groups. That would allow the option file to work for both MariaDB and MySQL.

Client Option Groups

MariaDB programs reads client options from the following option groups:

Group	Description
[client]	Options read by all MariaDB and MySQL client programs, including both MariaDB and MySQL clients. For example, mariadb-dump.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[client-mariadb]	Options read by all MariaDB client programs.

Tool-Specific Option Groups

Many MariaDB tools reads options from their own option groups as well:

Group	Description
[mysqld_safe]	Options read by mysqld_safe, including both MariaDB Server and MySQL Server.
[safe_mysqld]	Options read by mysqld_safe, including both MariaDB Server and MySQL Server.
[mariadbd-safe]	Options read by mysqld_safe from MariaDB Server.
[mariadb_safe]	Options read by mysqld_safe from MariaDB Server. Deprecated, please avoid using this.
[mariadb-backup]	Options read by mariadb-backup.
[xtrabackup]	Options read by mariadb-backup and Percona XtraBackup.
[mysql_upgrade]	Options read by mysql_upgrade, including both MariaDB Server and MySQL Server.
[mariadb-upgrade]	Options read by mariadb-upgrade.
[sst]	Specific options read by the mariadb-backup SST method and the xtrabackup-v2 SST method.
[mysql]	Options read by mysql, including both MariaDB Server and MySQL Server.
[mariadb-client]	Options read by mariadb.
[mysqldump]	Options read by mysqldump, including both MariaDB Server and MySQL Server.
[mariadb-dump]	Options read by mariadb-dump.
[mysqlimport]	Options read by mysqlimport, including both MariaDB Server and MySQL Server.
[mariadb-import]	Options read by mariadb-import.
[mysqlbinlog]	Options read by mysqlbinlog, including both MariaDB Server and MySQL Server.
[mariadb-binlog]	Options read by mariadb-binlog.
[mysqladmin]	Options read by mysqladmin, including both MariaDB Server and MySQL Server.
[mariadb-admin]	Options read by mariadb-admin.
[mysqlshow]	Options read by mysqlshow, including both MariaDB Server and MySQL Server.
[mariadb-show]	Options read by mariadb-show. Note that this program reads `[client]` group options, too.
[mysqlcheck]	Options read by mariadb-check, including both MariaDB Server and MySQL Server.
[mariadb-check]	Options read by mariadb-check.
[mysqlslap]	Options read by mysqlslap, including both MariaDB Server and MySQL Server.
[mariadb-slap]	Options read by mariadb-slap.
[odbc]	Options read by MariaDB Connector/ODBC, but only if the USE_MYCNF parameter is set.

Custom Option Group Suffixes

MariaDB can be configured to read options from option groups with a custom suffix by providing the following command-line argument. This command-line argument can be used with most of MariaDB's command-line tools, not just mariadbd. It must be given as the first argument on the command line:

Option	Description
–defaults-group-suffix =suffix	In addition to the default option groups, also read option groups with the given suffix.

The default group suffix can also be specified via the `MYSQL_GROUP_SUFFIX` environment variable.

Example: To create a custom prompt for the `mariadb` command-line client via a custom group, add this to the option file (for instance, `/etc/my.cnf`):

```
[client_custom_group]
prompt='(custom prompt for mariadb client)'
```

Then, launch `mariadb` like this:

```
mariadb --defaults-group-suffix=_custom_group
```

Including Option Files

It is possible to include additional option files from another option file. For example, to include `/etc/mysql/dbserver1.cnf`, an option file could contain:

```
[mariadb]
...
!include /etc/mysql/dbserver1.cnf
```

Including Option File Directories

It is also possible to include all option files in a directory from another option file. For example, to include all option files in `/etc/my.cnf.d/`, an option file could contain:

```
[mariadb]
...
!includedir /etc/my.cnf.d/
```

The option files within the directory are read in alphabetical order.

All option file names must end in `.cnf` on Unix-like operating systems. On Windows, all option file names must end in `.cnf` or `.ini`.

> **CURRENT**
>
> If a `.cnf` file cannot be read an executable (a MariaDB server or a client tool) will exit with an error. One can use `?includedir` to skip unreadable files without failing out.
>
> **< 11.4.10, < 11.8.6**
>
> If a `.cnf` file cannot be read an executable (a MariaDB server or a client tool) will exit with an error.

Checking Program Options

You can check which options a given program is going to use by using the –print-defaults command-line argument:

Option	Description
–print-defaults	Read options from option files, print all option values, and then exit the program.

This command-line argument can be used with most of MariaDB's command-line tools, not just mariadbd. It must be given as the first argument on the command-line:

```
$ mariadb-dump --print-defaults
mariadb-dump would have been started with the following arguments:
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem --ssl_key=/etc/my.cnf.d/certificates/client-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem --ssl-verify-server-cert --max_allowed_packet=1G
```

You can also check which options a given program is going to use by using the my_print_defaults utility, and providing the names of the option groups that the program reads:

```
$ my_print_defaults mariadb-dump client client-server client-mariadb
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem
--ssl_key=/etc/my.cnf.d/certificates/client-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
--ssl-verify-server-cert
--max_allowed_packet=1GB
```

The `my_print_defaults` utility's `--mariadbd` command-line option provides a shortcut to refer to all of the server option groups:

```
$ my_print_defaults --mysqld
--log_bin=mariadb-bin
--log_slave_updates=ON
--ssl_cert=/etc/my.cnf.d/certificates/server-cert.pem
--ssl_key=/etc/my.cnf.d/certificates/server-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
```

Verifying Option File Sources in Enterprise Server

After modifying a configuration file in Enterprise Server, you can determine the source of a system variable by querying the `INFORMATION_SCHEMA.SYSTEM_VARIABLES` table.

Check a specific variable

```
SELECT VARIABLE_NAME, GLOBAL_VALUE, GLOBAL_VALUE_PATH
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES
WHERE VARIABLE_NAME = 'innodb_buffer_pool_size';   -- replace with your variable
```

Explanation of columns:

- `GLOBAL_VALUE_PATH`: Full path to the configuration file that set this value (e.g. `/etc/my.cnf.d/mariadb-enterprise.cnf`). Returns `NULL` if not set in any config file.
- `GLOBAL_VALUE_ORIGIN`: Shows the origin (config file, a compile-time default, or a command line, etc.).

The `global_value_path` column, introduced in MariaDB 10.5.0, shows the full path to the configuration file from which the variable's value was loaded. This is especially helpful in environments with multiple option files as it enables you to determine which configuration file is currently in effect for a given system setting.

Note: The `global_value_path` column requires MariaDB ES Server 10.5.0 or later. On previous versions, this column doesn't exist.

View all variable set from configuration files

To view all system variables that were set from configuration files, you can run the following:

```
SELECT VARIABLE_NAME, GLOBAL_VALUE, GLOBAL_VALUE_PATH
FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES
WHERE GLOBAL_VALUE_PATH IS NOT NULL;
```

This query returns all variables with values loaded from option files, along with their file paths.

Obfuscated Authentication Credential Option File

MySQL supports an obfuscated authentication credential option file called `.mylogin.cnf` that is created with mysql_config_editor.

MariaDB and MariaDB Enterprise Server do not support this feature. The passwords in MySQL's `.mylogin.cnf` are only obfuscated, rather than encrypted, so the feature does not really add much from a security perspective. It is more likely to give users a false sense of security, rather than to seriously protect them.

Option Prefixes

MariaDB supports certain prefixes that can be used with options. The supported option prefixes are:

Option Prefix	Description
autoset	Sets the option value automatically. Only supported for certain options.
disable	For all boolean options, disables the setting (equivalent to setting it to 0). Same as skip.
enable	For all boolean options, enables the setting (equivalent to setting it to 1).
loose	Don't produce an error if the option doesn't exist.
maximum	Sets the maximum value for the option.
skip	For all boolean options, disables the setting (equivalent to setting it to 0). Same as disable.

For example:

```
[mariadb]
...
# determine a good value for open_files_limit automatically
autoset_open_files_limit

# disable the unix socket plugin
disable_unix_socket

# enable the slow query log
enable_slow_query_log

# don't produce an error if these options don't exist
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
loose_file_key_management_encryption_algorithm = AES_CTR

# set max_allowed_packet to maximum value
maximum_max_allowed_packet

# disable external locking for MyISAM
skip_external_locking
```

Dashes and Underscores

Dashes (`-`) and underscores (`_`) **in option names** are interchangeable. Both variants can be used, for example:

```
[mariadbd]
debug-no-sync
debug_no_sync
```

The same is true for specifying **options on the command line**, for example:

```
mariadbd --debug-no-sync
mariadbd --debug_no_sync
```

> **Note:**
>
> In option files, however, you must omit the leading double-dash (`--`).

This is only different when referring to system variables at runtime. Here, only underscores can be used, for example:

```
MariaDB [(none)]> SELECT @debug_no_sync;
+----------------+
| @debug_no_sync |
+----------------+
| NULL           |
+----------------+
1 row in set (0.002 sec)

MariaDB [(none)]> SELECT @debug-no-sync;
ERROR 1054 (42S22): Unknown column 'no' in 'SELECT'
```

If an option is not explicitly set, the server or client uses the default value for that option.

MariaDB Server Options

MariaDB Server options can be set in server option groups.

For a list of options that can be set for MariaDB Server, see the list of options available for mariadbd.

Most of the server system variables can also be set in MariaDB's option file.

MariaDB Client Options

MariaDB client options can be set in client option groups.

See the specific page for each client program to determine what options are available for that program.

Example Option Files

Most MariaDB installations include a sample MariaDB option file called `my-default.cnf`.

In source distributions, the sample option files are usually found in the `support-files` directory, and in other distributions, in the `share/mysql` directory that is relative to the MariaDB base installation directory.

You can copy one of these sample MariaDB option files and use it as the basis for building your server's primary MariaDB option file.

Example Minimal Option File

Minimal `my.cnf` file that you can use to test MariaDB:

```
[client-server]
# Uncomment these if you want to use a nonstandard connection to MariaDB
#socket=/tmp/mysql.sock
#port=3306

# This will be passed to all MariaDB clients
[client]
#password=my_password

# The MariaDB server
[mysqld]
# Directory where you want to put your data
data=/usr/local/mysql/var
# Directory for the errmsg.sys file in the language you want to use
language=/usr/local/share/mysql/english

# This is the prefix name to be used for all log, error and replication files
log-basename=mysqld

# Enable logging by default to help find problems
general-log
log-slow-queries
```

Example Hybrid Option File

The following is an extract of an option file that one can use if one wants to work with both MySQL and MariaDB.

```
# Example mysql config file.

[client-server]
socket=/tmp/mysql-dbug.sock
port=3307

# This will be passed to all mariadb clients
[client]
password=my_password

# Here are entries for some specific programs
# The following values assume you have at least 32M ram

# The MariaDB server
[mysqld]
temp-pool
key_buffer_size=16M
datadir=/my/mysqldata
loose-innodb_file_per_table

[mariadb]
datadir=/my/data
default-storage-engine=aria
loose-mutex-deadlock-detector
max-connections=20

[mariadb-5.5]
language=/my/maria-5.5/sql/share/english/
socket=/tmp/mysql-dbug.sock
port=3307

[mariadb-10.1]
language=/my/maria-10.1/sql/share/english/
socket=/tmp/mysql2-dbug.sock

[mysqldump]
quick
max_allowed_packet=16M

[mysql]
no-auto-rehash
loose-abort-source-on-error
```

MariaDB Environment Variables

MariaDB makes use of numerous environment variables that may be set on your system. Environment variables have the lowest precedence, so any options set on the command line or in an option file will take precedence.

It's usually better not to rely on environment variables, and to rather set the options you need directly, as this makes the system a little more robust and easier to administer.

Here is a list of environment variables used by MariaDB:

Environment Variable	Description
`HOME`	Default directory for the mysql_history file.
`MYSQL_DEBUG`	Debug trace options used when debugging.
`MYSQL_GROUP_SUFFIX`	In addition to the given option groups, also read groups with this suffix.
`MYSQL_HISTFILE`	Path to the mysql_history file, overriding the `$HOME/.mysql_history` setting.
`MYSQL_HOME`	Path to the directory containing the my.cnf file used by the server.
`MYSQL_HOST`	Default host name used by the mariadb command line client.
`MYSQL_PS1`	Command prompt for use by the mariadb command line client.
`MYSQL_PWD`	Default password when connecting to `mysqld`. It is strongly recommended to use a more secure method of sending the password to the server.
`MYSQL_TCP_PORT`	Default TCP/IP port number.
`MYSQL_UNIX_PORT`	On Unix, default socket file used for localhost connections.
`PATH`	Path to directories that hold executable programs (such as the mariadb client, mariadb-admin), so that these can be run from any location.
`TMPDIR`	Directory where temporary files are created.
`TZ`	Local time zone.
`UMASK`	Creation mode when creating files. See Specifying Permissions for Schema (Data) Directories and Tables.
`UMASK_DIR`	Creation mode when creating directories. See Specifying Permissions for Schema (Data) Directories and Tables.
`USER`	On Windows, up to MariaDB 5.5, the default user name when connecting to the mysqld server. API GetUserName() is used in later versions.

Atomic Write Support

> **Note:**
>
> For the OS-level meaning of `O_DIRECT` and the other `innodb_flush_method` values mentioned on this page, see Storage I/O: Buffering and Persistence.

Partial Write Operations

When Innodb writes to the filesystem, there is generally no guarantee that a given write operation will be complete (not partial) in cases of a poweroff event, or if the operating system crashes at the exact moment a write is being done.

Without detection or prevention of partial writes, the integrity of the database can be compromised after recovery.

`innodb_doublewrite` –an Imperfect Solution

Since its inception, Innodb has had a mechanism to detect and ignore partial writes via the InnoDB Doublewrite Buffer (also `innodb_checksum` can be used to detect a partial write).

Doublewrites, controlled by the innodb_doublewrite system variable, comes with its own set of problems. Especially on SSD, writing each page twice can have detrimental effects (write leveling).

Atomic Write - a Faster Alternative to `innodb_doublewrite`

A better solution is to directly ask the filesystem to provide an atomic (all or nothing) write guarantee. Currently this is only available on a few SSD cards.

Enabling Atomic Writes from MariaDB 10.2

When starting, MariaDB 10.2 and beyond automatically detects if any of the supported SSD cards are used.

When opening an InnoDB table, there is a check if the tablespace for the table is on a device that supports atomic writes and if yes, it will automatically enable atomic writes for the table. If atomic writes support is not detected, the doublewrite buffer will be used.

One can disable atomic write support for all cards by setting the variable innodb-use-atomic-writes to `OFF` in your my.cnf file. It's `ON` by default.

Enabling Atomic Writes in MariaDB 5.5 to MariaDB 10.1

To use atomic writes instead of the doublewrite buffer, add:

```
innodb_use_atomic_writes = 1
```

to the `my.cnf` config file.

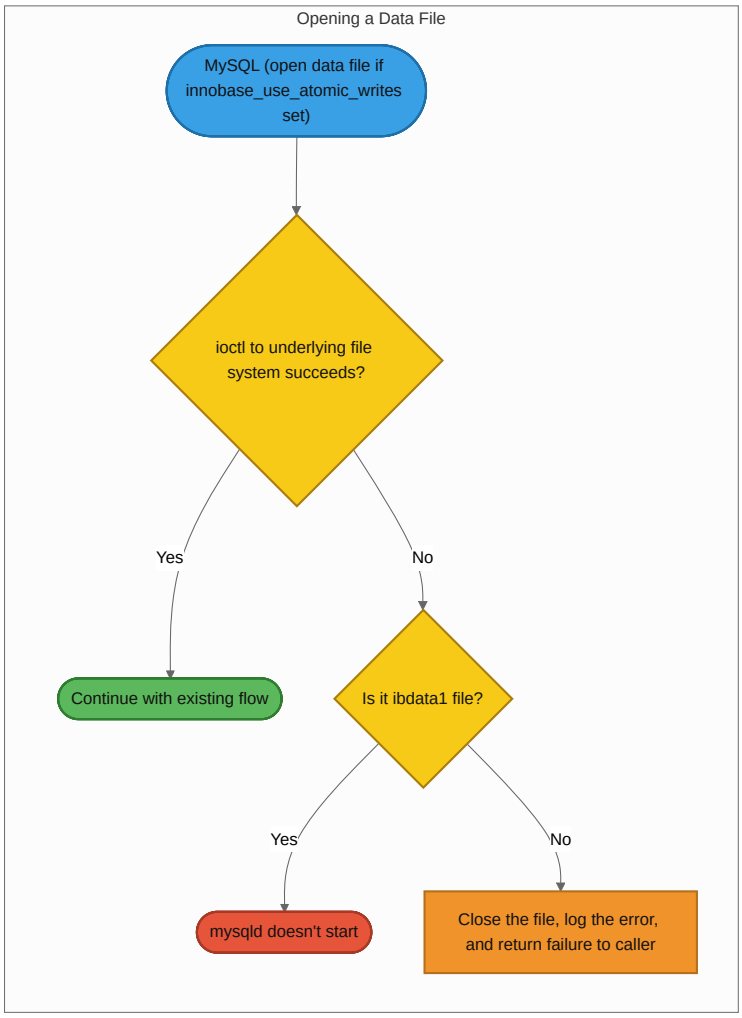
Note that atomic writes are only supported on Fusion-io devices that use the NVMFS file system in these versions of MariaDB.

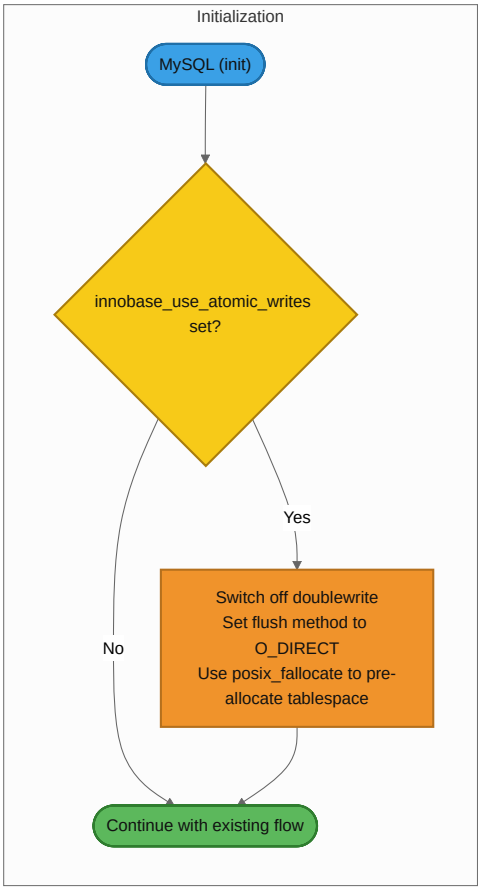
About innodb_use_atomic_writes (in MariaDB 5.5 to MariaDB 10.1)

The following happens when atomic writes are enabled

- if innodb_flush_method is neither `O_DIRECT`, `ALL_O_DIRECT`, or `O_DIRECT_NO_FSYNC`, it is switched to `O_DIRECT`
- innodb_use_fallocate is switched `ON` (files are extended using `posix_fallocate` rather than writing zeros behind the end of file)
- Whenever an Innodb datafile is opened, a special `ioctl()` is issued to switch on atomic writes. If the call fails, an error is logged and returned to the caller. This means that if the system tablespace is not located on an atomic write capable device or filesystem, InnoDB/XtraDB will refuse to start.
- if innodb_doublewrite is set to `ON`, `innodb_doublewrite` will be switched `OFF` and a message written to the error log.

Here is a flowchart showing how atomic writes work inside InnoDB:





Initialization checks the atomic-writes setting before continuing, while opening a data file checks the ioctl result, treating a failed ibdata1 open as fatal and any other file as a closable error.

Devices that Support Atomic Writes with MariaDB

MariaDB currently supports atomic writes on the following devices:

- Fusion-io devices with the NVMFS file system . MariaDB 5.5 and above.
- Shannon SSD. MariaDB 10.2 and above.

Configuring Linux for MariaDB

Linux kernel settings

IO scheduler

For optimal IO performance running a database on modern hardware we recommend using the *none* (previously called *noop*) scheduler.

Recommended schedulers are *none*, for SSDs and NVMes, and *mq-deadline* (previously called *deadline*) for hard disks.

You can check your scheduler setting with:

```
cat /sys/block/${DEVICE}/queue/scheduler
```

For instance, it should look like this output:

```
cat /sys/block/vdb/queue/scheduler
[none] mq-deadline kyber bfq
```

Older kernels may look like:

```
cat /sys/block/sda/queue/scheduler
[noop] deadline cfq
```

Writing the new scheduler name to the same `/sys` node will change the scheduler:

```
echo noop >  /sys/block/vdb/queue/scheduler
```

The impact of schedulers depend significantly on workload and hardware. You can measure the IO-latency using the biolatency bcc-tools script with an aim to keep the mean as low as possible.

Resource Limits

Configuring the Open Files Limit

By default, the system limits how many open file descriptors a process can have open at one time. It has both a soft and hard limit. On many systems, both the soft and hard limit default to 1024. On an active database server, it is very easy to exceed 1024 open file descriptors. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using mysqld_safe or mariadbd-safe to start `mysqld`, then see the instructions at mariadbd-safe: Configuring the Open Files Limit.

If you are using systemd to start `mysqld`, then see the instructions at systemd: Configuring the Open Files Limit.

Otherwise, you can set the soft and hard limits for the `mysql` user account by adding the following lines to /etc/security/limits.conf:

```
mysql soft nofile 65535
mysql hard nofile 65535
```

After the system is rebooted, the `mysql` user should use the new limits, and the user's `ulimit` output should look like the following:

```
$ ulimit -Sn
65535
$ ulimit -Hn
65535
```

Configuring the Core File Size

By default, the system limits the size of core files that could be created. It has both a soft and hard limit. On many systems, the soft limit defaults to 0. If you want to enable core dumps, then you may need to increase this. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using mysqld_safe or mariadbd-safe to start `mysqld`, then see the instructions at mariadb-safe: Configuring the Core File Size.

If you are using systemd to start `mysqld`, then see the instructions at systemd: Configuring the Core File Size.

Otherwise, you can set the soft and hard limits for the `mysql` user account by adding the following lines to /etc/security/limits.conf:

```
mysql soft core unlimited
mysql hard core unlimited
```

After the system is rebooted, the `mysql` user should use the new limits, and the user's `ulimit` output should look like the following:

```
$ ulimit -Sc
unlimited
$ ulimit -Hc
unlimited
```

Swappiness

See configuring swappiness.

Configuring MariaDB for Optimal Performance

This article will help you configure MariaDB for optimal performance.

By default, MariaDB is configured to work on a desktop system and therefore use relatively few resources. To optimize installation for a dedicated server, you have to do a few minutes of work.

For this article we assume that you are going to run MariaDB on a dedicated server.

Feel free to update this article if you have more ideas.

my.cnf Files

MariaDB is normally configured by editing the my.cnf file. In the next section you have a list of variables that you may want to configure for dedicated MariaDB servers.

InnoDB Storage Engine

InnoDB is normally the default storage engine with MariaDB.

- You should set innodb_buffer_pool_size to about 80% of your memory. The goal is to ensure that 80 % of your working set is in memory.

The other most important InnoDB variables are:

- innodb_log_file_size
- innodb_flush_method
- innodb_thread_sleep_delay

Some other important InnoDB variables:

- innodb_max_dirty_pages_pct_lwm
- innodb_read_ahead_threshold
- innodb_buffer_pool_instances. Deprecated and ignored from MariaDB 10.5.1.
- innodb_adaptive_max_sleep_delay. Deprecated and ignored from MariaDB 10.5.5.
- innodb_thread_concurrency. Deprecated and ignored from MariaDB 10.5.5.

Aria Storage Engine

- MariaDB uses by default the Aria storage engine for internal temporary files. If you have many temporary files, you should set aria_pagecache_buffer_size to a reasonably large value so that temporary overflow data is not flushed to disk. The default is 128M.

You can check if Aria is configured properly by executing:

```
MariaDB [test]> show global status like "Aria%";
```

```
+----------------------------------+-------+
| Variable_name                    | Value |
+----------------------------------+-------+
| Aria_pagecache_blocks_not_flushed | 0     |
| Aria_pagecache_blocks_unused      | 964   |
| Aria_pagecache_blocks_used        | 232   |
| Aria_pagecache_read_requests      | 9598  |
| Aria_pagecache_reads              | 0     |
| Aria_pagecache_write_requests     | 222   |
| Aria_pagecache_writes             | 0     |
| Aria_transaction_log_syncs        | 0     |
+----------------------------------+-------+
```

If `Aria_pagecache_reads` is much smaller than `Aria_pagecache_read_request` and `Aria_pagecache_writes` is much smaller than Aria_pagecache_write_request#, then your setup is good. If the aria_pagecache_buffer_size is big enough, the two variables should be 0, like above.

MyISAM

- If you don't use MyISAM tables explicitly (true for most MariaDB 10.4+ users), you can set key_buffer_size to a very low value, like 64K.

Using in memory temporary tables

Using memory tables for internal temporary results can speed up execution.
However, if the memory table gets full, then the memory table will be moved to disk, which can hurt performance.

You can check how the internal memory tables are performing by executing:

```
MariaDB [test]> show global status like "Created%tables%";
```

```
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| Created_tmp_disk_tables | 1     |
| Created_tmp_tables      | 2     |
+-------------------------+-------+
```

`Created_tmp_tables` is the total number of internal temporary tables created as part of executing queries like SELECT. `Created_tmp_disk_tables` shows how many of these did hit the storage.

You can increase the storage for internal temporary tables by setting max_heap_table_size and tmp_memory_table_size high enough. These values are per connection.

Lots of Connections

A Lot of Fast Connections + Small Set of Queries + Disconnects

- If you are doing a lot of fast connections / disconnects, you should increase back_log and if you are running MariaDB 10.1 or below thread_cache_size.
- If you have a lot (> 128) of simultaneous running fast queries, you should consider setting thread_handling to `pool_of_threads`.

Connecting From a Lot of Different Machines

- If you are connecting from a lot of different machines you should increase host_cache_size to the max number of machines (default 128) to cache the resolving of hostnames. If you don't connect from a lot of machines, you can set this to a very low value!

Configuring Swappiness

Why to Avoid Swapping

Obviously, accessing swap memory from disk is far slower than accessing RAM directly. This is particularly bad on a database server because:

- MariaDB's internal algorithms assume that memory is not swap, and are highly inefficient if it is. Some algorithms are intended to avoid or delay disk IO, and use memory where possible - performing this with swap can be worse than just doing it on disk in the first place.
- Swap increases IO over just using disk in the first place as pages are actively swapped in and out of swap. Even something like removing a dirty page that is no longer going to be stored in memory, while designed to improve efficiency, will under a swap situation cost more IO.
- Database locks are particularly inefficient in swap. They are designed to be obtained and released often and quickly, and pausing to perform disk IO will have a serious impact on their usability.

The main way to avoid swapping is to make sure you have enough RAM for all processes that need to run on the machine. Setting the system variables too high can mean that under load the server runs short of memory, and needs to use swap. So understanding what settings to use and how these impact your server's memory usage is critical.

Setting Swappiness on Linux

Linux has a swappiness setting which determines the balance between swapping out pages (chunks of memory) from RAM to a preconfigured swap space on the hard drive.

The setting is from `0` to `100`, with lower values meaning a lower likelihood of swapping. The default is usually `60` –you can check this by running:

```
sysctl vm.swappiness
```

The default setting encourages the server to use swap. Since there probably won't be much else on the database server besides MariaDB processes to put into swap, you'll probably want to reduce this to zero to avoid swapping as much as possible. You can change the default by adding a line to the `sysctl.conf` file (usually found in `/etc/sysctl.conf`).

To set the swappiness to zero, add the line:

```
vm.swappiness = 0
```

This normally takes effect after a reboot, but you can change the value without rebooting as follows:

```
sysctl -w vm.swappiness=0
```

Since RHEL 6.4, setting swappiness=0 more aggressively avoids swapping out, which increases the risk of OOM killing under strong memory and I/O pressure.

A low swappiness setting is recommended for database workloads. For MariaDB databases, it is recommended to set swappiness to a value of 1.

```
vm.swappiness = 1
```

Disabling Swap Altogether

While some disable swap altogether, and you certainly want to avoid any database processes from using it, it can be prudent to leave some swap space to at least allow the kernel to fall over gracefully should a spike occur. Having emergency swap available at least allows you some scope to kill any runaway processes.

Fusion-io

See Fusion-io Introduction.

Fusion-io develops PCIe based NAND flash memory cards and related software that can be used to speed up MariaDB databases.

This page is licensed: CC BY-SA / Gnu FDL

Fusion-io Introduction

The ioDrive branded products can be used as block devices (super-fast disks) or to extend basic DRAM memory. ioDrive is deployed by installing it on an x86 server and then installing the card driver under the operating system.

All main line 64-bit operating systems and hypervisors are supported: RHEL, CentOS, SuSe, Debian, OEL etc. and VMware, Microsoft Windows/Server etc. Drivers and their features are constantly developed further.

ioDrive cards support software RAID and you can combine two or more physical cards into one logical drive. Through ioMemory SDK and its APIs, one can integrate and enable more thorough interworking between your own software and the cards - and cut latency.

The key differentiator between a Fusion-io and a legacy SSD/HDD is the following: **A Fusion-io card is connected directly on the system bus (PCIe)**, this enables high data transfer throughput (1.5 GB/s, 3.0 GB/s or 6GB/s) and the fast direct memory access (DMA) method can be used to transfer data. The ATA/SATA protocol stack is omitted and therefore latency is cut short. Fusion-io performance is dependent on server speed: the faster processors and the newer PCIe-bus version you have, the better is the ioDrive performance. Fusion-io memory is non-volatile, in other words, data remains on the card even when the server is powered off.

Use Cases

1. You can start by using ioDrive for database files that need heavy random access.
2. Whole database on ioDrive.
3. In some cases, Fusion-io devices allow for atomic writes, which allows the server to safely disable the doublewrite buffer.
4. Use ioDrive as a write-through read cache. This is possible on server level with Fusion-io directCache software or in VMware environments using ioTurbine software or the ioCache bundle product. Reads happen from ioDrive and all writes go directly to your SAN or disk.
5. Highly Available shared storage with ION. Have two different hosts, Fusion-io cards in them and share/replicate data with Fusion-io's ION software.
6. The luxurious Platinum setup: MariaDB Galera Cluster running on Fusion-io SLC cards on several hosts.

Atomic Writes

Starting with MariaDB 5.5.31, MariaDB Server supports atomic writes on Fusion-io devices that use the NVMFS (formerly called DirectFS) file system. Unfortunately, NVMFS was never offered under 'General Availability', and SanDisk declared that NVMFS would reach end-of-life in December 2015. Therefore, NVMFS support is no longer offered by SanDisk.

MariaDB Server does not currently support atomic writes on Fusion-io devices with any other file systems.

See atomic write support for more information about MariaDB Server's atomic write support.

Future Suggested Development

- Extend InnoDB disk cache to be stored on Fusion-io acting as extended memory.

Settings For Best Performance

Fusion-io memory can be formatted with different sector size of either 512 or 4096 bytes. Bigger sectors are expected to be faster, but only if I/O is done in blocks of 4KB or multiples of that. Speaking of MariaDB: if only InnoDB data files are stored in Fusion-io memory, all I/O is done in blocks of 16K and thus 4K sector size can be used. If the InnoDB redo log (I/O block size: 512 bytes) goes to the same Fusion-io memory, then short sectors should be used.

Note: XtraDB has the experimental feature of an increased InnoDB log block size of 4K. If this is enabled, then both redo log I/O and page I/O in InnoDB will match a sector size of 4K.

As of file systems: currently XFS is expected to yield the best performance with MariaDB. However depending on the exact kernel version and version of XFS code in use, one might be affected by a bug that severely limits XFS

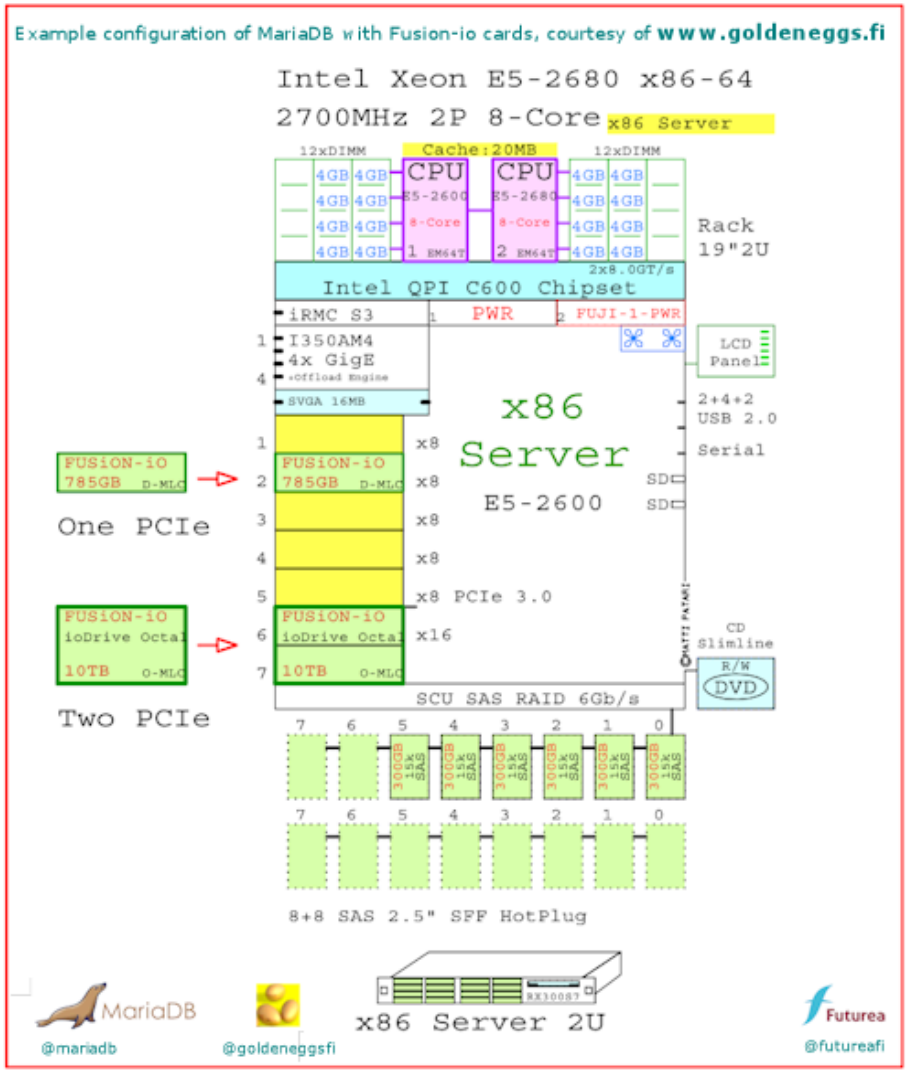
performance in concurrent environments. This has been fixed in kernel versions above 3.5 or RHEL6 kernels kernel-2.6.32-358 or later (because of bug 807503 being fixed).

For the pitbull machine where I have run such tests, ext4 was faster than xfs for 32 or more threads:

- up to 8 threads xfs was few percent faster (10% on average).
- at 16 threads it was a draw (2036 tps vs. 2070 tps).
- at 32 threads ext4 was 28% faster (2345 tps vs. 1829 tps).
- at 64 threads ext4 was even 47% faster (2362 tps vs. 1601 tps).
- at higher concurrency ext4 lost its bite, but was still constantly better than xfs.

Those numbers are for spinning disks. I guess for Fusion-io memory the XFS numbers will be even worse.

Example Configuration



GE-Fusionio-MariaDB

Card Models

There are several card models. ioDrive is older generation, ioDrive2 is newer. SLC sustains more writes. MLC is good enough for normal use.

1. ioDrive2, capacities per card 365GB, 785GB, 1.2TB with MLC. 400GB and 600GB with SLC, performance up to 535000 IOPS & 1.5GB/s bandwidth

2. ioDrive2 Duo, capacities per card 2.4TB MLC and 1.2TB SLC, performance up to 935000 IOPS & 3.0GB/s bandwidth
3. ioDrive, capacities per card 320GB, 640GB MLC and 160GB, 320GB SLC, performance up to 145000 IOPS & 790MB/s bandwidth
4. ioDrive Duo, capacities per card 640GB, 1.28TB MLC and 320GB, 640GB SLC, performance up to 285000 IOPS & 1.5GB/s bandwidth
5. ioDrive Octal, capacities per card 5TB and 10TB MLC, performance up to 1350000 IOPS & 6.7GB/s bandwidth
6. ioFX, a 420GB QDP MLC workstation product, 1.4GB/s bandwidth
7. ioCache, a 600GB MLC card with ioTurbine software bundle that can be used to speed up VMware based virtual hosts.
8. ioScale, 3.2TB card, building block to enable all-flash data center build out in hyperscale web and cloud environments. Product has been developed in co-operation with Facebook.

Additional Software

- directCache - transforms ioDrive to work as a read cache in your server. Writes go directly to your SAN
- ioTurbine - read cache software for VMware
- ION - transforms ioDrive into a shareable storage
- ioSphere - software to manage and monitor several ioDrives

Upgrading on Linux

See Upgrading Between Major MariaDB Versions.

Upgrade between major MariaDB versions, which is normally straightforward thanks to backward-compatible data files, connection protocol, and replication.

See Upgrading Between Minor MariaDB Versions.

Step-by-step minor version upgrade (e.g., 11.4.4 to 11.4.5) for MariaDB Community Server on Linux using YUM, APT, or ZYpp — backup, stop, upgrade packages, restart, and run mariadb-upgrade.

This page is licensed: CC BY-SA / Gnu FDL

Upgrading Between Major MariaDB Versions

MariaDB is designed to allow easy upgrades. You should be able to trivially upgrade from ANY earlier MariaDB version to the latest one (for example MariaDB 10.3.x to MariaDB 10.11.x), usually in a few seconds. This is also mainly true for any MySQL version < 8.0 to MariaDB 10.4 and up.

Upgrades are normally easy because:

- All MariaDB table data files are backward compatible
- The MariaDB connection protocol is backward compatible. You don't normally need to upgrade any of your old clients to be able to connect to a newer MariaDB version.
- The MariaDB replica can be of any newer version than the primary.

MariaDB Corporation regularly runs tests to check that one can upgrade from MariaDB 5.5 to the latest MariaDB version without any trouble. All older versions should work too (as long as the storage engines you were using are still around).

Note that if you are using MariaDB Galera Cluster, you have to follow the Galera upgrading instructions!

Requirements for Doing an Upgrade Between Major Versions

- Galera Cluster Users (Upgrading to 12.3+): You must manually install the `mariadb-server-galera` (or `MariaDB-server-galera`) package during the upgrade. Because the automatic dependency has been removed, a standard upgrade will not pull in the necessary cluster management components, which may prevent your cluster from bootstrapping.
- Go through the individual version upgrade notes (listed below) to look for any major changes or configuration options that have changed.
- Ensure that the target MariaDB version supports the storage engines you are using. For example, in 10.5 TokuDB is not supported.
- Back up the database (just in case). At least, take a copy of the `mysql` system database directory under the data directory with mariadb-dump –add-drop-table mysql (called `mysqldump` in MariaDB 10.3 and earlier) as most of the upgrade changes are done there (adding new fields and new system tables etc).
- Cleanly shutdown the server. This is necessary because even if data files are compatible between versions, recovery logs may not be.
  - Ensure that the innodb_fast_shutdown variable is not 2 (fast crash shutdown). The default of this variable is `1`.
  - innodb_force_recovery must be less than `3`.

Note that rpms don't support upgrading between major versions, only minor like 10.4.1 to 10.4.2. If you are using rpms, you should de-install the old MariaDB rpms and install the new MariaDB rpms before running mariadb-upgrade. Note that when installing the new rpms, mariadb-upgrade may be run automatically. There is no problem with running mariadb-upgrade many times.

Recommended Steps

- If you have a primary-replica setup, first upgrade one replica and when you have verified that the replica works well, upgrade the rest of the replicas (if any). Then upgrade one replica to primary, upgrade the primary, and change the replica to a primary.
- If you don't have a primary-replica setup, then take a backup, shutdown MariaDB and do the upgrade.

Step by Step Instructions for Upgrades

- Upgrade MariaDB binaries and libraries, preferably without starting MariaDB.
- If the MariaDB server process, mariadbd was not started as part of the upgrade, start it by executing `mariadbd --skip-grant-tables`. This may produce some warnings about some system tables not being up to date, but you can ignore these for now as mariadb-upgrade will fix that.
- Run mariadb-upgrade
- Restart MariaDB server.

Work Done by mariadb-upgrade

The main work done when upgrading is done by running mariadb-upgrade. The main things it does are:

- Updating the system tables in the `mysql` database to the newest version. This is very quick.
- mariadb-upgrade also runs mariadb-check –check-upgrade to check if there have been any collation changes between the major versions. This recreates indexes in old tables that are using any of the changed collations. This can take a bit of time if there are a lot of tables or there are many tables which used the changed collation. The last time a collation changed was in MariaDB/MySQL 5.1.23.

Post Upgrade Work

Check the MariaDB error log for any problems during upgrade. If there are any warnings in the log files, do your best to get rid of them!

The common warnings/errors are:

- Using obsolete options. If this is the case, remove them from your my.cnf files.
- Check the manual for new features that have been added since your last MariaDB version.
- Test that your application works as before. The main difference from before is that because of optimizer improvements your application should work better than before, but in some rare cases the optimizer may get something wrong. In this case, you can try to use explain, optimizer trace or optimizer_switch to fix the queries.

If Something Goes Wrong

- First, check the MariaDB error log to see if you are using configure options that are not supported anymore.
- Check the upgrade notices for the MariaDB release that you are upgrading to.
- File an issue in the MariaDB bug tracker so that we know about the issue and can provide a fix to make upgrades even better.
- Add a comment to this manual entry for how we can improve it.

Disaster Recovery

In the unlikely event something goes wrong, you can try the following:

- Remove the InnoDB tables from the `mysql` data directory. They are:
  - `gtid_slave_pos`
  - `innodb_table_stats`
  - `innodb_index_stats`

    - `transaction_registry`

- Move the `mysql` data directory to `mysql-old` and run mariadb-install-db to generate a new one.
- After the above, you have to add back your old users.
- When done, delete the `mysql-old` data directory.

Downgrading

MariaDB server is not designed for downgrading. That said, in most cases, as long as you haven't run any ALTER TABLE or CREATE TABLE statements and you have a mariadb-dump of your old `mysql` database , you should be able to downgrade to your previous version by doing the following:

- Do a clean shutdown. For this special case you have to set innodb_fast_shutdown to 0,before taking down the new MariaDB server, to ensure there are no redo or undo logs that need to be applied on the downgraded server.
- Delete the tables in the `mysql` database (if you didn't use the option `--add-drop-table` to mariadb-dump)
- Delete the new MariaDB installation
- Install the old MariaDB version
- Start the server with mariadbd –skip-grant-tables
- Install the old `mysql` database
- Execute in the mariadb client FLUSH PRIVILEGES

Upgrading Between Minor MariaDB Versions

These instructions detail a **minor release upgrade** of **MariaDB Community Server** on Linux. A minor release upgrade refers to upgrading within the same release series. For example, upgrading from MariaDB 11.4.4 to MariaDB 11.4.5 without changing the major version. Minor releases typically deliver bug fixes, security patches, and stability improvements.

For Windows, see Upgrading MariaDB on Windows. For major version upgrades (for example, MariaDB 10.11 to MariaDB 11.4), see Upgrading Between Major MariaDB Versions and the per-version guides listed in See Also.

> **Note:**
>
> The examples in this page use MariaDB Community Server 11.4.4 → 11.4.5 as the worked scenario. The same procedure applies to any supported minor-version upgrade within a release series.

Data Backup

Occasionally, issues can be encountered during an upgrade. These issues can even potentially corrupt the database's data files, making it difficult to revert to the previous installation. It is strongly recommended to create a

backup before upgrading. * If the upgrade fails, the backup can be used to restore the database to the previous version of MariaDB Server. * If the upgrade finishes successfully, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, see the Recovery Guide.

1. Take a full backup:

   ```
   sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Replace `mariadb-backup_user` and `mariadb-backup_passwd` with your actual backup user credentials. Confirm successful completion of the backup operation.

2. Prepare the backup so it is ready for immediate restoration if required:

   ```
   sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted. Restore the backup to a non-production instance and verify it before proceeding with the upgrade.

Stop the MariaDB Server Process

Before the new packages are installed, stop the running server.

1. Set the innodb_fast_shutdown system variable to `1` so InnoDB flushes all dirty pages and closes cleanly:

   ```
   SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

   ```
   XA RECOVER;
   ```

   Commit or roll back any open XA transactions before stopping the server.

3. Stop the server process. On distributions that use `systemd` (most supported OSes), manage the server with `systemctl`:

   ```
   sudo systemctl stop mariadb
   ```

Install the New Version

Unlike a major-version upgrade, a minor-version upgrade does **not** require uninstalling the old packages first. The distribution's package manager upgrades the packages in place, while keeping the data directory and configuration files unchanged.

MariaDB Community Server provides a setup script, `mariadb_repo_setup`, that configures the package repository for your distribution. To pin to a specific minor release, pass the full version number to `--mariadb-server-version`, prefixed with `mariadb-`. For example, to install MariaDB 11.4.5 instead of the latest 11.4.x release:

```
--mariadb-server-version="mariadb-11.4.5"
```

To track the latest release in a series rather than pinning to a specific minor, pass only the series:

```
--mariadb-server-version="mariadb-11.4"
```

UPGRADE VIA YUM

Upgrade via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Configure the YUM package repository for the target release. The following example uses MariaDB 11.4.5; adjust the version number for your target release:

   ```
   sudo yum install curl
   ```

   ```
   curl -LsSO https://downloads.mariadb.com/MariaDB/mariadb_repo_setup
   ```

   ```
   chmod +x mariadb_repo_setup
   ```

   ```
   sudo ./mariadb_repo_setup --mariadb-server-version="mariadb-11.4.5"
   ```

   See Pinning the Repository to a Specific Minor Release for more on minor-release pinning.

2. Update MariaDB Community Server and package dependencies:

   ```
   sudo yum update "MariaDB-*" "galera*"
   ```

   Check that the wildcards do not unintentionally match any custom applications.

UPGRADE VIA APT

Upgrade via APT (Debian, Ubuntu)

1. Configure the APT package repository for the target release. The following example uses MariaDB 11.4.5; adjust the version number for your target release:

   ```
   sudo apt install curl
   ```

   ```
   curl -LsSO https://downloads.mariadb.com/MariaDB/mariadb_repo_setup
   ```

   ```
   chmod +x mariadb_repo_setup
   ```

   ```
   sudo ./mariadb_repo_setup --mariadb-server-version="mariadb-11.4.5"
   ```

   ```
   sudo apt update
   ```

2. Upgrade MariaDB Community Server and package dependencies. The `--only-upgrade` flag ensures `apt` does not install new packages, only updates existing ones:

   ```
   sudo apt install --only-upgrade "mariadb-*" "galera*"
   ```

   Check that the wildcards do not unintentionally match any custom applications.

UPGRADE VIA ZYPP

Upgrade via ZYpp (SLES, openSUSE)

1. Configure the ZYpp package repository for the target release. The following example uses MariaDB 11.4.5; adjust the version number for your target release:

```
sudo zypper install curl
```

```
curl -LsSO https://downloads.mariadb.com/MariaDB/mariadb_repo_setup
```

```
chmod +x mariadb_repo_setup
```

```
sudo ./mariadb_repo_setup --mariadb-server-version="mariadb-11.4.5"
```

2. Update MariaDB Community Server and package dependencies:

   ```
   sudo zypper update "MariaDB-*" "galera*"
   ```

   Check that the wildcards do not unintentionally match any custom applications.

Configuration

For platforms that use YUM or ZYpp as a package manager, MariaDB Community Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade. To continue using your customized version, restore it before starting the server. For example, to restore `server.cnf`:

```
sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

On APT-based systems (Debian, Ubuntu), preserved configuration files use the `.dpkg-old` extension instead. The principle is the same: rename and restore as needed.

Now is also the time to make any desired changes to option files such as `my.cnf`, before starting the new server.

Starting the Server

MariaDB Community Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the server using the operating system's default process management system.

For distributions that use `systemd`, manage the server process using `systemctl`:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB ships with a utility that checks for and corrects any compatibility issues introduced by the upgrade. After the server is upgraded and running, run mariadb-upgrade to upgrade the data directory:

```
sudo mariadb-upgrade
```

Note:

Minor-version upgrades do not change the data dictionary. On mariadb-upgrade 2.0 and later, `mariadb-upgrade` detects this automatically and exits immediately with a message confirming no upgrade is needed and this is expected behaviour. Running `mariadb-upgrade` after a minor upgrade is still recommended as a safety check, and is harmless when no work is needed. Use `--force` to run the full check regardless.

Testing

When the upgraded server is up and running, verify it is working and there were no issues during startup.

1. Connect to the server using the mariadb client as the `root@localhost` user:

   ```
   sudo mariadb
   ```

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   Your MariaDB connection id is 9
   Server version: 11.4.5-MariaDB MariaDB Server

   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

   MariaDB [(none)]>
   ```

2. Verify the server version by checking the version system variable:

   ```
   SHOW GLOBAL VARIABLES LIKE 'version';
   ```

   ```
   +---------------+-----------------+
   | Variable_name | Value           |
   +---------------+-----------------+
   | version       | 11.4.5-MariaDB  |
   +---------------+-----------------+
   ```

3. Verify by calling the VERSION() function:

   ```
   SELECT VERSION();
   ```

   ```
   +-----------------+
   | VERSION()       |
   +-----------------+
   | 11.4.5-MariaDB  |
   +-----------------+
   ```

Upgrading MariaDB on Windows

For incompatibilities such as removed features, and changes to variables, see the pages describing changes by version on Upgrading MariaDB.

Minor Upgrades

To install a minor upgrade with MSI, just download the MSI and install it. It will do everything that needs to be done for minor upgrade automatically - shutdown MariaDB service(s), replace executables and DLLs, and start service(s) again.

The rest of the article is dedicated to *major* upgrades, e.g 10.1.x to 10.2.y.

General Information on Upgrade and Version Coexistence

This section assumes MSI installations.

First, check everything listed in the Incompatibilities section of the article relating to the version you are upgrading, for example, Upgrading from MariaDB 10.1 to MariaDB 10.2, to make sure you are prepared for the upgrade.

MariaDB (and also MySQL) allows different versions of the product to co-exist on the same machine, as long as these versions are different either in major or minor version numbers. For example, it is possible to have say MariaDB 5.1.51 and 5.2.6 to be installed on the same machine.

However only a single instance of 5.2 can exist. If for example 5.2.7 is installed on a machine where 5.2.6 is already installed, the installer will just replace 5.2.6 executables with 5.2.7 ones.

Now imagine, that both 5.1 and 5.2 are installed on the same machine and we want to upgrade the database instance running on 5.1 to the new version. In this case special tools are required. Traditionally, mysql_upgrade is used to accomplish this. On Windows, theMySQL upgrade is a complicated multiple-step manual process.

Since MariaDB 5.2.6, the Windows distribution includes tools that simplify migration between different versions and also allow migration between MySQL and
MariaDB.

Note. Automatic upgrades are only possible for DB instances that run as a
Windows service.

General Recommendations

Important: Ignore any statement that tells you to *"just uninstall MySQL and install MariaDB"*. This does not work on Windows, never has, and never will. Keep your MySQL installed until after the database had been converted.

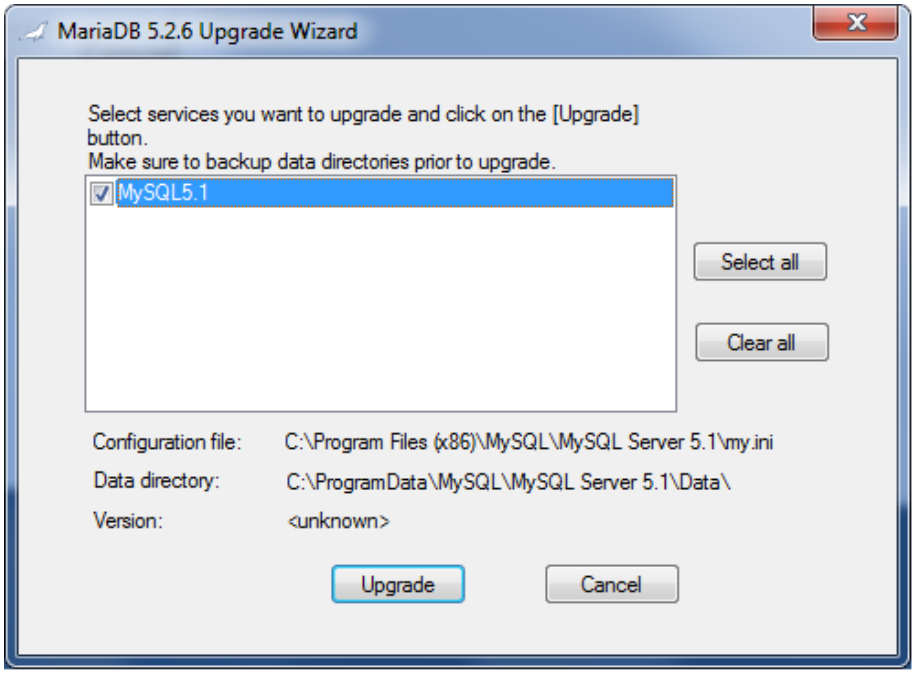
The following install/upgrade sequence is recommended in case of "major" upgrades, like going from 5.3 to 5.5

- Install new version, while still retaining the old one
- Upgrade services one by one, like described later in the document (e.g with mysql_upgrade_service). It is recommended to have services cleanly shut down before the upgrade.
- Uninstall old version when previous step is done.

Note. This recommendation differs from the procedure on Unixes, where the upgrade sequence is "uninstall old version, install new version"

Upgrade Wizard

This is a GUI tool that is typically invoked at the end of a MariaDB installation if upgradable services are found. The UI allows you to select instances you want to upgrade.



UpgradeWizard

`mysql_upgrade_service`

This is a command line tool that performs upgrades. The tool requires full administrative privileges (it has to start and stop services).

Example usage:

```
mysql_upgrade_service --service=MySQL
```

`mysql_upgrade_service` accepts a single parameter — the name of the MySQL or MariaDB service. It performs all the steps to convert a MariaDB/MySQL instance running as the service to the current version.

Migration to 64 bit MariaDB from 32 bit

Earlier we said that only single instance of "MariaDB ." version can be installed on the same machine. This was almost correct, because MariaDB

MSI installations allow 32 and 64-bit versions to be installed on the same machine, and in this case it is possible to have two instances of say 5.2 installed at the same time, an x86 one and an x64 one. One can use the x64 Upgrade wizard to upgrade an instance running as a 32-bit process to run as 64-bit.

Upgrading ZIP-based Installations.

Both UpgradeWizard and mysql_upgrade_service can also be used to upgrade database instances that were installed with the ZIP installation.

Upgrading from MariaDB 11.8 to MariaDB 12.3

This page includes details for upgrading from MariaDB 11.8, the previous long-term maintenance version, to MariaDB 12.3.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 12.3.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
    3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`
4. Install the new version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade, to:
    1. Ensure that the system tables in the mysql database are fully compatible with the new version.
    2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 11.8 and 12.3

On most servers upgrading from 11.8 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
big_tables	Deprecated in MariaDB 10.5.0 and removed in MariaDB 12.0. No longer needed, as the server handles large result sets automatically.
storage_engine	Deprecated alias for `default_storage_engine` since MariaDB 5.5, and removed in MariaDB 12.0. Use default_storage_engine instead.
large_page_size	Read-only variable deprecated in MariaDB 10.5.3 and removed in MariaDB 12.0.

New Reserved Words

`CONVERSION`, `ST_COLLECT`, and `TO_DATE` are now reserved words. This only affects you if you use one of them as an unquoted identifier (for example, a table, column, or variable name) — quote it or rename it before upgrading, otherwise the statement will fail to parse. For the full list of 12.3 changes, see Features in MariaDB 12.3.

Changes in Replication Behavior

> **Warning:**
>
> When upgrading a replica from a pre-12.3 release to MariaDB 12.3.2, the CHANGE MASTER TO … master_use_gtid setting is not carried over and is reset to `DEFAULT`. This is fixed in 12.3.3 via MDEV-39788. After upgrading, check the replication configuration and re-apply `master_use_gtid` if you rely on it. Downgrading is not affected.

Deprecated Options

The `MYSQLD_OPTS` environment variable for the systemd service is deprecated. Place configuration options directly into option files, such as `my.cnf`, instead.

Upgrading from MariaDB 11.4 to MariaDB 11.8

This page includes details for upgrading from MariaDB 11.4 to the subsequent long-term maintenance version, MariaDB 11.8.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.8.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`

2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

4. Install the new version of MariaDB.
   1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade, to:
   1. Ensure that the system tables in the mysql database are fully compatible with the new version.
   2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 11.4 and 11.8

On most servers upgrading from 11.4 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
wsrep_load_data_splitting	Deprecated in MariaDB 10.4, defaults to `OFF`.

Options That Have Changed Default Values

N/A

Changes in Transaction Behavior

In MariaDB 11.8, InnoDB transactions under the Repeatable Read isolation level behave differently due to changes to the innodb_snapshot_isolation handling.

Therefore, in cases where no problem was previously provided, statements that modify data (such as DELETE or UPDATE) may now generate the following error:

```
ERROR 1020 (HY000): Record has changed since last read in table 't'
```

Description

A transaction under the Repeatable Read isolation level runs on a consistent snapshot of the data taken at the time of its initial read. A conflict may be identified when the initial transaction tries to change the same data after the snapshot has been created.

Such conflicts are more rigorously recognized in MariaDB 11.8. For example:

- If another transaction has added, altered, or removed rows in the meantime, a transaction that reads a table and then tries to delete or update data may fail.

- Even if the change impacts rows that weren't visible in the initial snapshot, this may still occur.

Example

```
-- Session 1
BEGIN;
SELECT * FROM t;

-- Session 2
BEGIN;
INSERT INTO t VALUES (2);
COMMIT;

-- Session 1
DELETE FROM t;
-- ERROR 1020 (HY000): Record has changed since last read in table 't'
```

Differences in Behavior by Isolation Level

- **Repeatable Read**
  When a transaction tries to modify data based on an outdated snapshot, the server detects conflicts, rolls back the transactions, and returns `ERROR 1020`.
- **Serializable**
  Conflicting transactions may be blocked earlier due to stricter locking. Depending on the execution sequence, the error may occur in another transaction or be avoided entirely.

Impact

After updating to MariaDB 11.8, applications that depend on Repeatable Read transactions may experience additional `ERROR 1020` failures. This may have an impact on:

- `DELETE` or `UPDATE` operations in bulk
- Workloads with simultaneous changes

For more details, see innodb_snapshot_isolation.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

N/A

Upgrading from MariaDB 11.3 to MariaDB 11.4

This page includes details for upgrading from MariaDB 11.3 to MariaDB 11.4. Note that MariaDB 11.3 is a rolling release, and MariaDB 11.4 is a long-term maintenance release. After MariaDB 11.4.2, one can continue to the next rolling release, 11.5.2, 11.6.2 and so on, or remain on the long-term series, MariaDB 11.4.3. MariaDB 11.4.4 etc.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.6 to MariaDB 10.11 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.4.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
    3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`
4. Install the new version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade, to:
    1. Ensure that the system tables in the mysql database are fully compatible with the new version.
    2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 11.3 and 11.4

Options That Have Been Removed

The following options should be removed if you use them in your option files:

Option	Reason
debug_no_thread_alarm	Unused code.

Upgrading from MariaDB 10.11 to MariaDB 11.4

This page includes details for upgrading from MariaDB 10.11 to the subsequent long-term maintenance version, MariaDB 11.4.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading Galera Cluster section.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaD11.4.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
    3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`
4. Install the new version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade, to:
    1. Ensure that the system tables in the mysql database are fully compatible with the new version.

2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 10.11 and 11.4

On most servers upgrading from 10.11 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
debug_no_thread_alarm	Unused code.
innodb_defragment	Defragmenting InnoDB Tablespaces in this manner no longer supported.
innodb_defragment_fill_factor	Defragmenting InnoDB Tablespaces in this manner no longer supported.
innodb_defragment_fill_factor_n_recs	Defragmenting InnoDB Tablespaces in this manner no longer supported.
innodb_defragment_frequency	Defragmenting InnoDB Tablespaces in this manner no longer supported.
innodb_defragment_n_pages	Defragmenting InnoDB Tablespaces in this manner no longer supported.
innodb_defragment_stats_accuracy	Defragmenting InnoDB Tablespaces in this manner no longer supported.

Options That Have Changed Default Values

Option	Old default	New default
optimizer_switch		See optimizer-switch.
innodb_purge_batch_size	300	1000

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
old_alter_table	Superseded by alter_algorithm.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_purge_rseg_truncate_frequency	The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint, hence this is deprecated and ignored
tx_isolation	Replaced with transaction_isolation to align the option and system variable.
tx_read_only	Replaced with transaction_read_only to align the option and system variable.

Upgrading from MariaDB 10.6 to MariaDB 10.11

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.6 to MariaDB 10.11 with Galera Cluster.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.11. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
    3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`
3. Install the new version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
4. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
5. Start MariaDB.
6. Run mariadb-upgrade, to:
    1. Ensure that the system tables in the mysql database are fully compatible with the new version.
    2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 10.6 and 10.11

On most servers upgrading from 10.6 should be painless. However, there are some things that have changed which could affect an upgrade:

Compression

If a non-zlib compression algorithm was used in InnoDB or Mroonga before upgrading to 10.11, those tables will be unreadable until the appropriate compression library is installed. See Compression Plugins#Upgrading.

Options That Have Changed Default Values

Option	Old default	New default
innodb_buffer_pool_chunk_size	134217728	Autosized
spider_auto_increment_mode	-1	0
spider_bgs_first_read	-1	2
spider_bgs_mode	-1	0
spider_bgs_second_read	-1	100
spider_bka_mode	-1	1
spider_bka_table_name_type	-1	1
spider_buffer_size	-1	16000
spider_bulk_size	-1	16000
spider_bulk_update_mode	-1	0
spider_bulk_update_size	-1	16000
spider_casual_read	-1	0
spider_connect_timeout	-1	6
spider_crd_bg_mode	-1	2
spider_crd_interval	-1	51
spider_crd_mode	-1	1
spider_crd_sync	-1	0
spider_crd_type	-1	2
spider_crd_weight	-1	2
spider_delete_all_rows_type	-1	1
spider_direct_dup_insert	-1	0
spider_direct_order_limit	-1	9223372036854775807
spider_error_read_mode	-1	0
spider_error_write_mode	-1	0
spider_first_read	-1	0
spider_init_sql_alloc_size	-1	1024
spider_internal_limit	-1	9223372036854775807
spider_internal_offset	-1	0
spider_internal_optimize	-1	0
spider_internal_optimize_local	-1	0
spider_load_crd_at_startup	-1	1
spider_load_sts_at_startup	-1	1

Option	Old default	New default
spider_low_mem_read	-1	1
spider_max_order	-1	32767
spider_multi_split_read	-1	100
spider_net_read_timeout	-1	600
spider_net_write_timeout	-1	600
spider_quick_mode	-1	3
spider_quick_page_byte	-1	10485760
spider_quick_page_size	-1	1024
spider_read_only_mode	-1	0
spider_reset_sql_alloc	-1	1
spider_second_read	-1	0
spider_selupd_lock_mode	-1	1
spider_semi_split_read	-1	2
spider_semi_split_read_limit	-1	1
spider_semi_table_lock_connection	-1	1
spider_semi_table_lock	1	0

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_log_write_ahead_size	On Linux and Windows, the physical block size of the underlying storage is instead detected and used.
innodb_version	Redundant
wsrep_replicate_myisam	Use wsrep_mode instead.
wsrep_strict_ddl	Use wsrep_mode instead.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
keep_files_on_create	MariaDB now deletes orphan files, so this setting should never be necessary.

Upgrading from MariaDB 10.5 to MariaDB 10.6

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.5 to MariaDB 10.6 with Galera Cluster.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.6.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
    3. On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`
4. Install the new version of MariaDB.
    1. On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    2. On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    3. On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade, to:
    1. Ensure that the system tables in the mysql database are fully compatible with the new version.
    2. Perform a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 10.5 and 10.6

On most servers upgrading from 10.5 should be painless. However, there are some things that have changed which could affect an upgrade:

The behaviour of sorting non-deterministic variables in a Select query can be changed , see (MDEV-27745)

Reserved Word

- New reserved word: `OFFSET`. This can no longer be used as an identifier without being quoted.

InnoDB COMPRESSED Row Format

From MariaDB 10.6.0 until MariaDB 10.6.5, tables that are of the `COMPRESSED` row format are read-only by default. This was intended to be the first step towards removing write support and deprecating the feature.

This plan has been scrapped, and from MariaDB 10.6.6, `COMPRESSED` tables are no longer read-only by default.

From MariaDB 10.6.0 to MariaDB 10.6.5, set the innodb_read_only_compressed variable to `OFF` to make the tables writable.

Character Sets

From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.

Options That Have Changed Default Values

Option	Old default value	New default value
character_set_client	utf8	utf8mb3
character_set_connection	utf8	utf8mb3
character_set_results	utf8	utf8mb3
character_set_system	utf8	utf8mb3
innodb_flush_method	fsync	O_DIRECT
old_mode	Empty	UTF8_IS_UTF8MB3

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_adaptive_max_sleep_delay	
innodb_background_scrub_data_check_interval	
innodb_background_scrub_data_compressed	
innodb_background_scrub_data_interval	
innodb_background_scrub_data_uncompressed	
innodb_buffer_pool_instances	
innodb_checksum_algorithm	The variable is still present, but the *innodb and *none options have been removed as the crc32 algorithm only is supported from MariaDB 10.6.
innodb_commit_concurrency	
innodb_concurrency_tickets	
innodb_file_format	
innodb_large_prefix	
innodb_lock_schedule_algorithm	

Option	Reason
innodb_log_checksums	
innodb_log_compressed_pages	
innodb_log_files_in_group	
innodb_log_optimize_ddl	
innodb_page_cleaners	
innodb_replication_delay	
innodb_scrub_log	
innodb_scrub_log_speed	
innodb_sync_array_size	
innodb_thread_concurrency	
innodb_thread_sleep_delay	
innodb_undo_logs	

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
wsrep_replicate_myisam	Use wsrep_mode instead.
wsrep_strict_ddl	Use wsrep_mode instead.

Upgrading from MariaDB 11.2 to MariaDB 11.3

This page includes details for upgrading from MariaDB 11.2 to MariaDB 11.3. Note that MariaDB 11.2 is a short-term release, only maintained for one year. MariaDB 11.3 is a rolling release, after 11.3.2 one should upgrade to 11.4.2.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.3. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 11.2 and 11.3

On most servers upgrading from 11.2 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default	New default
optimizer_switch		See optimizer-switch.
session_track_system_variables	autocommit, character_set_client, character_set_connection, character_set_results, time_zone	autocommit, character_set_client, character_set_connection, character_set_results, redirect_url, time_zone

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
date_format	Unused.
datetime_format	Unused.
max_tmp_tables	Unused.
time_format	Unused.
wsrep_causal_reads	Deprecated by wsrep_sync_wait=1.

Upgrading from MariaDB 11.1 to MariaDB 11.2

This page includes details for upgrading from MariaDB 11.1 to MariaDB 11.2. Note that MariaDB 11.1 and MariaDB 11.2 are both short-term releases, only maintained for one year.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.6 to MariaDB 10.11 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.2. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 11.1 and 11.2

On most servers upgrading from 11.1 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default	New default
optimizer_switch		See optimizer-switch.
innodb_purge_batch_size	300	1000

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
old_alter_table	Superseded by alter_algorithm.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_purge_rseg_truncate_frequency	The motivation for introducing this in MySQL seems to have been to avoid stalls due to freeing undo log pages or truncating undo log tablespaces. In MariaDB, innodb_undo_log_truncate=ON should be a much lighter operation because it will not involve any log checkpoint, hence this is deprecated and ignored

Upgrading from MariaDB 10.11 to MariaDB 11.0

This page includes details for upgrading from MariaDB 10.11 to MariaDB 11.0. It is currently incomplete. Note that MariaDB 10.11 is maintained for five years, while MariaDB 11.0 is a short-term maintenance release, only maintained for one year.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.6 to MariaDB 10.7 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.0. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.11 and 11.0

On most servers upgrading from 10.11 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default	New default
innodb_undo_tablespaces	0	3
histogram_type	DOUBLE_PREC_HB	JSON_HB

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_change_buffer_max_size	InnoDB Change Buffer removed
innodb_change_buffering	InnoDB Change Buffer removed

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_defragment	InnoDB Defragmentation is not particularly useful and causes a maintenance burden.
innodb_defragment_n_pages	
innodb_defragment_stats_accuracy	
innodb_defragment_fill_factor_n_recs	
innodb_defragment_fill_factor	
innodb_defragment_frequency	

Option	Reason
innodb_file_per_table	
innodb_flush_method	
innodb_file_per_table	Has been set for many releases. Unsetting (the original InnoDB default) is no longer useful
innodb_flush_method	Mapped it to 4 new boolean parameters that can be changed while the server is running
log_slow_admin_statements	Use log_slow_filter without admin

Upgrading from MariaDB 10.7 to MariaDB 10.8

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.8. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.

- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.7 and 10.8

On most servers upgrading from 10.7 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default value	New default value
innodb_buffer_pool_chunk_size	134217728	Autosized
spider_semi_table_lock	1	0

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_log_write_ahead_size	On Linux and Windows, the physical block size of the underlying storage is instead detected and used.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
keep_files_on_create	MariaDB now deletes orphan files, so this setting should never be necessary.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.8:

- Stored procedures already have support for the IN, OUT and INOUT parameter qualifiers. Added as well for stored functions and (IN only) cursors (MDEV-10654).
- Individual columns in the index can now be explicitly sorted in the ascending or descending order. This can be useful for optimizing certain ORDER BY cases (MDEV-13756, MDEV-26938, MDEV-26939, MDEV-26996).
- See also System Variables Added in MariaDB 10.8.

Upgrading from MariaDB 10.6 to MariaDB 10.7

Note that MariaDB 10.7 is only maintained for one year. MariaDB 10.6 is currently the latest long-term maintenance release.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.6 to MariaDB 10.7 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.7. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.6 and 10.7

On most servers upgrading from 10.6 should be painless. However, there are some things that have changed which could affect an upgrade:

Reserved Words

- ROW_NUMBER is now a reserved word.

Compression

If a non-zlib compression algorithm was used in InnoDB or Mroonga before upgrading to 10.7, those tables will be unreadable until the appropriate compression library is installed. See Compression Plugins#Upgrading.

Options That Have Changed Default Values

Option	Old default	New default
spider_auto_increment_mode	-1	0
spider_bgs_first_read	-1	2
spider_bgs_mode	-1	0
spider_bgs_second_read	-1	100
spider_bka_mode	-1	1
spider_bka_table_name_type	-1	1
spider_buffer_size	-1	16000
spider_bulk_size	-1	16000
spider_bulk_update_mode	-1	0
spider_bulk_update_size	-1	16000
spider_casual_read	-1	0
spider_connect_timeout	-1	6
spider_crd_bg_mode	-1	2
spider_crd_interval	-1	51
spider_crd_mode	-1	1
spider_crd_sync	-1	0
spider_crd_type	-1	2
spider_crd_weight	-1	2
spider_delete_all_rows_type	-1	1
spider_direct_dup_insert	-1	0
spider_direct_order_limit	-1	9223372036854775807
spider_error_read_mode	-1	0
spider_error_write_mode	-1	0
spider_first_read	-1	0
spider_init_sql_alloc_size	-1	1024
spider_internal_limit	-1	9223372036854775807
spider_internal_offset	-1	0
spider_internal_optimize	-1	0
spider_internal_optimize_local	-1	0

Option	Old default	New default
spider_load_crd_at_startup	-1	1
spider_load_sts_at_startup	-1	1
spider_low_mem_read	-1	1
spider_max_order	-1	32767
spider_multi_split_read	-1	100
spider_net_read_timeout	-1	600
spider_net_write_timeout	-1	600
spider_quick_mode	-1	3
spider_quick_page_byte	-1	10485760
spider_quick_page_size	-1	1024
spider_read_only_mode	-1	0
spider_reset_sql_alloc	-1	1
spider_second_read	-1	0
spider_selupd_lock_mode	-1	1
spider_semi_split_read	-1	2
spider_semi_split_read_limit	-1	1
spider_semi_table_lock_connection	-1	1
spider_reset_sql_alloc	-1	1

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
wsrep_replicate_myisam	Use wsrep_mode instead.
wsrep_strict_ddl	Use wsrep_mode instead.

Upgrading from MariaDB 10.4 to MariaDB 10.5

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.4 to MariaDB 10.5 with Galera Cluster.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.5. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mysql_upgrade.

- `mysql_upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.4 and 10.5

On most servers upgrading from 10.4 should be painless. However, there are some things that have changed which could affect an upgrade:

Binary name changes

All binaries previously beginning with mysql now begin with mariadb, with symlinks for the corresponding mysql command.

Usually that shouldn't cause any changed behavior, but when starting the MariaDB server via systemd, or via the mysqld_safe script symlink, the server process will now always be started as `mariadbd`, not `mysqld`.

So anything looking for the `mysqld` name in the system process list, like e.g. monitoring solutions, now needs for `mariadbd` instead when the server / service is not started directly, but via `mysqld_safe` or as a system service.

GRANT PRIVILEGE changes

A number of statements changed the privileges that they require. The old privileges were historically inappropriately chosen in the upstream. 10.5.2 fixes this problem. Note, these changes are incompatible to previous versions. A number of GRANT commands might be needed after upgrade.

- `SHOW BINLOG EVENTS` now requires the `BINLOG MONITOR` privilege (required `REPLICATION SLAVE` prior to 10.5.2).
- `SHOW SLAVE HOSTS` now requires the `REPLICATION MASTER ADMIN` privilege (required `REPLICATION SLAVE` prior to 10.5.2).
- `SHOW SLAVE STATUS` now requires the `REPLICATION SLAVE ADMIN` or the `SUPER` privilege (required `REPLICATION CLIENT` or `SUPER` prior to 10.5.2).
- `SHOW RELAYLOG EVENTS` now requires the `REPLICATION SLAVE ADMIN` privilege (required `REPLICATION SLAVE` prior to 10.5.2).

Options That Have Changed Default Values

Option	Old default value	New default value
innodb_adaptive_hash_index	ON	OFF
innodb_checksum_algorithm	crc32	full_crc32
innodb_log_optimize_ddl	ON	OFF
slave_parallel_mode	conservative	optimistic
performance_schema_max_cond_classes	80	90
performance_schema_max_file_classes	50	80
performance_schema_max_mutex_classes	200	210
performance_schema_max_rwlock_classes	40	50
performance_schema_setup_actors_size	100	-1
performance_schema_setup_objects_size	100	-1

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_checksums	Deprecated and functionality replaced by innodb_checksum_algorithms in MariaDB 10.0.
innodb_idle_flush_pct	Has had no effect since merging InnoDB 5.7 from mysql-5.7.9 (MariaDB 10.2.2).
innodb_locks_unsafe_for_binlog	Deprecated in MariaDB 10.0. Use READ COMMITTED transaction isolation level instead.
innodb_rollback_segments	Deprecated and replaced by innodb_undo_logs in MariaDB 10.0.
innodb_stats_sample_pages	Deprecated in MariaDB 10.0. Use innodb_stats_transient_sample_pages instead.
max_long_data_size	Deprecated and replaced by max_allowed_packet in MariaDB 5.5.
multi_range_count	Deprecated and has had no effect since MariaDB 5.3.
thread_concurrency	Deprecated and has had no effect since MariaDB 5.5.
timed_mutexes	Deprecated and has had no effect since MariaDB 5.5.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_adaptive_max_sleep_delay	No need for thread throttling any more.
innodb_background_scrub_data_check_interval	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_interval	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_compressed	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_uncompressed	Problematic 'background scrubbing' code removed.
innodb_buffer_pool_instances	Having more than one buffer pool is no longer necessary.
innodb_commit_concurrency	No need for thread throttling any more.
innodb_concurrency_tickets	No need for thread throttling any more.
innodb_log_files_in_group	Redo log was unnecessarily split into multiple files. Limited to 1 from MariaDB 10.5.
innodb_log_optimize_ddl	Prohibited optimizations.
innodb_page_cleaners	Having more than one page cleaner task no longer necessary.
innodb_replication_delay	No need for thread throttling any more.
innodb_scrub_log	Never really worked as intended, redo log format is being redone.
innodb_scrub_log_speed	Never really worked as intended, redo log format is being redone.
innodb_thread_concurrency	No need for thread throttling any more.
innodb_thread_sleep_delay	No need for thread throttling any more.
innodb_undo_logs	It always makes sense to use the maximum number of rollback segments.
large_page_size	Unused since multiple page size support was added.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.5:

- The S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- ColumnStore columnar storage engine.
- See also System Variables Added in MariaDB 10.5.

Upgrading from MariaDB 10.3 to MariaDB 10.4

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.4. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mysql_upgrade.

- `mysql_upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.3 and 10.4

On most servers upgrading from 10.3 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default value	New default value
slave_transaction_retry_errors	1213,1205	1158,1159,1160,1161,1205,1213,1429,2013,12701
wsrep_debug	OFF	NONE
wsrep_load_data_splitting	ON	OFF

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason

Authentication and TLS

- See Authentication from MariaDB 10.4 for an overview of the changes.
- The unix_socket authentication plugin is now default on Unix-like systems.
- TLSv1.0 is disabled by default in MariaDB 10.4. See tls_version and TLS Protocol Versions.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.4:

- Galera has been upgraded from Galera 3 to Galera 4.
- System-versioning extended with support for application-time periods.
- User password expiry
- Account Locking
- See also System Variables Added in MariaDB 10.4.

See Also

- The features in MariaDB 10.4
- Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster
- Upgrading from MariaDB 10.2 to MariaDB 10.3
- Upgrading from MariaDB 10.1 to MariaDB 10.2
- Upgrading from MariaDB 10.0 to MariaDB 10.1

This page is licensed: CC BY-SA / Gnu FDL

Upgrading from MariaDB 10.2 to MariaDB 10.3

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.3. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Stop MariaDB. The server should be cleanly shut down, with no incomplete transactions remaining. innodb_fast_shutdown must be set to `0` or `1` and innodb_force_recovery must be less than `3`.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mysql_upgrade.

- `mysql_upgrade` does two things:
  1. Ensures that the system tables in the `[mysq](#pg-reference-system-tables-the-mysql-database-tables-readme-35e9dbf3) l` database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.2 and 10.3

On most servers upgrading from 10.2 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default value	New default value
innodb_flush_method	(empty)	fsync
innodb_spin_wait_delay	6	4
performance_schema_max_stage_classes	150	160
plugin_maturity	unknown	One less than the server maturity

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_buffer_pool_populate	Used in XtraDB-only
innodb_cleaner_lsn_age_factor	Used in XtraDB-only
innodb_corrupt_table_action	Used in XtraDB-only
innodb_empty_free_list_algorithm	Used in XtraDB-only
innodb_fake_changes	Used in XtraDB-only
innodb_file_format	The InnoDB file format is now Barracuda, and the old Antelope file format is no longer supported.
innodb_file_format_check	No longer necessary as the Antelope InnoDB file format is no longer supported.
innodb_file_format_max	No longer necessary as the Antelope InnoDB file format is no longer supported.

Option	Reason
innodb_foreground_preflush	Used in XtraDB-only
innodb_instrument_semaphores	
innodb_kill_idle_transaction	Used in XtraDB-only
innodb_large_prefix	Large index key prefixes were made default from MariaDB 10.2, and limiting tables to small prefixes is no longer permitted in MariaDB 10.3.
innodb_locking_fake_changes	Used in XtraDB-only
innodb_log_arch_dir	Used in XtraDB-only
innodb_log_arch_expire_sec	Used in XtraDB-only
innodb_log_archive	Used in XtraDB-only
innodb_log_block_size	Used in XtraDB-only
innodb_log_checksum_algorithm	Translated to innodb_log_checksums (NONE to OFF, everything else to ON); only existed to allow easier upgrade from earlier XtraDB versions.
innodb_mtflush_threads	Replaced by the innodb_page_cleaners system variable.
innodb_sched_priority_cleaner	Used in XtraDB-only
innodb_show_locks_held	Used in XtraDB-only
innodb_show_verbose_locks	Used in XtraDB-only
innodb_support_xa	XA transactions are always supported.
innodb_use_fallocate	
innodb_use_global_flush_log_at_trx_commit	Used in XtraDB-only
innodb_use_mtflush	Replaced by the innodb_page_cleaners system variable.
innodb_use_stacktrace	Used in XtraDB-only
innodb_use_trim	

Reserved Words

- New reserved words: EXCEPT and INTERSECT. These can no longer be used as identifiers without being quoted.

SQL_MODE=ORACLE

- MariaDB 10.3 has introduced major new Oracle compatibility features. If you upgrade and are using this setting, please check the changes carefully.

Functions

- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- Functions that used to only return 64-bit now can return 32-bit results (MDEV-12619). This could cause incompatibilities with strongly-typed clients.

mysqldump

- mysqldump in MariaDB 10.3 includes logic to cater for the mysql.transaction_registry table. `mysqldump` from an earlier MariaDB release cannot be used on MariaDB 10.3 and beyond.

MariaDB Backup and Percona XtraBackup

- Percona XtraBackup is not compatible with MariaDB 10.3. Installations currently using XtraBackup should upgrade to MariaDB Backup before upgrading to MariaDB 10.3.

Privileges

- If a user has the SUPER privilege but not the `DELETE HISTORY` privilege, running mysql_upgrade will grant `DELETE HISTORY` as well.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.3:

- System-versioned tables
- Sequences
- See also System Variables Added in MariaDB 10.3.

See Also

- The features in MariaDB 10.3
- Upgrading from MariaDB 10.2 to MariaDB 10.3 with Galera Cluster
- Upgrading from MariaDB 10.1 to MariaDB 10.2
- Upgrading from MariaDB 10.0 to MariaDB 10.1

This page is licensed: CC BY-SA / Gnu FDL

Upgrading from MariaDB 10.1 to MariaDB 10.2

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend mariadb-backup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.2. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Set innodb_fast_shutdown to `0`. It can be changed dynamically with SET GLOBAL. For example:`SET GLOBAL innodb_fast_shutdown=0;`

- This step is not necessary when upgrading to MariaDB 10.2.5 or later. Omitting it can make the upgrade process far faster. See MDEV-12289 for more information.

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mysql_upgrade.

- `mysql_upgrade` does two things:
  1. Ensures that the system tables in the `[mysq](#pg-reference-system-tables-the-mysql-database-tables-readme-35e9dbf3) l` database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.1 and 10.2

On most servers upgrading from 10.1 should be painless. However, there are some things that have changed which could affect an upgrade:

InnoDB Instead of XtraDB

MariaDB 10.2 uses InnoDB as the default storage engine, rather than XtraDB, used in MariaDB 10.1 and before. See Why does MariaDB 10.2 use InnoDB instead of XtraDB? In most cases this should have minimal effect as the latest InnoDB has incorporated most of the improvements made in earlier versions of XtraDB. Note that certain XtraDB system variables are now ignored (although they still exist so as to permit easy upgrading).

Options That Have Changed Default Values

In particular, take note of the changes to innodb_strict_mode, sql_mode, binlog_format, binlog_checksum and innodb_checksum_algorithm.

Option	Old default value	New default value
aria_recover(_options)	NORMAL	BACKUP, QUICK
binlog_annotate_row_events	OFF	ON
binlog_checksum	NONE	CRC32
binlog_format	STATEMENT	MIXED
group_concat_max_len	1024	1048576
innodb_autoinc_lock_mode	1	2

Option	Old default value	New default value
innodb_buffer_pool_dump_at_shutdown	OFF	ON
innodb_buffer_pool_dump_pct	100	25
innodb_buffer_pool_instances	8	Varies
innodb_buffer_pool_load_at_startup	OFF	ON
innodb_checksum_algorithm	innodb	crc32
innodb_file_format	Antelope	Barracuda
innodb_large_prefix	OFF	ON
innodb_lock_schedule_algorithm	VATS	FCFS
innodb_log_compressed_pages	OFF	ON
innodb_max_dirty_pages_pct_lwm	0.001000	0
innodb_max_undo_log_size	1073741824	10485760
innodb_purge_threads	1	4
innodb_strict_mode	OFF	ON
innodb_undo_directory	.	NULL
innodb_use_atomic_writes	OFF	ON
innodb_use_trim	OFF	ON
lock_wait_timeout	31536000	86400
log_slow_admin_statements	OFF	ON
log_slow_slave_statements	OFF	ON
log_warnings	1	2
max_allowed_packet	4M	16M
max_long_data_size	4M	16M
myisam_recover_options	NORMAL	BACKUP, QUICK
optimizer_switch	See Optimizer Switch for details.	
replicate_annotate_row_events	OFF	ON
server_id	0	1
slave_net_timeout	3600	60
sql_mode	NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION
thread_cache_size	0	Auto

Option	Old default value	New default value
thread_pool_max_threads	1000	65536
thread_stack	295936	299008

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
aria_recover	Renamed to aria_recover_options to match myisam_recover_options.
innodb_additional_mem_pool_size	Deprecated in MariaDB 10.0.
innodb_api_bk_commit_interval	Memcache never implemented in MariaDB.
innodb_api_disable_rowlock	Memcache never implemented in MariaDB.
innodb_api_enable_binlog	Memcache never implemented in MariaDB.
innodb_api_enable_mdl	Memcache never implemented in MariaDB.
[	innodb_api_trx_level](../../../../reference/storage-engines/innodb/innodb-system-variables.md)
innodb_use_sys_malloc	Deprecated in MariaDB 10.0.

Reserved Words

New reserved words: OVER, RECURSIVE and ROWS. These can no longer be used as identifiers without being quoted.

TokuDB

TokuDB has been split into a separate package, mariadb-plugin-tokudb.

Replication

Replication from legacy MySQL servers may require setting binlog_checksum to NONE.

SQL Mode

SQL_MODE has been changed; in particular, NOT NULL fields with no default will no longer fall back to a dummy value for inserts which do not specify a value for that field.

Auto_increment

Auto_increment columns are no longer permitted in CHECK constraints, DEFAULT value expressions and virtual columns. They were permitted in earlier versions, but did not work correctly.

TLS

Starting with MariaDB 10.2, when the user specifies the `--ssl` option with a client or utility, the client or utility will not verify the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option to the client or utility. For more information, see the list of options for the mysql client.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.2:

- Window Functions
- mysqlbinlog now supports continuous binary log backups

- Recursive Common Table Expressions
- JSON functions
- See also System Variables Added in MariaDB 10.2.

Upgrading from MariaDB 10.0 to MariaDB 10.1

What You Need to Know

There are no changes in table or index formats between MariaDB 10.0 and MariaDB 10.1, so on most servers the upgrade should be painless.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading from MariaDB Galera Clusterinstead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Percona XtraBackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.1. For example,

- On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.

1. Set innodb_fast_shutdown to `0`. It can be changed dynamically with SET GLOBAL. For example:`SET GLOBAL innodb_fast_shutdown=0;`
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, execute the following: `sudo apt-get remove mariadb-server`
- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following: `sudo yum remove MariaDB-server`
- On SLES, OpenSUSE, and other similar Linux distributions, execute the following: `sudo zypper remove MariaDB-server`

1. Install the new version of MariaDB.

- On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.

- On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
- On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.

1. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
2. Start MariaDB.
3. Run mysql_upgrade.

- `mysql_upgrade` does two things:
  1. Ensures that the system tables in the `[mysq](#pg-reference-system-tables-the-mysql-database-tables-readme-35e9dbf3) l` database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.0 and 10.1

As mentioned previously, on most servers upgrading from 10.0 should be painless.
However, there are some things that have changed which could affect an upgrade:

Storage Engines

- The ARCHIVE storage engine is no longer enabled by default, and the plugin needs to be specifically enabled.
- The BLACKHOLE storage engine is no longer enabled by default, and the plugin needs to be specifically enabled.

Replication

- MariaDB 10.1 introduces new, standards-compliant behavior for dealing with primary keys over nullable columns. In certain edge cases this could cause replication issues when replicating from a MariaDB 10.0 master to a MariaDB 10.1 slave using statement-based replication. See MDEV-12248.

Options That Have Changed Default Values

Most of the following options have increased in value to give better performance.

Option	Old default value	New default value
innodb_log_compressed_pages	ON	OFF
join_buffer_size	128K	256K
max_allowed_packet	1M	4M
query_alloc_block_size	8192	16384
query_cache_size	0	1M
query_cache_type	ON	OFF
sync_master_info	0	10000
sync_relay_log	0	10000
sync_relay_log_info	0	10000
query_prealloc_size	8192	24576
secure_auth	OFF	ON
sql_log_bin		No longer affects replication of events in a Galera cluster.
sql_mode	empty	NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION
table_open_cache	400	2000

Option	Old default value	New default value
thread_pool_max_threads	500	1000

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your config files:

Option	Reason
rpl_recovery_rank	Unused in 10.0

Other Issues

Note that explicit or implicit casts from MAX(string) to INT, DOUBLE or DECIMAL now produce warnings (MDEV-8852).

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.1:

- Galera Cluster is now included by default.
- Encryption
- InnoDB/XtraDB Page Compression

Notes

- Upgrading from MariaDB 5.5 to MariaDB 10.0

This page is licensed: CC BY-SA / Gnu FDL

Upgrading from MariaDB 5.3 to MariaDB 5.5

What you need to know

There are no changes in table or index formats between MariaDB 5.3 and MariaDB 5.5, so on most servers the upgrade should be painless.

How to upgrade

The suggested upgrade procedure is:

1. For Windows, see Upgrading MariaDB on Windows instead.
2. Shutdown MariaDB 5.3
3. Take a backup (this is the perfect time to take a backup of your databases)
4. Uninstall MariaDB 5.3
5. Install MariaDB 5.5 [1]
6. Run mysql_upgrade

- Ubuntu and Debian packages do this automatically when they are installed; Red Hat, CentOS, and Fedora packages do not
- `mysql_upgrade` does two things:
  1. Upgrades the permission tables in the `mysql` database with some new fields

2. Does a very quick check of all tables and marks them as compatible with MariaDB 5.5

- In most cases this should be a fast operation (depending of course on the number of tables)

1. Add new options to my.cnf to enable features

- If you change `my.cnf` then you need to restart `mysqld`

Incompatible changes between 5.3 and 5.5

As mentioned previously, on most servers upgrading from 5.5 should be painless.
However, there are some things that have changed which could affect an upgrade:

XtraDB options that have changed default values

Option	Old value	New value
innodb_change_buffering	inserts	all
innodb_flush_neighbor_pages	1	area

Options that have been removed or renamed

Percona, the provider of XtraDB, does not provide all earlier XtraDB features in the 5.5 code base. Because of that, MariaDB 5.5 can't provide them either. The following options are not supported by XtraDB 5.5. If you are using them in any of your my.cnf files, you should remove them before upgrading to 5.5.

- innodb_adaptive_checkpoint; Use innodb_adaptive_flushing_method instead.
- innodb_auto_lru_dump; Use innodb_buffer_pool_restore_at_startup instead (and innodb_buffer_pool_load_at_startup in MariaDB 10.0).
- innodb_blocking_lru_restore; Use innodb_blocking_buffer_pool_restore instead.
- innodb_enable_unsafe_group_commit
- innodb_expand_import; Use innodb_import_table_from_xtrabackup instead.
- innodb_extra_rsegments; Use innodb_rollback_segments instead.
- innodb_extra_undoslots
- innodb_fast_recovery
- innodb_flush_log_at_trx_commit_session
- innodb_overwrite_relay_log_info; Use innodb_recovery_update_relay_log instead.
- innodb_pass_corrupt_table; Use innodb_corrupt_table_action instead.
- innodb_use_purge_thread

Notes

1. ↑ If using a MariaDB `apt` or `yum` repository, it is often enough to replace instances of '5.3' with '5.5' and then run an update/upgrade. For example, in Ubuntu/Debian update the MariaDB `sources.list` entry from something that looks similar to this:

```
deb http://ftp.osuosl.org/pub/mariadb/repo/5.3/ubuntu trusty main
```

To something like this:

```
deb http://ftp.osuosl.org/pub/mariadb/repo/5.5/ubuntu trusty main
```

And then run

```
apt-get update && apt-get upgrade
```

And in Red Hat, CentOS, and Fedora, change the `baseurl` line from something that looks like this:

```
baseurl = http://yum.mariadb.org/5.3/centos6-amd64
```

To something that looks like this:

```
baseurl = http://yum.mariadb.org/5.5/centos6-amd64
```

And then run

```
yum update
```

General Upgrade Information

While specific guides exist for upgrading between individual versions, it is important to understand the general policies regarding skipping versions and upgrading clusters.

Direct Upgrade Policy

Historically, upgrading MariaDB Community Server required stepping through each major version individually. However, for modern versions, **you can upgrade directly from your current version to the latest target version** in most scenarios.

- **Skip Intermediate Versions:** Skipping intermediate major or LTS versions is fully supported and tested for standalone servers.
- **Check Incompatible Changes:** Even when skipping versions, you **must** review the “Incompatible Changes” section for *every* major version between your current version and your target version. This ensures your application does not rely on functionality, configuration, or reserved keywords that have been deprecated or modified in the interim.
- **Troubleshooting:** If you are unsure about your application’s compatibility, upgrading one major/LTS version at a time is recommended. This incremental approach makes it easier to isolate the specific version that introduces a breaking change or application issue.

Galera Cluster Upgrades

The upgrade strategy for Galera Clusters differs depending on whether you require zero downtime.

Rolling Upgrades

If you are performing a rolling upgrade to keep the cluster online:

- You **must upgrade one major/LTS version at a time**.
- Due to the complexity of intra-node communication, skipping versions during a rolling upgrade is not supported.
- This process requires multiple upgrade cycles, but the cluster remains available to applications throughout.

Full Cluster Shutdown

If you can schedule downtime for the entire cluster:

- You may shut down all nodes, upgrade them all to the target version, and then bring the cluster back up.

- In this scenario, a **direct upgrade** (skipping intermediate versions) is supported, similar to a standalone server.

Upgrade to MariaDB Enterprise Server 11.8

Overview

These instructions detail the **upgrade** from a previous version of **MariaDB Enterprise Server** to **MariaDB Enterprise Server 11.8** on a range of supported Operating Systems.

When MariaDB Enterprise Server is upgraded, the old version needs to be uninstalled, and the new version needs to be installed.

See What's New in MariaDB Enterprise Server 11.8.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup before upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup. On MariaDB Enterprise Server 11.8 and later:

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the backup operation.

2. The backup must be prepared. On the MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-backup --prepare \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Audit Plugin Considerations

If you have the MariaDB Audit Plugin installed and are upgrading from MariaDB Enterprise Server 10.2 or 10.3, the audit plugin should be removed prior to the upgrade to prevent conflicts with the MariaDB Enterprise Audit Plugin, which MariaDB Enterprise Audit Plugin that is present in MariaDB Enterprise Server 10.4 or later. It can be removed by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

And if you load the plugin in a configuration file using the `plugin\_load\_add` option, then the option should also be removed. The MariaDB Enterprise Audit Plugin will automatically be installed after installing MariaDB Enterprise Server 10.4 or later.

Uninstall the Old Version

When upgrading to a new major release of MariaDB Enterprise Server, it is necessary to remove the existing installation of MariaDB Enterprise Server before installing the new version of MariaDB Enterprise Server. Otherwise, the package manager will refuse to install the new version of MariaDB Enterprise Server.

Stop the MariaDB Server Process

Before the old version can be uninstalled, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to 1:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

```
XA RECOVER;
```

Commit or roll back any open XA transactions before stopping the node for upgrade.

3. Stop the server process: For distributions that use `systemd` (most supported OSes), you can manage the server process using the `systemctl` command:

```
sudo systemctl stop mariadb
```

Uninstall via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo yum remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications:

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called `galera-enterprise-4`:

```
sudo yum remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Uninstall via APT (Debian, Ubuntu)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo apt-get remove "mariadb-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo apt remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
apt list --installed | grep -i -E "mariadb|galera"
```

Uninstall via ZYpp (SLES)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo zypper remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo zypper remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure YUM package repositories:

```
sudo yum install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo yum install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the APT package repository. Installable versions of MariaDB Enterprise Server are `11.8 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure APT package repositories:

```
sudo apt install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

```
sudo apt update
```

3. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup galera-enterprise-4
```

4. Installation of additional packages may be required for some plugins. Configure MariaDB. Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the ZYpp package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure ZYpp package repositories:

```
sudo zypper install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo zypper install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Configuration

For platforms that use YUM or ZYpp as a package manager: MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back.

For example, to move `server.cnf` back in place:

```
sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to `start, stop, restart, enable/disable` on boot, and check the status of the Server using the operating system's default process management system.

For distributions that use `systemd`, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`

Operation	Command
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called `mariadb-upgrade` in MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account. MariaDB Client is called `mariadb` (ES 10.4 and later):

```
sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 9
Server version: 11.8.2-0-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL VARIABLES LIKE 'version';
```

```
+---------------+----------------------------+
| Variable_name | Value                      |
+---------------+----------------------------+
| version       | 11.8.3-1-MariaDB-Enterprise |
+---------------+----------------------------+
```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+----------------------------+
| VERSION()                  |
+----------------------------+
| 11.8.3-1-MariaDB-Enterprise |
+----------------------------+
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

Upgrade MariaDB Enterprise Server from 11.8.X to 11.8.Y

These instructions detail a **minor release upgrade** with **MariaDB Enterprise Server 11.8** on a range of supported Operating Systems.

A minor release upgrade is a change from an earlier release of MariaDB Enterprise Server 11.8 to a later release in the same release series.

For example, it would be a minor release upgrade to upgrade from MariaDB Enterprise Server 11.8.2-0 to MariaDB Enterprise Server 11.8.3-1.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup before upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup:

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the backup operation.

2. The backup must be prepared:

```
sudo mariadb-backup --prepare \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Stop the MariaDB Server Process

Before the new version can be installed, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to 1:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

```
XA RECOVER;
```

Commit or roll back any open XA transactions before stopping the node for upgrade.

3. Stop the server process. For distributions that use `systemd` (most supported OSes), you can manage the server process using the `systemctl` command:

```
sudo systemctl stop mariadb
```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

For a minor release upgrade, the existing MariaDB Enterprise Server packages do not need to be uninstalled. The packages are updated in place.

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3`. Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure YUM package repositories:

```
sudo yum install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

3. Update MariaDB Enterprise Server and package dependencies:

```
sudo yum update "MariaDB-*" "galera*"
```

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the APT package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3`. Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure APT package repositories:

```
sudo apt install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

Note:

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

```
sudo apt update
```

3. Update MariaDB Enterprise Server and package dependencies:

```
sudo apt install --only-upgrade "mariadb-*" "galera*"
```

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the ZYpp package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3`. Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure ZYpp package repositories:

```
sudo zypper install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

Note:

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

3. Update MariaDB Enterprise Server and package dependencies:

```
sudo zypper update "MariaDB-*" "galera*"
```

Configuration

For platforms that use YUM or ZYpp as a package manager: MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back.

For example, to move `server.cnf` back in place:

```
sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system's default process management system.

For distributions that use `systemd`, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called `mariadb-upgrade`:

```
sudo mariadb-upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account. MariaDB Client is called `mariadb`:

```
sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 9
Server version: 11.8.3-1-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL VARIABLES LIKE 'version';
```

```
+---------------+----------------------------+
| Variable_name | Value                      |
+---------------+----------------------------+
| version       | 11.8.3-1-MariaDB-Enterprise |
+---------------+----------------------------+
```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+----------------------------+
| VERSION()                  |
+----------------------------+
| 11.8.3-1-MariaDB-Enterprise |
+----------------------------+
```

Upgrading from MariaDB Enterprise Server 10.6 to 11.8

This guide outlines the process for performing a major version upgrade from MariaDB Enterprise Server (ES) 10.6 directly to MariaDB Enterprise Server 11.8.

> **Note:**
>
> This guide assumes you are running on a variant of Linux that uses `systemd` to manage services (such as RHEL, CentOS, AlmaLinux, Rocky Linux, Debian, Ubuntu, or SLES).

> **Note:**
>
> Running MariaDB Enterprise Server in a **Galera Cluster**? See Upgrading from MariaDB Enterprise Server 10.6 to 11.8 with Galera Cluster for the cluster-specific procedure (packages, shutdown order, and bootstrapping). The configuration changes below apply to every node.

Prerequisites

Before beginning the upgrade, ensure these precautionary measures and environment checks are completed to protect your data.

Data Backup and Integrity

- Perform a Full Backup: Use `mariadb-backup` to create a complete copy of your current data.

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_10.6_to_11.8
```

- Prepare the Backup: Consolidate the backup files so they are ready for immediate restoration if required.

```
sudo mariadb-backup --prepare --target-dir=/data/backup/preupgrade_10.6_to_11.8
```

- Verify Recoverability: Test your backup by restoring it to a non-production environment before proceeding.

Service and Plugin Preparation

- Audit Plugin Transition: If you currently use the MariaDB 10.6 Audit Plugin (`server_audit.so`), it is recommended to transition to the MariaDB Enterprise Audit Plugin during this upgrade. If you maintain the Community version, ensure your configuration explicitly loads it to avoid conflicts.
- Commit or Roll Back XA Transactions: Run XA RECOVER; to identify any external XA transactions in a prepared state; these must be finalized before the service is stopped.

Compatibility & Legacy Support

This ensures the team can maintain 10.6 behavior for applications that aren't ready for the new defaults.

- Handling Non-Default Character Sets: If your 10.6 instance uses `latin1` or `utf8mb3` , do not switch to `utf8mb4` immediately. You must explicitly define your existing character set in the new `my.cnf` to override the 11.8 defaults.
- The `OLD_MODE` Tip: Set `old_mode = UTF8_IS_UTF8MB3` in your configuration; this ensures that `utf8` remains an alias for the legacy 3-byte character set instead of the new 4-byte standard.
- Maintaining SSL Compatibility: Version 11.4+ enables "Zero-configuration TLS" by default. If your application does not support SSL, set `require_secure_transport = OFF` in the `[mariadb]` section of your `my.cnf` to prevent connection refusals.

Environment Compatibility

- Engineering Policy: Verify your operating system version is still supported for the 11.8 series by checking the MariaDB Engineering Policies.
- Customer Token: Have your Customer Download Token ready for the repository configuration step.

The Upgrade Procedure

> **Step 1**
>
> **Perform a Controlled Shutdown of 10.6**
>
> 1. Initiate Fast Shutdown to ensure the InnoDB engine closes cleanly.
>
> ```
> SET GLOBAL innodb_fast_shutdown = 1;
> ```
>
> 2. Stop the Service `mariadb` .
>
> ```
> sudo systemctl stop mariadb
> ```

Step 2

Purge Legacy 10.6 Packages

Remove the old version to prevent package manager conflicts before installing 11.8.

- YUM (RHEL/CentOS/Alma/Rocky): `sudo yum remove "MariaDB-*" galera-enterprise-4`
- APT (Debian/Ubuntu): `sudo apt-get remove "mariadb-*" galera-enterprise-4`
- ZYpp (SLES): `sudo zypper remove "MariaDB-*" galera-enterprise-4`

Step 3

Switch to 11.8 Enterprise Repositories

Download and run the setup script, specifying version `11.8`.

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
chmod +x mariadb_es_repo_setup
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply --mariadb-server-version="11.8"
```

Step 4

Install the 11.8 Release Series

The repository setup only configures the source; you must explicitly install the new binaries.

- YUM: `sudo yum install MariaDB-server MariaDB-backup`
- APT: `sudo apt update && sudo apt install mariadb-server mariadb-backup`
- ZYpp: `sudo zypper install MariaDB-server MariaDB-backup`

Step 5

Implement Version-Specific Configuration Changes

> **Note:**
>
> Do not apply 11.8-specific variables while the 10.6 service is active. During the package swap, update `my.cnf` to adopt the 11.8 defaults for the Optimizer Cost Model. These variables replace legacy hardcoded logic and are essential for the new engine's performance.

- Scrub: Remove legacy 10.6 variables (`old_alter_table`, etc.).
- Adopt: Add the new Optimizer Cost Model variables using their 11.8 defaults.
- Stabilize: Set `new_mode = ""` to keep query planning closer to 10.6 and prevent unpredictable execution plan changes on Day 1. `new_mode` is a `SET` variable and does not accept a literal `OFF` value — setting `OFF` aborts startup (including during Galera/wsrep recovery). Note: `""` is not the 11.8 default (the default is `FIX_DISK_TMPTABLE_COSTS`), so this is a deliberate opt-out.

> **Tip:**
>
> **Recommended `my.cnf` for Version 11.8 section**

```
[mariadb]
# --- CHARACTER SETS & COLLATIONS ---
# utf8mb4 is the modern default; UCA 14.0.0 is ID #2304
character-set-server  = utf8mb4
collation-server      = utf8mb4_uca1400_ai_ci
# Use old_mode if your app requires 3-byte utf8 aliases
old_mode              = UTF8_IS_UTF8MB3

# --- OPTIMIZER COST MODEL (CRITICAL #) ---
# Adopting 11.8 defaults replaces legacy hardcoded logic.
# Set new_mode empty to keep 10.6-like query planning ("" is not the default; the default is
FIX_DISK_TMPTABLE_COSTS).
new_mode                      = ""
optimizer_disk_read_cost      = 10.24
optimizer_disk_read_ratio     = 0.02
optimizer_extra_pruning_depth = 8
optimizer_index_block_copy_cost = 0.0356
optimizer_key_compare_cost    = 0.011361
optimizer_key_copy_cost       = 0.015685
optimizer_key_lookup_cost     = 0.435777
optimizer_key_next_find_cost  = 0.082347
optimizer_rowid_compare_cost  = 0.002653
optimizer_rowid_copy_cost     = 0.002653
optimizer_row_copy_cost       = 0.060866
optimizer_row_lookup_cost     = 0.130839
optimizer_row_next_find_cost  = 0.045916
optimizer_scan_setup_cost     = 10
optimizer_where_cost          = 0.032

# --- INNODB STORAGE ENGINE ---
innodb_flush_method      = O_DIRECT
innodb_undo_log_truncate = ON
innodb_purge_batch_size  = 1000

# --- REPLICATION SAFETY NET ---
# REQUIRED for failing back to an existing 10.6 node.
# Fixes "Character set #2304" errors on legacy replicas.
character_set_collations = ''
binlog_alter_two_phase   = 1

# --- COMPLIANCE & CLEANUP ---
transaction_isolation    = REPEATABLE-READ
transaction_read_only    = OFF
```

> **Step 6**
>
> **Bring the Service Online and Finalize Data**
>
> 1. Start the New Service: `sudo systemctl start mariadb`.
> 2. Execute the Data Upgrade Utility: This corrects system table structures and marks data files as compatible with version 11.8.
>
>    ```
>    sudo mariadb-upgrade
>    ```

Incompatible and Significant Changes

The following variables from version 10.6 have been removed, renamed, or deprecated in the 11.8 release series.

New Variables Added in 11.8

> **Note:**
>
> Once the 11.8 binaries are installed, update your `my.cnf` to define these new variables.

Optimizer Cost Model Variables

> **Warning:**
>
> **Handle with care**
>
> Because the 11.8 engine uses a completely new “weighting” system designed for modern storage (SSDs), altering these variables without extensive benchmarks can lead to severe performance degradation or inefficient query execution plans. It is strongly recommended to keep these at their defaults upon upgradation unless you are performing expert-level performance tuning.

These variables define the weights of the new optimizer. If query execution plans change after the upgrade, these parameters are the primary audit points and represent the optimizer cost model.

Variable Name	11.8 Default	Note
`NEW_MODE`	`FIX_DISK_TMPTABLE_COSTS`	Recommended: set to `""` (empty) for 10.6-like planning. `new_mode` is a `SET` variable and does not accept a literal `OFF` value (`OFF` aborts startup).
`OPTIMIZER_DISK_READ_COST`	`10.24`	**Optimizer Plan Consistency:** Row-based replication (RBR) remains unaffected by these changes. However, because the 11.8 Primary uses the new cost model while legacy 10.6 nodes use hardcoded logic, query execution plans may differ significantly between the Master and Slave.
`OPTIMIZER_DISK_READ_RATIO`	`0.02`	
`OPTIMIZER_EXTRA_PRUNING_DEPTH`	`8`	

Variable Name	11.8 Default	Note
OPTIMIZER_INDEX_BLOCK_COPY_COST	0.0356	
OPTIMIZER_KEY_COMPARE_COST	0.011361	
OPTIMIZER_KEY_COPY_COST	0.015685	
OPTIMIZER_KEY_LOOKUP_COST	0.435777	
OPTIMIZER_KEY_NEXT_FIND_COST	0.082347	
OPTIMIZER_ROWID_COMPARE_COST	0.002653	
OPTIMIZER_ROWID_COPY_COST	0.002653	
OPTIMIZER_ROW_COPY_COST	0.060866	
OPTIMIZER_ROW_LOOKUP_COST	0.130839	
OPTIMIZER_ROW_NEXT_FIND_COST	0.045916	
OPTIMIZER_SCAN_SETUP_COST	10	
OPTIMIZER_WHERE_COST	0.032	

InnoDB Variables

InnoDB used complex buffering (like the “Change Buffer”) to delay writes because hard drives were slow at random I/O. In version 11.8, these legacy layers are being stripped back. The following InnoDB System Variables allow MariaDB to communicate more directly with modern SSD/NVMe storage, reducing the “middleman” overhead of the Operating System’s cache.

Variable Name	11.8 Default
INNODB_ADAPTIVE_HASH_INDEX_CELLS ^	34679
INNODB_ALTER_COPY_BULK #	ON
INNODB_BUFFER_POOL_SIZE_AUTO_MIN	134217728
INNODB_BUFFER_POOL_SIZE_MAX	134217728
INNODB_DATA_FILE_BUFFERING	OFF
INNODB_DATA_FILE_WRITE_THROUGH	OFF
INNODB_LINUX_AIO	auto
INNODB_LOG_CHECKPOINT_NOW	OFF
INNODB_LOG_FILE_BUFFERING	OFF
INNODB_LOG_FILE_MMAP	OFF
INNODB_LOG_FILE_WRITE_THROUGH	OFF
INNODB_LOG_SPIN_WAIT_DELAY	0
INNODB_TRUNCATE_TEMPORARY_TABLESPACE_NOW	OFF

Replication & Binlog Variables

As clusters grow, managing the Global Transaction ID (GTID) list becomes a performance bottleneck. 11.8 introduces “GTID Indexing,” which treats the replication and log more like a database table, allowing for near-instant lookups when a replica reconnects. See Replication and Binary Logging Variables to learn more about the variables.

Variable Name	11.8 Default	Note
`BINLOG_ALTER_TWO_PHASE` #	`OFF`	
`BINLOG_DO_DB`	`(None)`	
`BINLOG_GTID_INDEX` #	`ON`	
`BINLOG_GTID_INDEX_PAGE_SIZE` #	`4096`	
`BINLOG_GTID_INDEX_SPAN_MIN` #	`65536`	
`BINLOG_IGNORE_DB`	`(None)`	
`BINLOG_LARGE_COMMIT_THRESHOLD`	`134217728`	
`BINLOG_LEGACY_EVENT_POS` #	`OFF`	
`BINLOG_ROW_EVENT_MAX_SIZE` #	`8192`	Packet Safety: Ensure this value on the 11.8 Primary is strictly lower than the `MAX_ALLOWED_PACKET` setting on your 10.6 Replicas. If an 11.8 row event exceeds the legacy replica's packet limit, replication will fail with a "Packet too large on slave" error.
`BINLOG_SPACE_LIMIT`	`0`	
`REPLICATE_REWRITE_DB` #	`(None)`	
`SLAVE_ABORT_BLOCKING_TIMEOUT`	`31536000`	
`SLAVE_CONNECTIONS_NEEDED_FOR_PURGE` #	`1`	**Binary Log Purge Safety:** The default value is `1`. If your topology requires that binary logs be retained until they are acknowledged by multiple replicas, increase this value to prevent the primary from purging logs before all critical slaves have synchronized the data.
`SLAVE_MAX_STATEMENT_TIME`	`0`	

Advanced Logging Variables

Slow logging was often a “blunt instrument” that could either miss critical spikes or flood the disk with useless data. Version 11.8 introduces granular filters. You can now tell the engine to ignore queries that touch many rows but are still fast, or to ensure that queries exceeding a specific “emergency” duration are always captured, regardless of other filters. See Server System Variables to learn more about the following variables

Variable Name	11.8 Default
`LOG_SLOW_ALWAYS_QUERY_TIME`	`31536000`
`LOG_SLOW_MIN_EXAMINED_ROW_LIMIT`	`0`
`LOG_SLOW_QUERY`	`OFF`
`LOG_SLOW_QUERY_FILE`	`(Host Specific)`
`LOG_SLOW_QUERY_TIME`	`10`

Security & Authentication Variables

MariaDB 11.8 shifts toward modern cryptographic standards. This includes better handling of User Defined Functions (UDFs) and a transition toward the caching_sha2_password plugin, which provides significantly stronger protection against “man-in-the-middle” and brute-force attacks compared to legacy authentication.

Variable Name	11.8 Default
`ALLOW_SUSPICIOUS_UDFS`	`OFF`
`SKIP_GRANT_TABLES` #	`OFF`

Resource Limits Variables

A single unoptimized query could theoretically consume all available disk space by creating a massive temporary table, crashing the entire operating system. Version 11.8 introduces “Safety Valves” that allow administrators to set hard limits on how much temporary space a single session or the entire server can use.

Variable Name	11.8 Default
`MAX_BINLOG_TOTAL_SIZE`	`0`
`MAX_TMP_SESSION_SPACE_USAGE`	`1099511627776` (1TB)
`MAX_TMP_TOTAL_SPACE_USAGE`	`1099511627776` (1TB)

Vector Search / MHNSW Variables

MariaDB 11.8 introduces a native Vector Search engine using the Metadata-HNSW (Hierarchical Navigable Small Worlds) algorithm. This allows the database to store and query “embeddings” (mathematical representations of text/images), enabling AI-powered semantic search directly within the SQL layer.

> **Note:**
>
> A feature entirely absent in MariaDB 10.6, MariaDB 11.8 introduced native Vector Search (MHNSW).
>
> - Primary Config: Use `MHNSW_DEFAULT_DISTANCE` to define semantic search logic (default: `euclidean`).
> - Compatibility Warning: Legacy 10.6 replicas cannot process vector data types or SQL functions; using them will break the replication link.

Variable Name	11.8 Default
`MHNSW_DEFAULT_DISTANCE` #	`euclidean`
`MHNSW_DEFAULT_M`	`6`

Variable Name	11.8 Default
`MHNSW_EF_SEARCH`	`20`
`MHNSW_MAX_CACHE_SIZE`	`16777216`

General Architecture Changes Variables

The final group of changes focuses on renaming legacy variables for industry compliance (SQL Standard) and adding features that improve how the database communicates with external tools, such as proxies or system-versioning audit logs.

Variable Name	11.8 Default	Note
`REDIRECT_URL` #	`(None)`	**Replication Redirection Safety:** The `REDIRECT_URL` variable allows the server to send redirection hints to proxies or clients. **Crucial**: Configure this carefully on replicas to ensure that internal slave-to-primary connections are not redirected, as accidental redirection of replication traffic will break the sync link.
`SYSTEM_VERSIONING_INSERT_HISTORY` #	`OFF`	**System Versioning & Binlog Replay** The default value for this variable is acceptable for standard operations. However, because MariaDB 11.8's `mariadb-binlog` utility explicitly prints this value in its output, replaying binary logs using the 11.8 version of the tool is not recommended during the transition period.
`BLOCK_ENCRYPTION_MODE` ^	`aes-128-ecb`	High; Block_encryption_mode default on 11.8 is fine, but we should be careful when calling AES_ENCRYPT and AES DECRYPT_FUNCTION as syntax is different in 10.6
`CHARACTER_SET_COLLATIONS` #	`utf8mb4=…`	Character_set_collations should be empty for 11.8 -> 10.6
`TRANSACTION_ISOLATION` #	`REPEATABLE-READ`	
`TRANSACTION_READ_ONLY` #	`OFF`	
`WSREP_ALLOWLIST`	`(None)`	
`WSREP_STATUS_FILE`	`(None)`	

Important:

#Handle them with extra care

These variables have the highest impact on system stability and performance; please review during your configuration updates.

Warning:

^Caution

These variables may impact system stability and performance; please review during your configuration updates.

Options to Remove, Rename, or Update in 11.8

Removed, Superseded or Renamed Options

During the maintenance window (after stopping 10.6 and before starting 11.8), you must scrub your `my.cnf` of all removed, superseded and renamed options.

Variable Name	10.6 Default	Technical Action / Replacement
`DATETIME_FORMAT` [2]	`%Y-%m-%d %H:%i:%s`	Scrub. 11.8 enforces standard internal format strings.
`DATE_FORMAT` [2]	`%Y-%m-%d`	Scrub. Enforced standard format.
`DEBUG_NO_THREAD_ALARM` [1]	`OFF`	Remove. Retired legacy debug code.
`INNODB_CHANGE_BUFFERING` [2]	`none`	Scrub. Logic replaced by SSD-optimized write paths.
`INNODB_CHANGE_BUFFER_MAX_SIZE` [1]	`25`	Remove. Buffer size is now managed internally by the engine.
`INNODB_DEFRAGMENT` [2]	`OFF`	Scrub. Manual defragmentation is no longer supported.
`INNODB_DEFRAGMENT_FILL_FACTOR` [2]	`0.9`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_FILL_FACTOR_N_RECS` [2]	`20`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_FREQUENCY` [2]	`40`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_N_PAGES` [2]	`7`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_STATS_ACCURACY` [2]	`0`	Scrub. Feature retired; logic is now internal.
`INNODB_VERSION` [1]	`10.6.26`	Remove. Versioning is consolidated in global server metadata.
`MAX_TMP_TABLES` [1]	`32`	Remove. Internal temp table management is now automated.
`OLD_ALTER_TABLE` [1]	`DEFAULT`	Remove. Superseded by `ALTER_ALGORITHM`.
`TIME_FORMAT` [2]	`%H:%i:%s`	Scrub. Enforced standard format.
`WSREP_CAUSAL_READS` [2]	`OFF`	Scrub. Superseded by `wsrep_sync_wait`.
`WSREP_LOAD_DATA_SPLITTING` [1]	`OFF`	Remove. Legacy Galera splitting logic retired.
`WSREP_REPLICATE_MYISAM` [1]	`OFF`	Remove. Galera no longer supports MyISAM replication.
`WSREP_STRICT_DDL` [1]	`OFF`	Remove. Replaced by `wsrep_mode=STRICT_REPLICATION`.

Important:

[1]Fatal Error

MariaDB 11.8 will abort startup if these legacy parameters are detected in the configuration file. These parameters MUST be removed prior to restart to prevent upgrade failure.

Example: `[ERROR] /usr/sbin/mariadbd: unknown variable 'MAX_TMP_TABLES=32'`

Warning:

[2]Warning:

MariaDB 11.8 will start but log a warning if these legacy parameters are detected in the configuration file. Scrub the file of these parameter during the upgrade to maintain configuration hygiene and ensure settings reflect active 11.8 features.

Warning Example: `[Warning] 'innodb-change-buffering' was removed. It does nothing now and exists only for compatibility with old my.cnf files.`

Options That Have Changed Default Values

> **Note:**
>
> For variables that have existed in both versions but have different defaults (e.g., `innodb_purge_batch_size`), the 11.8 engine will automatically apply the new value. If you require identical behavior to your 10.6 environment during the initial cutover, you must explicitly hardcode the 10.6 values into your new configuration file.

Options	10.6 Default	11.8 Default	Impact / Note
`character_set_server`	`latin1`	`utf8mb4`	Certified Change:Global default encoding shift.
`CHARACTER_SET_CLIENT`	`latin1`	`utf8mb4`	Modern standard for client connections.
`CHARACTER_SET_CONNECTION`	`latin1`	`utf8mb4`	Modern standard for session connections.
`CHARACTER_SET_DATABASE`	`latin1`	`utf8mb4`	Modern standard for database storage.
`CHARACTER_SET_RESULTS`	`latin1`	`utf8mb4`	Modern standard for query results.

Options	10.6 Default	11.8 Default	Impact / Note
`collation_server`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Transition to the modern Unicode collation standard.
`COLLATION_CONNECTION`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Update to modern Unicode Collation Algorithm (UCA).
`COLLATION_DATABASE`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Update to modern Unicode Collation Algorithm (UCA).

Options	10.6 Default	11.8 Default	Impact / Note
`EXPLICIT_DEFAULTS_FOR_TIMESTAMP`	`OFF`	`ON`	Impacts `NULL` handling in `TIMESTAMP` columns. Modify for reverse replication (11.8->10.6) to maintain same behavior on master and slave
`HAVE_SSL`	`DISABLED`	`YES`	SSL/TLS is now natively available and enabled by default.

Options	10.6 Default	11.8 Default	Impact / Note
`HISTOGRAM_TYPE`	(Empty)	`JSON_HB`	Optimizer now stores histogram stats in JSON format. Modify for reverse replication (11.8->10.6) to maintain same behavior on master and slave
`IGNORE_DB_DIRS`		#binlog_cache_files	
`INNODB_BUFFER_POOL_CHUNK_SIZE`	`134217728`	`0`	Set to `0` to enable automatic calculation.
`INNODB_LOG_WRITE_AHEAD_SIZE`	`8192`	`4096`	Optimized for modern storage block alignment.

Options	10.6 Default	11.8 Default	Impact / Note
`innodb_snapshot_isolation`	`OFF`	`ON`	Enabled by default for improved consistency.
`innodb_undo_tablespaces`	`0`	`3`	Enables online truncation of undo logs.
`optimizer_prune_level`	`1`	`2`	Red Flag: Primary audit point for plan changes.

Options	10.6 Default	11.8 Default	Impact / Note
OPTIMIZER_SWITCH	index_merge=on index_merge_union=on index_merge_sort_union=on index_merge_intersection=on index_merge_sort_intersection=off engine_condition_pushdown=off index_condition_pushdown=on derived_merge=on derived_with_keys=on firstmatch=on loosescan=onmaterialization=on in_to_exists=on semijoin=on partial_match_rowid_merge=on partial_match_table_scan=on subquery_cache=on mrr=offmrr_cost_based=off mrr_sort_keys=off outer_join_with_cache=on semijoin_with_cache=on join_cache_incremental=on join_cache_hashed=onjoin_cache_bka=on optimize_join_buffer_size=on table_elimination=on extended_keys=on exists_to_in=on orderby_uses_equalities=onondition_pushdown_for_derived=on split_materialized=on condition_pushdown_for_subquery=on rowid_filter=oncondition_pushdown_from_having=on not_null_range_scan=off hash_join_cardinality=off cset_narrowing=off sargable_casefold=off	index_merge=on index_merge_union=on index_merge_sort_union=on index_merge_intersection=on index_merge_sort_intersection=offindex_condition_pushdown=on derived_merge=on derived_with_keys=on firstmatch=on loosescan=on materialization=on in_to_exists=onsemijoin=on partial_match_rowid_merge=on partial_match_table_scan=on subquery_cache=on mrr=off mrr_cost_based=off mrr_sort_keys=offouter_join_with_cache=on semijoin_with_cache=on join_cache_incremental=on join_cache_hashed=on join_cache_bka=onoptimize_join_buffer_size=on table_elimination=on extended_keys=on exists_to_in=on orderby_uses_equalities=onondition_pushdown_for_derived=on split_materialized=on condition_pushdown_for_subquery=on rowid_filter=oncondition_pushdown_from_having=on not_null_range_scan=off hash_join_cardinality=on cset_narrowing=on sargable_casefold=on	Added hash_join_cardinality=on, sargable_casefold=on.
OPTIMIZER_ADJUST_SECONDARY_KEY_COSTS	fix_reuse_range_for_ref fix_card_multiplier	0	Weights for secondary key lookups simplified.
SESSION_TRACK_SYSTEM_VARIABLES	autocommit character_set_client character_set_connection character_set_results time_zone	autocommit character_set_client character_set_connection character_set_results time_zone	Added redirect_url to the tracking list.

Options	10.6 Default	11.8 Default	Impact / Note
`VERSION`	`10.6.26-MariaDB-log`	`11.8.7-MariaDB-log`	Metadata only

Deprecated Options

Option	Reason / Recommendation
`tx_isolation`	Replaced by `transaction_isolation`.
`tx_read_only`	Replaced by `transaction_read_only`.
`innodb_purge_rseg_truncate_frequency`	Obsolete due to lighter truncation operations.

Reverse Replication (11.8 to 10.6)

If a critical regression is discovered, you can use an existing 10.6 machine in your setup as a failback safety net.

> **Warning:**
>
> Replicating from a MariaDB 11.8 Primary to a MariaDB 10.6 Replica is NOT officially supported by MariaDB Engineering. This configuration should only be used as a temporary emergency safety net during the upgrade window.

Required 11.8 Primary Configuration

To prevent the 10.6 replica from crashing due to modern metadata (such as the `#2304` character set ID), the 11.8 Primary must be configured to “downgrade” its binary log output using a compatibility file.

The `rollback_compat.cnf` Setup

Create a standalone configuration file to house these temporary reversion settings at `/etc/my.cnf.d/rollback_compat.cnf`

```
[mariadb]
# --- Core 10.6 Behavioral Reversion ---
character_set_server            = latin1
collation_server                = latin1_swedish_ci
explicit_defaults_for_timestamp = OFF
innodb_snapshot_isolation       = OFF

# --- Mandatory Metadata Compatibility (SME "Red" List) ---
# Prevents "Character set #2304" (utf8mb4_uca1400_ai_ci) errors on 10.6
character_set_collations        = ''

# Forces session metadata to legacy-compatible versions
collation_connection            = utf8mb3_general_ci
collation_database              = latin1_swedish_ci

# Standardizes log checksums for the 10.6 parser
binlog_checksum                 = CRC32
```

To activate these settings, append the following line to the end of the `[mariadb]` section in your primary `/etc/my.cnf` file: `!include /etc/my.cnf.d/rollback_compat.cnf`

> **Important:**
>
> **Critical Compatibility Step**
>
> MariaDB 11.8 uses a new default collation ID (#2304) that version 10.6 does not recognize. To prevent the 10.6 replica from crashing, you must set `character_set_collations = ''` on the 11.8 Primary. This forces the Primary to use legacy IDs that the 10.6 machine can process

Known “Breaking” Factors

Certain 11.8 features will immediately break the 10.6 replication link if used:

- Vector Data Types: Any `INSERT` or `UPDATE` involving a `VECTOR(N)` column.
- New Functions: Use of `VEC_Distance` or other 11.8-specific SQL functions.
- Large Row Events: If `binlog_row_event_max_size` is tuned significantly higher than 10.6 defaults.

> **Note:**
>
> **Note on Existing Nodes**
>
> You do not need a new machine for reverse replication. You can use an existing 10.6 node already in your setup. Simply stop replication on that node before the upgrade, and resume it once the 11.8 Primary is configured for compatibility.

Operational Steps for the Safety Net

> **Step 1**
>
> **Isolate a 10.6 Node**
>
> Before upgrading your entire environment, identify one existing replica to remain on version 10.6. Stop the replication on this node just before you upgrade the Primary to 11.8.

> **Step 2**
>
> **Configure 11.8 for Compatibility**
>
> Immediately after installing version 11.8 on your Primary, apply the `rollback_compat.cnf` settings (such as `character_set_collations = ''` and `binlog_checksum = CRC32`).

> **Step 3**
>
> **Start 11.8 and Rotate Logs**
>
> Start the 11.8 service and run `FLUSH LOGS;`. This ensures the Primary begins writing its binary logs in a format the 10.6 replica can understand.

> **Step 4**
>
> **Connect the 10.6 Node**
>
> Point your existing 10.6 machine to the new 11.8 Primary. Because the data on the 10.6 node is already consistent with the pre-upgrade state, it can simply “pick up” the new changes from the 11.8 Primary.

Post-Upgrade Verification

After the data upgrade is complete, verify the functionality of 11.8 features:

- Confirm Version: `SELECT VERSION();` should reflect the 11.8 GA series.
- Confirm Vector Search: Verify the new `VECTOR(N)` data type and conversion functions.

```
CREATE TABLE test_vector (v VECTOR(3));
SELECT VEC_ToText(VEC_FromText('[1,2,3]'));
```

- Verify Optimizer Performance: Prefix any SQL query with ANALYZE FORMAT=JSON on upgraded 11.8 instances to audit the new SSD-aware cost model:

  ```
  ANALYZE FORMAT=JSON SELECT * FROM orders WHERE total > 1000 AND status = 'shipped';
  ```

  This captures real-time execution metrics like `engine_cost` (measured in ms) and `pages_accessed`, verifying that the optimizer is correctly prioritizing high-speed storage over legacy 10.6 logic:

  ```
  "table": {
    "table_name": "orders",
    "access_type": "index_scan",
    "engine_cost": 4.12, // Actual cost in MILLISECONDS (ms)
    "r_engine_stats": {
      "pages_accessed": 142, // Real-world I/O footprint
      "pages_read_time_ms": 1.05 // Precise SSD latency
    }
  }
  ```

- Check Replication Lag Fields: On a replica server, run `SHOW REPLICA STATUS\G` and look for the new `Master_Slave_time_diff` field.

Upgrade from MariaDB Community Server 10.6 to MariaDB Enterprise Server 11.8

This guide outlines a direct upgrade from **MariaDB Community Server 10.6** to **MariaDB Enterprise Server 11.8**. It combines two transitions in a single upgrade window: a product switch (Community to Enterprise) and a major version jump (10.6 to 11.8). With MariaDB Community Server 10.6 approaching end-of-life, this path lets you move to a maintained Enterprise release without an intermediate stop on ES 10.6.

> **Note:**
>
> This guide assumes you are running on a variant of Linux that uses `systemd` to manage services (such as RHEL, CentOS, AlmaLinux, Rocky Linux, Debian, Ubuntu, or SLES).

> **Warning:**
>
> This is a substantial change: a product switch and a major version jump performed back-to-back. Read this guide end-to-end before you start, and rehearse the procedure in a non-production environment first. Review the MariaDB Engineering Policies to confirm your operating system is supported on the 11.8 release series.

Prerequisites

Complete these checks and preparations before stopping your 10.6 service.

Data Backup and Integrity

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. It is generally best to perform a backup prior to upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup.

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_cs10.6_to_es11.8
```

Confirm successful completion of the backup operation.

2. Prepare the backup so it is ready for immediate restoration if required.

```
sudo mariadb-backup --prepare \
      --target-dir=/data/backup/preupgrade_cs10.6_to_es11.8
```

Confirm successful completion of the prepare operation.

3. Verify recoverability: test your backup by restoring it to a non-production environment before proceeding.

Convert InnoDB Row Format

MariaDB Enterprise Server 10.6 and later changed the `COMPRESSED` InnoDB row format to read-only. Before upgrading to MariaDB Enterprise Server 11.8, modify any compressed InnoDB tables on your 10.6 Community Server to use the `DYNAMIC` row format with `PAGE_COMPRESSED=1`.

1. Identify any InnoDB tables that use the `COMPRESSED` row format:

```
SELECT NAME, ROW_FORMAT
FROM information_schema.INNODB_SYS_TABLES
WHERE NAME NOT LIKE 'SYS_%'
   AND ROW_FORMAT = 'COMPRESSED';
```

2. Convert each table to `DYNAMIC` row format with page compression:

```
ALTER TABLE accounts.hq_sales
ROW_FORMAT = DYNAMIC
PAGE_COMPRESSED = 1;
```

Audit Plugin Considerations

If you have the MariaDB Audit Plugin (`server_audit.so`) installed on your Community Server, remove it before upgrading. Otherwise it will conflict with the MariaDB Enterprise Audit Plugin that ships with MariaDB Enterprise Server 10.4 and later.

Remove the plugin by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

If you load the plugin in a configuration file using the `plugin_load_add` option, remove that option as well. The MariaDB Enterprise Audit Plugin is automatically installed when you install MariaDB Enterprise Server.

Compatibility and Legacy Support

These defaults ensure 11.8 keeps behaving like your 10.6 instance for applications that aren't yet ready for the new defaults.

- **Non-default character sets:** If your 10.6 instance uses `latin1` or `utf8mb3`, do not switch to `utf8mb4` immediately. Explicitly define your existing character set in the new `my.cnf` to override the 11.8 defaults.
- **`OLD_MODE` tip:** Set `old_mode = UTF8_IS_UTF8MB3` in your configuration so that `utf8` remains an alias for the legacy 3-byte character set instead of the new 4-byte standard.
- **SSL compatibility:** MariaDB 11.4 and later enable "Zero-configuration TLS" by default. If your application does not support SSL, set `require_secure_transport = OFF` in the `[mariadb]` section of `my.cnf` to prevent

connection refusals.

- **XA transactions:** Run `XA RECOVER;` to identify any external XA transactions in a prepared state. These must be committed or rolled back before the service is stopped.

Environment Compatibility

- **Engineering policy:** Verify your operating system version is supported for the 11.8 series in the MariaDB Engineering Policies.
- **Customer Download Token:** Retrieve your token from https://customers.mariadb.com/downloads/token/. You'll need it to configure the Enterprise repository in the steps below.

The Upgrade Procedure

> **Step 1**
>
> **Perform a Controlled Shutdown of MariaDB Community Server 10.6**
>
> 1. Initiate a fast shutdown so the InnoDB engine closes cleanly:
>
>    ```
>    SET GLOBAL innodb_fast_shutdown = 1;
>    ```
>
> 2. Stop the service:
>
>    ```
>    sudo systemctl stop mariadb
>    ```

Step 2

Purge the MariaDB Community Server 10.6 Packages

When switching from MariaDB Community Server to MariaDB Enterprise Server, it is necessary to remove the existing Community Server installation before installing Enterprise Server. Otherwise, the package manager will refuse to install the Enterprise Server packages.

For Community Server 10.6, the Galera package is `galera-4` (named `galera-3` on APT for some legacy 10.3 installations, but 10.6 always uses `galera-4`).

UNINSTALL VIA YUM

On RHEL, AlmaLinux, CentOS, and Rocky Linux:

```
sudo yum remove "MariaDB-*" galera-4
```

Verify that all MariaDB Community Server packages are uninstalled. The following command should return no results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

UNINSTALL VIA APT

On Debian and Ubuntu:

```
sudo apt-get remove "mariadb-*" galera-4
```

Verify that all MariaDB Community Server packages are uninstalled. The following command should return no results:

```
apt list --installed | grep -i -E "mariadb|galera"
```

UNINSTALL VIA ZYPP

On SLES:

```
sudo zypper remove "MariaDB-*" galera-4
```

Verify that all MariaDB Community Server packages are uninstalled. The following command should return no results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Be sure to check that the wildcard does not unintentionally refer to any of your custom applications.

Step 3

Configure the MariaDB Enterprise Server 11.8 Repository

Download the repository setup script, verify it, and run it with your Customer Download Token to register the 11.8 Enterprise repository. Replace `CUSTOMER_DOWNLOAD_TOKEN` with the token retrieved during Prerequisites, and substitute `${checksum}` with the latest published checksum from the Versions section of the MariaDB Package Repository Setup and Usage page.

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
echo "${checksum}  mariadb_es_repo_setup" | sha256sum -c -
chmod +x mariadb_es_repo_setup
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.8"
```

On APT systems, refresh the package index after running the setup script:

```
sudo apt update
```

Step 4

Install MariaDB Enterprise Server 11.8

The repository setup only configures the source; install the new binaries explicitly.

INSTALL VIA YUM

```
sudo yum install MariaDB-server MariaDB-backup
```

INSTALL VIA APT

```
sudo apt install mariadb-server mariadb-backup
```

INSTALL VIA ZYPP

```
sudo zypper install MariaDB-server MariaDB-backup
```

Installation of additional packages may be required for some plugins. Installation only loads MariaDB Enterprise Server onto the system — configuration is the next step.

Step 5

Implement Version-Specific Configuration Changes

> **Note:**
>
> Do not apply 11.8-specific variables while the 10.6 service is active. During the package swap, update `my.cnf` to adopt the 11.8 defaults for the Optimizer Cost Model. These variables replace legacy hardcoded logic and are essential to the new engine's performance.

- **Scrub** legacy 10.6 variables (`old_alter_table`, etc.) — see Removed, Superseded, or Renamed Options below.
- **Adopt** the new Optimizer Cost Model variables using their 11.8 defaults.
- **Stabilize** with `NEW_MODE = OFF` to prevent unpredictable execution-plan changes on day one.

> **Tip:**
>
> **Recommended `my.cnf` for Version 11.8**

```
[mariadb]
# --- CHARACTER SETS & COLLATIONS ---
# utf8mb4 is the modern default; UCA 14.0.0 is ID #2304
character-set-server  = utf8mb4
collation-server      = utf8mb4_uca1400_ai_ci
# Use old_mode if your app requires 3-byte utf8 aliases
old_mode              = UTF8_IS_UTF8MB3

# --- OPTIMIZER COST MODEL (CRITICAL) ---
# Adopting 11.8 defaults replaces legacy hardcoded logic.
# Set NEW_MODE = OFF to stabilize query plans during initial cutover.
new_mode                        = OFF
optimizer_disk_read_cost        = 10.24
optimizer_disk_read_ratio       = 0.02
optimizer_extra_pruning_depth   = 8
optimizer_index_block_copy_cost = 0.0356
optimizer_key_compare_cost      = 0.011361
optimizer_key_copy_cost         = 0.015685
optimizer_key_lookup_cost       = 0.435777
optimizer_key_next_find_cost    = 0.082347
optimizer_rowid_compare_cost    = 0.002653
optimizer_rowid_copy_cost       = 0.002653
optimizer_row_copy_cost         = 0.060866
optimizer_row_lookup_cost       = 0.130839
optimizer_row_next_find_cost    = 0.045916
optimizer_scan_setup_cost       = 10
optimizer_where_cost            = 0.032

# --- INNODB STORAGE ENGINE ---
innodb_flush_method      = O_DIRECT
innodb_undo_log_truncate = ON
innodb_purge_batch_size  = 1000

# --- REPLICATION SAFETY NET ---
# REQUIRED if you intend to fail back to an existing 10.6 node.
# Fixes "Character set #2304" errors on legacy replicas.
character_set_collations = ''
binlog_alter_two_phase   = 1

# --- COMPLIANCE & CLEANUP ---
transaction_isolation    = REPEATABLE-READ
transaction_read_only    = OFF
```

> If your platform uses YUM or ZYpp, note that MariaDB Enterprise Server's packages bundle the following configuration files: `/etc/my.cnf`, `/etc/my.cnf.d/client.cnf`, `/etc/my.cnf.d/mariadb-enterprise.cnf`, `/etc/my.cnf.d/mysql-clients.cnf`, and `/etc/my.cnf.d/server.cnf`. If your previous Community Server configuration files contained custom edits, the package manager may save your edited version with the `.rpmsave` extension during installation. Restore your edits before starting the new server.

> **Step 6**
>
> **Bring the Service Online and Run mariadb-upgrade**
>
> 1. Start the new service:
>
>    ```
>    sudo systemctl start mariadb
>    ```
>
> 2. Run the data-directory upgrade utility. It corrects system table structures and marks data files as compatible with version 11.8:
>
>    ```
>    sudo mariadb-upgrade
>    ```

Incompatible and Significant Changes

The following variables from version 10.6 have been removed, renamed, or deprecated in the 11.8 release series.

New Variables Added in 11.8

> **Note:**
>
> Once the 11.8 binaries are installed, update your `my.cnf` to define these new variables.

Optimizer Cost Model Variables

> **Warning:**
>
> **Handle with care.** The 11.8 engine uses a new weighting system designed for modern storage (SSDs). Altering these variables without extensive benchmarks can lead to severe performance degradation or inefficient query execution plans. Keep these at their defaults upon upgrade unless you are performing expert-level performance tuning.

These variables define the weights of the new optimizer. If query execution plans change after the upgrade, these parameters are the primary audit points and represent the optimizer cost model.

Variable Name	11.8 Default	Note
`NEW_MODE`	`OFF`	
`OPTIMIZER_DISK_READ_COST`	`10.24`	**Optimizer Plan Consistency:** Row-based replication (RBR) remains unaffected by these changes. However, because the 11.8 Primary uses the new cost model while legacy 10.6 nodes use hardcoded logic, query execution plans may differ significantly between Master and Slave.
`OPTIMIZER_DISK_READ_RATIO`	`0.02`	
`OPTIMIZER_EXTRA_PRUNING_DEPTH`	`8`	

Variable Name	11.8 Default	Note
OPTIMIZER_INDEX_BLOCK_COPY_COST	0.0356	
OPTIMIZER_KEY_COMPARE_COST	0.011361	
OPTIMIZER_KEY_COPY_COST	0.015685	
OPTIMIZER_KEY_LOOKUP_COST	0.435777	
OPTIMIZER_KEY_NEXT_FIND_COST	0.082347	
OPTIMIZER_ROWID_COMPARE_COST	0.002653	
OPTIMIZER_ROWID_COPY_COST	0.002653	
OPTIMIZER_ROW_COPY_COST	0.060866	
OPTIMIZER_ROW_LOOKUP_COST	0.130839	
OPTIMIZER_ROW_NEXT_FIND_COST	0.045916	
OPTIMIZER_SCAN_SETUP_COST	10	
OPTIMIZER_WHERE_COST	0.032	

InnoDB Variables

InnoDB used complex buffering (such as the Change Buffer) to delay writes because hard drives were slow at random I/O. In version 11.8 these legacy layers are stripped back. The following InnoDB system variables let MariaDB communicate more directly with modern SSD/NVMe storage, reducing the “middleman” overhead of the operating system’s cache.

Variable Name	11.8 Default
INNODB_ADAPTIVE_HASH_INDEX_CELLS ^	34679
INNODB_ALTER_COPY_BULK #	ON
INNODB_BUFFER_POOL_SIZE_AUTO_MIN	134217728
INNODB_BUFFER_POOL_SIZE_MAX	134217728
INNODB_DATA_FILE_BUFFERING	OFF
INNODB_DATA_FILE_WRITE_THROUGH	OFF
INNODB_LINUX_AIO	auto
INNODB_LOG_CHECKPOINT_NOW	OFF
INNODB_LOG_FILE_BUFFERING	OFF
INNODB_LOG_FILE_MMAP	OFF
INNODB_LOG_FILE_WRITE_THROUGH	OFF
INNODB_LOG_SPIN_WAIT_DELAY	0
INNODB_TRUNCATE_TEMPORARY_TABLESPACE_NOW	OFF

Replication and Binlog Variables

As clusters grow, managing the Global Transaction ID (GTID) list becomes a performance bottleneck. 11.8 introduces “GTID Indexing,” which treats the replication log more like a database table, allowing near-instant lookups when a replica reconnects. See Replication and Binary Logging Variables for details.

Variable Name	11.8 Default	Note
`BINLOG_ALTER_TWO_PHASE` #	`OFF`	
`BINLOG_DO_DB`	`(None)`	
`BINLOG_GTID_INDEX` #	`ON`	
`BINLOG_GTID_INDEX_PAGE_SIZE` #	`4096`	
`BINLOG_GTID_INDEX_SPAN_MIN` #	`65536`	
`BINLOG_IGNORE_DB`	`(None)`	
`BINLOG_LARGE_COMMIT_THRESHOLD`	`134217728`	
`BINLOG_LEGACY_EVENT_POS` #	`OFF`	
`BINLOG_ROW_EVENT_MAX_SIZE` #	`8192`	Packet safety: ensure this value on the 11.8 Primary is strictly lower than the `MAX_ALLOWED_PACKET` setting on your 10.6 Replicas. If an 11.8 row event exceeds the legacy replica's packet limit, replication will fail with a "Packet too large on slave" error.
`BINLOG_SPACE_LIMIT`	`0`	
`REPLICATE_REWRITE_DB` #	`(None)`	
`SLAVE_ABORT_BLOCKING_TIMEOUT`	`31536000`	
`SLAVE_CONNECTIONS_NEEDED_FOR_PURGE` #	`1`	**Binary log purge safety:** The default value is `1`. If your topology requires that binary logs be retained until acknowledged by multiple replicas, increase this value to prevent the primary from purging logs before all critical slaves have synchronized the data.
`SLAVE_MAX_STATEMENT_TIME`	`0`	

Advanced Logging Variables

Slow logging was often a blunt instrument that could either miss critical spikes or flood the disk with useless data. Version 11.8 introduces granular filters: you can ignore queries that touch many rows but are still fast, or ensure that queries exceeding a specific “emergency” duration are always captured regardless of other filters. See Server System Variables for details.

Variable Name	11.8 Default
`LOG_SLOW_ALWAYS_QUERY_TIME`	`31536000`
`LOG_SLOW_MIN_EXAMINED_ROW_LIMIT`	`0`
`LOG_SLOW_QUERY`	`OFF`
`LOG_SLOW_QUERY_FILE`	`(Host Specific)`
`LOG_SLOW_QUERY_TIME`	`10`

Security and Authentication Variables

MariaDB 11.8 shifts toward modern cryptographic standards. This includes better handling of User-Defined Functions (UDFs) and a transition toward the caching_sha2_password plugin, which provides significantly stronger protection against man-in-the-middle and brute-force attacks compared to legacy authentication.

Variable Name	11.8 Default
`ALLOW_SUSPICIOUS_UDFS`	`OFF`
`SKIP_GRANT_TABLES` #	`OFF`

Resource Limits Variables

A single unoptimized query could theoretically consume all available disk space by creating a massive temporary table, crashing the operating system. Version 11.8 introduces safety valves that let administrators set hard limits on how much temporary space a single session or the entire server can use.

Variable Name	11.8 Default
`MAX_BINLOG_TOTAL_SIZE`	`0`
`MAX_TMP_SESSION_SPACE_USAGE`	`1099511627776` (1TB)
`MAX_TMP_TOTAL_SPACE_USAGE`	`1099511627776` (1TB)

Vector Search / MHNSW Variables

MariaDB 11.8 introduces a native Vector Search engine using the Metadata-HNSW (Hierarchical Navigable Small Worlds) algorithm. This allows the database to store and query embeddings (mathematical representations of text/images), enabling AI-powered semantic search directly within the SQL layer.

> **Note:**
>
> Vector Search is entirely absent from MariaDB 10.6.
>
> - Primary config: use `MHNSW_DEFAULT_DISTANCE` to define semantic search logic (default: `euclidean`).
> - Compatibility warning: legacy 10.6 replicas cannot process vector data types or SQL functions; using them will break the replication link.

Variable Name	11.8 Default
`MHNSW_DEFAULT_DISTANCE` #	`euclidean`
`MHNSW_DEFAULT_M`	`6`

Variable Name	11.8 Default
`MHNSW_EF_SEARCH`	`20`
`MHNSW_MAX_CACHE_SIZE`	`16777216`

General Architecture Changes Variables

The final group of changes focuses on renaming legacy variables for industry compliance (SQL Standard) and adding features that improve how the database communicates with external tools such as proxies or system-versioning audit logs.

Variable Name	11.8 Default	Note
`REDIRECT_URL` #	`(None)`	**Replication redirection safety:** `REDIRECT_URL` lets the server send redirection hints to proxies or clients. **Crucial:** configure this carefully on replicas to ensure internal slave-to-primary connections are not redirected, as accidental redirection of replication traffic will break the sync link.
`SYSTEM_VERSIONING_INSERT_HISTORY` #	`OFF`	**System versioning & binlog replay:** The default is acceptable for standard operations. Because MariaDB 11.8's `mariadb-binlog` utility explicitly prints this value in its output, replaying binary logs with the 11.8 version of the tool is not recommended during the transition period.
`BLOCK_ENCRYPTION_MODE` ^	`aes-128-ecb`	The 11.8 default is fine, but exercise care when calling `AES_ENCRYPT` and `AES_DECRYPT`; the syntax differs from 10.6.
`CHARACTER_SET_COLLATIONS` #	`utf8mb4=…`	`character_set_collations` must be empty for reverse replication (11.8 → 10.6).
`TRANSACTION_ISOLATION` #	`REPEATABLE-READ`	
`TRANSACTION_READ_ONLY` #	`OFF`	
`WSREP_ALLOWLIST`	`(None)`	
`WSREP_STATUS_FILE`	`(None)`	

> **Important:**
>
> #**Handle with extra care.** These variables have the highest impact on system stability and performance; please review during your configuration updates.

> **Warning:**
>
> ^**Caution.** These variables may impact system stability and performance; please review during your configuration updates.

Options to Remove, Rename, or Update in 11.8

Removed, Superseded, or Renamed Options

During the maintenance window (after stopping 10.6 and before starting 11.8), you must scrub your `my.cnf` of all removed, superseded, and renamed options.

Variable Name	10.6 Default	Technical Action / Replacement
`DATETIME_FORMAT` [2]	`%Y-%m-%d %H:%i:%s`	Scrub. 11.8 enforces standard internal format strings.
`DATE_FORMAT` [2]	`%Y-%m-%d`	Scrub. Enforced standard format.
`DEBUG_NO_THREAD_ALARM` [1]	`OFF`	Remove. Retired legacy debug code.
`INNODB_CHANGE_BUFFERING` [2]	`none`	Scrub. Logic replaced by SSD-optimized write paths.
`INNODB_CHANGE_BUFFER_MAX_SIZE` [1]	`25`	Remove. Buffer size is now managed internally by the engine.
`INNODB_DEFRAGMENT` [2]	`OFF`	Scrub. Manual defragmentation is no longer supported.
`INNODB_DEFRAGMENT_FILL_FACTOR` [2]	`0.9`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_FILL_FACTOR_N_RECS` [2]	`20`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_FREQUENCY` [2]	`40`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_N_PAGES` [2]	`7`	Scrub. Feature retired; logic is now internal.
`INNODB_DEFRAGMENT_STATS_ACCURACY` [2]	`0`	Scrub. Feature retired; logic is now internal.
`INNODB_VERSION` [1]	`10.6.26`	Remove. Versioning is consolidated in global server metadata.
`MAX_TMP_TABLES` [1]	`32`	Remove. Internal temp table management is now automated.
`OLD_ALTER_TABLE` [1]	`DEFAULT`	Remove. Superseded by `ALTER_ALGORITHM`.
`TIME_FORMAT` [2]	`%H:%i:%s`	Scrub. Enforced standard format.
`WSREP_CAUSAL_READS` [2]	`OFF`	Scrub. Superseded by `wsrep_sync_wait`.
`WSREP_LOAD_DATA_SPLITTING` [1]	`OFF`	Remove. Legacy Galera splitting logic retired.
`WSREP_REPLICATE_MYISAM` [1]	`OFF`	Remove. Galera no longer supports MyISAM replication.
`WSREP_STRICT_DDL` [1]	`OFF`	Remove. Replaced by `wsrep_mode=STRICT_REPLICATION`.

Important:

[1]**Fatal error.** MariaDB 11.8 will abort startup if these legacy parameters are detected in the configuration file. They MUST be removed before restart to prevent upgrade failure.

Example: `[ERROR] /usr/sbin/mariadbd: unknown variable 'MAX_TMP_TABLES=32'`

Warning:

[2]**Warning.** MariaDB 11.8 will start but log a warning if these legacy parameters are detected in the configuration file. Scrub them during the upgrade to maintain configuration hygiene and ensure settings reflect active 11.8 features.

Warning example: `[Warning] 'innodb-change-buffering' was removed. It does nothing now and exists only for compatibility with old my.cnf files.`

Options That Have Changed Default Values

Note:

For variables that exist in both versions but have different defaults (such as `innodb_purge_batch_size`), the 11.8 engine automatically applies the new value. If you require identical behavior to your 10.6 environment during the initial cutover, hardcode the 10.6 values into your new configuration file.

Option	10.6 Default	11.8 Default	Impact / Note
`character_set_server`	`latin1`	`utf8mb4`	Global default encoding shift.
`CHARACTER_SET_CLIENT`	`latin1`	`utf8mb4`	Modern standard for client connections.

Option	10.6 Default	11.8 Default	Impact / Note
`CHARACTER_SET_CONNECTION`	`latin1`	`utf8mb4`	Modern standard for session connections.
`CHARACTER_SET_DATABASE`	`latin1`	`utf8mb4`	Modern standard for database storage.
`CHARACTER_SET_RESULTS`	`latin1`	`utf8mb4`	Modern standard for query results.
`collation_server`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Transition to the modern Unicode collation standard.
`COLLATION_CONNECTION`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Update to modern Unicode Collation Algorithm (UCA).
`COLLATION_DATABASE`	`latin1_swedish_ci`	`utf8mb4_uca1400_ai_ci`	Update to modern Unicode Collation Algorithm (UCA).
`EXPLICIT_DEFAULTS_FOR_TIMESTAMP`	`OFF`	`ON`	Impacts `NULL` handling in `TIMESTAMP` columns. Modify for reverse replication (11.8 → 10.6) to maintain the same behavior on master and slave.
`HAVE_SSL`	`DISABLED`	`YES`	SSL/TLS is now natively available and enabled by default.
`HISTOGRAM_TYPE`	(Empty)	`JSON_HB`	Optimizer now stores histogram stats in JSON format. Modify for reverse replication (11.8 → 10.6).
`INNODB_BUFFER_POOL_CHUNK_SIZE`	`134217728`	`0`	Set to `0` to enable automatic calculation.
`INNODB_LOG_WRITE_AHEAD_SIZE`	`8192`	`4096`	Optimized for modern storage block alignment.
`innodb_snapshot_isolation`	`OFF`	`ON`	Enabled by default for improved consistency.
`innodb_undo_tablespaces`	`0`	`3`	Enables online truncation of undo logs.
`optimizer_prune_level`	`1`	`2`	Primary audit point for plan changes.
`VERSION`	`10.6.26-MariaDB-log`	`11.8.7-MariaDB-log`	Metadata only.

Deprecated Options

Option	Reason / Recommendation
`tx_isolation`	Replaced by `transaction_isolation`.
`tx_read_only`	Replaced by `transaction_read_only`.
`innodb_purge_rseg_truncate_frequency`	Obsolete due to lighter truncation operations.

Reverse Replication (11.8 to 10.6)

If a critical regression is discovered, you can use an existing 10.6 machine in your setup as a failback safety net.

> **Warning:**
>
> Replicating from a MariaDB 11.8 Primary to a MariaDB 10.6 Replica is NOT officially supported by MariaDB Engineering. This configuration should only be used as a temporary emergency safety net during the upgrade window.

Required 11.8 Primary Configuration

To prevent the 10.6 replica from crashing due to modern metadata (such as the `#2304` character set ID), the 11.8 Primary must be configured to “downgrade” its binary log output using a compatibility file.

The `rollback_compat.cnf` Setup

Create a standalone configuration file to house these temporary reversion settings at `/etc/my.cnf.d/rollback_compat.cnf`:

```
[mariadb]
# --- Core 10.6 Behavioral Reversion ---
character_set_server            = latin1
collation_server                = latin1_swedish_ci
explicit_defaults_for_timestamp = OFF
innodb_snapshot_isolation       = OFF

# --- Mandatory Metadata Compatibility ---
# Prevents "Character set #2304" (utf8mb4_uca1400_ai_ci) errors on 10.6
character_set_collations        = ''

# Force session metadata to legacy-compatible versions
collation_connection            = utf8mb3_general_ci
collation_database              = latin1_swedish_ci

# Standardize log checksums for the 10.6 parser
binlog_checksum                 = CRC32
```

To activate these settings, append the following line to the end of the `[mariadb]` section in your primary `/etc/my.cnf` file: `!include /etc/my.cnf.d/rollback_compat.cnf`

> **Important:**
>
> **Critical Compatibility Step**
>
> MariaDB 11.8 uses a new default collation ID (#2304) that version 10.6 does not recognize. To prevent the 10.6 replica from crashing, you must set `character_set_collations = ''` on the 11.8 Primary. This forces the Primary to use legacy IDs that the 10.6 machine can process.

Known “Breaking” Factors

Certain 11.8 features will immediately break the 10.6 replication link if used:

- **Vector data types:** any `INSERT` or `UPDATE` involving a `VECTOR(N)` column.
- **New functions:** use of `VEC_Distance` or other 11.8-specific SQL functions.
- **Large row events:** if `binlog_row_event_max_size` is tuned significantly higher than 10.6 defaults.

> **Note:**
>
> **Note on Existing Nodes**
>
> You do not need a new machine for reverse replication. You can use an existing 10.6 node already in your setup — stop replication on that node before the upgrade and resume it once the 11.8 Primary is configured for compatibility.

Operational Steps for the Safety Net

> **Step 1**
>
> **Isolate a 10.6 Node**
>
> Before upgrading your entire environment, identify one existing replica to remain on version 10.6. Stop replication on this node just before you upgrade the Primary to 11.8.

> **Step 2**
>
> **Configure 11.8 for Compatibility**
>
> Immediately after installing version 11.8 on your Primary, apply the `rollback_compat.cnf` settings (such as `character_set_collations = ''` and `binlog_checksum = CRC32`).

> **Step 3**
>
> **Start 11.8 and Rotate Logs**
>
> Start the 11.8 service and run `FLUSH LOGS;`. This ensures the Primary begins writing its binary logs in a format the 10.6 replica can understand.

> **Step 4**
>
> **Connect the 10.6 Node**
>
> Point your existing 10.6 machine to the new 11.8 Primary. Because the data on the 10.6 node is already consistent with the pre-upgrade state, it can simply pick up the new changes from the 11.8 Primary.

Post-Upgrade Verification

After the data upgrade is complete, verify the functionality of 11.8 features.

1. Confirm the server version:

   ```
   SELECT VERSION();
   ```

   The result should reflect the 11.8 GA series.

2. Confirm Vector Search by verifying the new `VECTOR(N)` data type and conversion functions:

   ```
   CREATE TABLE test_vector (v VECTOR(3));
   SELECT VEC_ToText(VEC_FromText('[1,2,3]'));
   ```

3. Verify optimizer performance by prefixing any SQL query with `ANALYZE FORMAT=JSON` to audit the new SSD-aware cost model:

   ```
   ANALYZE FORMAT=JSON SELECT * FROM orders WHERE total > 1000 AND status = 'shipped';
   ```

   The output includes real-time execution metrics such as `engine_cost` (measured in milliseconds) and `pages_accessed`, verifying that the optimizer is correctly prioritizing high-speed storage over legacy 10.6 logic:

   ```
   "table": {
     "table_name": "orders",
     "access_type": "index_scan",
     "engine_cost": 4.12,
     "r_engine_stats": {
       "pages_accessed": 142,
       "pages_read_time_ms": 1.05
     }
   }
   ```

4. On a replica server, run `SHOW REPLICA STATUS\G` and look for the new `Master_Slave_time_diff` field.

Upgrade to MariaDB Enterprise Server 11.4

Overview

These instructions detail the **upgrade** from a previous version of **MariaDB Enterprise Server** to **MariaDB Enterprise Server 11.4** on a range of supported Operating Systems.

When MariaDB Enterprise Server is upgraded, the old version needs to be uninstalled, and the new version needs to be installed.

See What's New in MariaDB Enterprise Server 11.4.

Incompatible Changes

MariaDB Enterprise Server 11.4 includes changes from previous release series (10.11, 11.0, 11.1, etc.). If you are upgrading from **MariaDB Enterprise Server 10.6** or older, you are skipping several major versions. Review the following breaking changes to ensure application stability.

Removed Variables (Action Required)

The following variables have been removed. You **must remove** them from your configuration files (`my.cnf`, `.ini`) before starting the upgrade, or the server will fail to start:

- **`innodb_defragment`**: (and all associated variables like `innodb_defragment_fill_factor`, `innodb_defragment_n_pages`).
- **`des_encrypt`** / **`des_decrypt`**: These functions have been removed.
- **`innodb_version`**: This variable is removed as it was redundant.

Behavior Changes & Deprecations

- **Binary Names**: Scripts using `mysql`, `mysqldump`, or `mysqladmin` may fail or emit deprecation warnings. Update automation to use `mariadb`, `mariadb-dump`, and `mariadb-admin`.
- **Compression Plugins**: If you used non-zlib compression (like `lz4` or `lzo`) in 10.6, ensure you have the necessary provider plugins installed in 11.4. Tables may be unreadable until the correct `mariadb-plugin-provider-*` package is installed.
- **Spider Engine**: Default values for Spider buffers (e.g., `spider_buffer_size`) have changed significantly (often autosized). If you rely on specific Spider tuning from 10.6, verify your settings.

- **Replication (GTID)**: ES 11.4 defaults to stricter GTID consistency. If upgrading a cluster, ensure Replicas are compatible before upgrading the Primary.
- **InnoDB Redo Log**: The `innodb_log_file_size` variable is now dynamic and largely ignored. The physical format of the redo log changed in 10.9; ensure you have a valid logical backup (mariadb-dump) before upgrading.
- **Optimizer (Cost Model)**: The Query Optimizer was rewritten in version 11.0. Execution plans may change. It is recommended to run `ANALYZE TABLE` on major tables after the upgrade.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup before upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup. On MariaDB Enterprise Server 11.4 and later:

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the backup operation.

2. The backup must be prepared. On the MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-backup --prepare \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Audit Plugin Considerations

If you have the MariaDB Audit Plugin installed and are upgrading from MariaDB Enterprise Server 10.2 or 10.3, the audit plugin should be removed prior to the upgrade to prevent conflicts with the MariaDB Enterprise Audit Plugin, which MariaDB Enterprise Audit Plugin that is present in MariaDB Enterprise Server 10.4 or later. It can be removed by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

And if you load the plugin in a configuration file using the `plugin\_load\_add` option, then the option should also be removed. The MariaDB Enterprise Audit Plugin will automatically be installed after installing MariaDB Enterprise Server 10.4 or later.

Uninstall the Old Version

When upgrading to a new major release of MariaDB Enterprise Server, it is necessary to remove the existing installation of MariaDB Enterprise Server before installing the new version of MariaDB Enterprise Server. Otherwise, the package manager will refuse to install the new version of MariaDB Enterprise Server.

Stop the MariaDB Server Process

Before the old version can be uninstalled, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to 1:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

```
XA RECOVER;
```

Commit or roll back any open XA transactions before stopping the node for upgrade.

3. Stop the server process: For distributions that use `systemd` (most supported OSes), you can manage the server process using the `systemctl` command:

```
sudo systemctl stop mariadb
```

Uninstall via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo yum remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications:

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called `galera-enterprise-4`:

```
sudo yum remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Uninstall via APT (Debian, Ubuntu)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo apt-get remove "mariadb-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo apt remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
apt list --installed | grep -i -E "mariadb|galera"
```

Uninstall via ZYpp (SLES)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo zypper remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo zypper remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

   To configure YUM package repositories:

```
sudo yum install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo yum install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository. Installable versions of MariaDB Enterprise Server are `11.8 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

   To configure APT package repositories:

```
sudo apt install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

```
sudo apt update
```

3. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup galera-enterprise-4
```

4. Installation of additional packages may be required for some plugins. Configure MariaDB. Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the ZYpp package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure ZYpp package repositories:

```
sudo zypper install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

Note:

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo zypper install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Configuration

For platforms that use YUM or ZYpp as a package manager: MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back.

For example, to move `server.cnf` back in place:

```
sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to `start, stop, restart, enable/disable` on boot, and check the status of the Server using the operating system's default process management system.

For distributions that use `systemd`, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called `mariadb-upgrade` in MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account. MariaDB Client is called `mariadb` (ES 10.4 and later):

```
sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 9
Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL VARIABLES LIKE 'version';
```

```
+---------------+----------------------------+
| Variable_name | Value                      |
+---------------+----------------------------+
| version       | 11.4.5-3-MariaDB-Enterprise |
+---------------+----------------------------+
```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+----------------------------+
| VERSION()                  |
+----------------------------+
| 11.4.5-3-MariaDB-Enterprise |
+----------------------------+
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

Upgrade MariaDB Enterprise Server from 11.4.X to 11.4.Y

These instructions detail a **minor release upgrade** with **MariaDB Enterprise Server 11.4** on a range of supported Operating Systems.

A minor release upgrade is a change from an earlier release of MariaDB Enterprise Server 11.4 to a later release in the same release series.

For example, it would be a minor release upgrade to upgrade from MariaDB Enterprise Server 11.4.4-2 to MariaDB Enterprise Server 11.4.5-3.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup prior to upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup.

   On MariaDB Enterprise Server 10.4 and later:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Enterprise Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the backup operation.

2. The backup must be prepared.

   On MariaDB Enterprise Server 10.4 and later:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Enterprise Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Stop the MariaDB Server Process

Before the new version can be installed, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to `1`:

   ```
   SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

   ```
   XA RECOVER;
   ```

   Commit or rollback any open XA transactions before stopping the node for upgrade.

3. Stop the server process:

   For distributions that use systemd (most supported OSes), you can manage the Server process using the `systemctl` command:

   ```
   $ sudo systemctl stop mariadb
   ```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

INSTALL VIA YUM

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure YUM package repositories:

   ```
   $ sudo yum install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="11.4"
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Update MariaDB Enterprise Server and package dependencies:

```
$ sudo yum update "MariaDB-*" "galera*"
```

INSTALL VIA APT

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure APT package repositories:

   ```
   $ sudo apt install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="11.4"
   ```

   ```
   $ sudo apt update
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Update MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo apt install --only-upgrade "mariadb-*" "galera*"
   ```

INSTALL VIA ZYPP

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the ZYpp package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure ZYpp package repositories:

   ```
   $ sudo zypper install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Update MariaDB Enterprise Server and package dependencies:

```
$ sudo zypper update "MariaDB-*" "galera*"
```

Configuration

For platforms that use YUM or ZYpp as a package manager:

MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back. For example, to move `server.cnf` back in place:

```
$ sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
$ sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use systemd, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called mariadb-upgrade in MariaDB Enterprise Server 10.4 and later:

```
$ sudo mariadb-upgrade
```

And the utility is called mysql_upgrade in MariaDB Enterprise Server 10.3 and 10.2:

```
$ sudo mysql_upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account.

   MariaDB Client is called mariadb (ES10.4 and later) or `mysql` (ES10.3, ES10.2):

   ```
   $ sudo mariadb
   ```

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   Your MariaDB connection id is 9
   Server version: 11.4.5-3-MariaDB-Enterprise MariaDB Enterprise Server

   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

   MariaDB [(none)]>
   ```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

   ```
   SHOW GLOBAL VARIABLES LIKE 'version';
   ```

   ```
   +---------------+----------------------------+
   | Variable_name | Value                      |
   +---------------+----------------------------+
   | version       | 11.4.5-3-MariaDB-Enterprise |
   +---------------+----------------------------+
   ```

3. You can also verify the server version by calling the VERSION() function:

   ```
   SELECT VERSION();
   ```

   ```
   +----------------------------+
   | VERSION()                  |
   +----------------------------+
   | 11.4.5-3-MariaDB-Enterprise |
   +----------------------------+
   ```

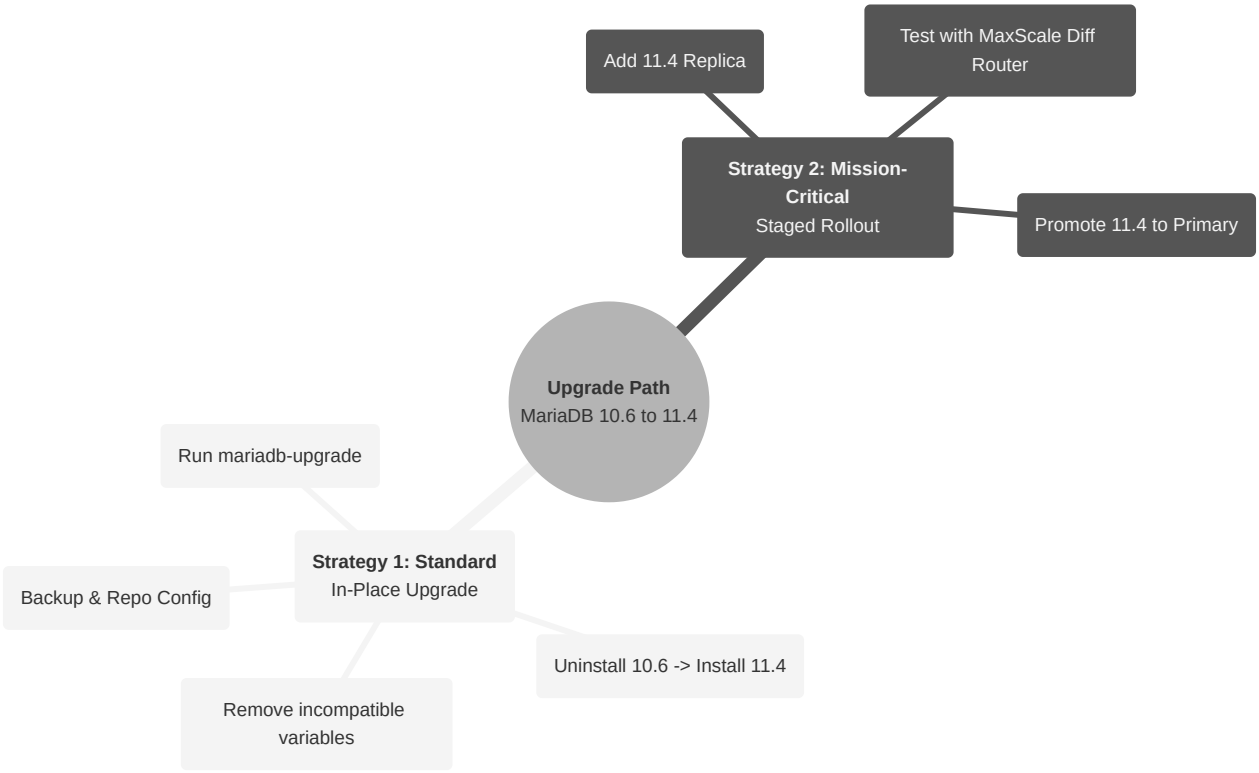
Upgrade MariaDB Enterprise Server from 10.6 to 11.4

The upgrade guide details the standard upgrade path from MariaDB Enterprise Server 10.6 to MariaDB Enterprise Server 11.4. The upgrade process involves significant changes, particularly to the query optimizer, which was rewritten in version 11.0. While performance is generally improved, query execution plans may change.

This guide provides two strategies:

1. Standard In-Place Upgrade: The direct procedure for upgrading an existing node.
2. Staged Rollout (Recommended for Mission-Critical Systems): A low-risk approach using replication and validation.



Prerequisite: Review What's New in MariaDB Enterprise Server 11.4.

Part 1: Standard In-Place Upgrade Process

This section details the standard procedure for performing an in-place upgrade. This involves replacing the server binaries while keeping the data directory intact.

> **Step 1**
>
> **Backup Database**
>
> Before performing any upgrade, it is critical to perform a full backup of your database. MariaDB Backup (`mariadb-backup`) is recommended for this purpose.

```
# Example backup command
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_backup
```

Step 2

Modify Repository Configuration

Update your system's package manager repository to point to MariaDB Enterprise Server 11.4. You will need to regenerate your repository configuration command using the MariaDB Customer Download Token.

APT (DEBIAN/UBUNTU)

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply --mariadb-server-version="11.4"
```

YUM (RHEL/CENTOS/ROCKY)

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply --mariadb-server-version="11.4"
```

ZYPP (SLES)

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply --mariadb-server-version="11.4"
```

Step 3

Stop MariaDB Service

Stop the running `mariadbd` process to release locks on the data files.

```
sudo systemctl stop mariadb
```

> **Warning:**
>
> Ensure `innodb_fast_shutdown` is set to `1` and check for open XA transactions before stopping.

Step 4

Uninstall Old Version

Remove the existing MariaDB 10.6 packages. This removes the binaries but preserves the configuration and data directory.

DEBIAN/UBUNTU

```
sudo apt-get remove "mariadb-*" galera-enterprise-4
```

RHEL/CENTOS/ROCKY

```
sudo yum remove "MariaDB-*" galera-enterprise-4
```

Step 5

Install New Version

Install the new MariaDB 11.4 packages.

DEBIAN/UBUNTU

```
sudo apt-get install mariadb-server mariadb-backup galera-enterprise-4
```

RHEL/CENTOS/ROCKY

```
sudo yum install MariaDB-server MariaDB-backup
```

Step 6

Update Configuration (Critical)

Before starting the server, you must update your option files (e.g., `my.cnf`) to remove unsupported parameters.

- Remove `innodb_defragment`: This variable and its associated options (e.g., `innodb_defragment_fill_factor`) have been removed.
- Remove `optimizer_adjust_secondary_key_costs`: This variable has no effect in 11.4 and must be removed.
- Check `innodb_flush_method`: This variable is deprecated in 11.4.

Step 7

Start MariaDB Service

Start the new `mariadbd` process.

```
sudo systemctl start mariadb
```

Step 8

Run mariadb-upgrade (Critical)

Execute `mariadb-upgrade` to check and update system tables to be compatible with the new version.

```
sudo mariadb-upgrade
```

Part 2: Alternative Strategy: Staged Rollout for Mission-Critical Systems

For environments sensitive to performance changes or requiring zero downtime, the following staged rollout strategy is recommended.

Step 1

Introduce Replica

Provision a new server with MariaDB Enterprise Server 11.4 and configure it as a Replica of your existing 10.6 Primary server.

1. **Perform Backup on Primary (10.6)**: Use `mariadb-backup` to create a consistent, non-blocking physical backup.

```
# On the 10.6 Primary
sudo mariadb-backup --backup \
    --user=backup_user \
    --password=backup_password \
    --target-dir=/data/backup/preupgrade_backup
```

2. **Prepare the Backup**: Prepare the backup to ensure consistency (this can be done on the Primary or the Replica).

```
sudo mariadb-backup --prepare \
    --target-dir=/data/backup/preupgrade_backup
```

3. **Restore on Replica (11.4)**: Transfer the backup to the new 11.4 server, stop the service, and restore.

```
# On the 11.4 Replica
sudo systemctl stop mariadb

# Ensure datadir is empty
sudo rm -rf /var/lib/mysql/*

# Restore backup
sudo mariadb-backup --copy-back \
    --target-dir=/data/backup/preupgrade_backup

# Fix permissions
sudo chown -R mysql:mysql /var/lib/mysql
```

4. **Start and Configure Replication:** Start the 11.4 server and configure it to replicate from the 10.6 Primary.

```
sudo systemctl start mariadb
```

Log in to the 11.4 Replica and enable replication. (Note: Ensure `server_id` is unique in `my.cnf`).

```
-- On the 11.4 Replica
-- Set the GTID position (found in the xtrabackup_binlog_info file from the backup)
SET GLOBAL gtid_slave_pos = '0-1-12345'; -- Replace with your actual GTID

CHANGE MASTER TO
    MASTER_HOST='10.6._primary_ip',
    MASTER_USER='replication_user',
    MASTER_PASSWORD='replication_password',
    MASTER_USE_GTID=slave_pos;

START SLAVE;
```

Step 2

Validate and Compare (Recommended)

To proactively catch performance regressions caused by the optimizer rewrite, use MaxScale with the Diff Router(Enterprise feature).

1. Configure MaxScale Ensure your MaxScale `maxscale.cnf` defines both the existing service (routing to 10.6) and the new 11.4 server definition.
2. Create the Diff Service Use `maxctrl` to create a “Diff” service that compares the output of your existing production server against the new 11.4 replica.

```
# Syntax: maxctrl call command diff create <NewDiffServiceName> <ExistingService> <ReferenceServer>
<TargetServer>

maxctrl call command diff create DiffService ReadWriteService Primary10.6 Replica11.4
```

3. Analyze Results MaxScale will generate JSON reports in its log directory (e.g., `/var/lib/maxscale/diff/`). Analyze these files to identify queries that return different results or have significantly higher latency on the 11.4 server.

Step 3

Shift Read Traffic

Gradually migrate read-only traffic to the 11.4 replica.

Update MaxScale Routing If using MaxScale, you can adjust the server weights or maintenance modes to direct read traffic.

```
# Put the 10.6 replicas into maintenance mode or lower their weight
maxctrl set server Primary10.6 maintenance
```

> **Note:**
>
> Alternatively, update your application connection strings to point to the 11.4 Replica’s IP for reporting modules.

Step 4

Promote to Primary

Once the 11.4 replica has been validated under load, promote it to be the Primary node.

1. Stop Replication on 11.4 Replica

```
-- On the 11.4 Replica
STOP SLAVE;
RESET SLAVE ALL;
```

2. Enable Writes on 11.4 New Primary

```
SET GLOBAL read_only=0;
```

3. Direct Traffic Update MaxScale or your application configuration to point to the new 11.4 Primary.

Step 5

Shift Application Traffic

Direct your application traffic to the new 11.4 Primary. Ensure you perform a `mariadb-upgrade` on the new Primary if it hasn't been run yet (though `mariadb-backup` restore usually preserves the old system tables, running upgrade is a safety step to ensure system tables are fully compatible with 11.4).

```
sudo mariadb-upgrade
```

Part 3: Critical Upgrade Information

Step 1

Optimizer Changes and Application Testing

The Query Optimizer was rewritten in version 11.0. While performance is generally better, query plans can change. It is vital to perform validation (as described in the Staged Rollout section) to catch regressions before production deployment. You should also run `ANALYZE TABLE` on major tables after upgrading to update statistics.

Step 2

Required Configuration Changes

The following variables must be addressed in your configuration files (`my.cnf`) to prevent startup failures or warnings:

- `optimizer_adjust_secondary_key_costs`: MUST REMOVE. This variable has no effect in 11.4 as features are integrated into the new cost model.
- `innodb_defragment`: MUST REMOVE. This variable has been removed.
- `des_encrypt` / `des_decrypt`: Functions have been removed.

Step 3

Backward Replication Compatibility

You can replicate from a MariaDB 11.4 Primary to a MariaDB 10.6 Replica (Backward Replication) under specific conditions:

- No new features specific to 11.4 (e.g., new JSON functions, `UUID` data type) are used in DML or DDL.
- The variable `binlog_alter_two_phase` must be set to `0` (default) on the 11.4 Primary.

Step 4

System-Versioned Tables Conversion

If using System-Versioned Tables, the `row_end` column format must be updated to support the extended `TIMESTAMP` range (up to year 2106).

MARIADB-DUMP

Use the new `--update-history` option with `mariadb-dump` to convert `row_end` values during export.

IN-PLACE

Use `ALTER TABLE` to convert the tables after upgrade.

```
ALTER TABLE my_table FORCE;
```

Upgrade from MariaDB Community Server to MariaDB Enterprise Server 11.4

These instructions detail the **upgrade** from **MariaDB Community Server** to **MariaDB Enterprise Server 11.4** on a range of supported Operating Systems.

When MariaDB Enterprise Server is upgraded, the old version needs to be uninstalled, and the new version needs to be installed.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup prior to upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup.

   On MariaDB Community Server 10.4 and later:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Community Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the backup operation.

2. The backup must be prepared.

   On MariaDB Community Server 10.4 and later:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Community Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Audit Plugin Considerations

If you have the MariaDB Audit Plugin installed and if you are upgrading to MariaDB Enterprise Server 10.4 or later, then the audit plugin should be removed prior to the upgrade to prevent conflict with the MariaDB Enterprise Audit Plugin that is present in MariaDB Enterprise Server 10.4 or later.

It can be removed by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

And if you load the plugin in a configuration file using the `plugin_load_add` option, then the option should also be removed.

The MariaDB Enterprise Audit Plugin will automatically be installed after installing MariaDB Enterprise Server 10.4 or later.

Convert InnoDB Row Format

MariaDB Enterprise Server 11.4 changes the `COMPRESSED` row format to read-only. Before upgrading, modify any compressed InnoDB tables to use the `DYNAMIC` row format.

1. Use the `information\_schema.INNODB\_SYS\_TABLES` to identify any InnoDB tables that use the `COMPRESSED` row format:

```
SELECT NAME, ROW_FORMAT
FROM information_schema.INNODB_SYS_TABLES
WHERE NAME NOT LIKE 'SYS_%'
   AND ROW_FORMAT = 'COMPRESSED';
```

2. Execute an ALTER TABLE statement for each table, changing its row format from `COMPRESSED` to `DYNAMIC`:

```
ALTER TABLE accounts.hq_sales
ROW_FORMAT = DYNAMIC
PAGE_COMPRESSED = 1;
```

Uninstall the Old Version

When upgrading to MariaDB Enterprise Server, it is necessary to remove the existing installation of MariaDB Community Server, before installing MariaDB Enterprise Server. Otherwise, the package manager will refuse to install MariaDB Enterprise Server.

Stop the MariaDB Server Process

Before the old version can be uninstalled, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to `1`:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

```
XA RECOVER;
```

   Commit or rollback any open XA transactions before stopping the node for upgrade.

3. Stop the server process:

   For distributions that use systemd (most supported OSes), you can manage the Server process using the `systemctl` command:

```
$ sudo systemctl stop mariadb
```

UNINSTALL VIA YUM

Uninstall via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

```
$ sudo yum remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications:

2. Uninstall the Galera package as well.

   The name of the package depends on the specific version of MariaDB Community Server.

   When upgrading from MariaDB Community Server 10.4 or later, the package is called `galera-4`:

   ```
   $ sudo yum remove galera-4
   ```

   When upgrading from MariaDB Community Server 10.3 or earlier, the package is called `galera`:

   ```
   $ sudo yum remove galera
   ```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

   ```
   $ rpm --query --all | grep -i -E "mariadb|galera"
   ```

UNINSTALL VIA APT

Uninstall via APT (Debian, Ubuntu)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

   ```
   $ sudo apt-get remove "mariadb-*"
   ```

   Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well.

   The name of the package depends on the specific version of MariaDB Community Server.

   When upgrading from MariaDB Community Server 10.4 or later, the package is called `galera-4`:

   ```
   $ sudo apt remove galera-4
   ```

   When upgrading from MariaDB Community Server 10.3 or earlier, the package is called `galera-3`:

   ```
   $ sudo apt remove galera-3
   ```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

   ```
   $ apt list --installed | grep -i -E "mariadb|galera"
   ```

UNINSTALL VIA ZYPP

Uninstall via ZYpp (SLES)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

   ```
   $ sudo zypper remove "MariaDB-*"
   ```

   Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well.

   The name of the package depends on the specific version of MariaDB Community Server.

   When upgrading from MariaDB Community Server 10.4 or later, the package is called `galera-4`:

   ```
   $ sudo zypper remove galera-4
   ```

   When upgrading from MariaDB Community Server 10.3 or earlier, the package is called `galera`:

   ```
   $ sudo zypper remove galera
   ```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

   ```
   $ rpm --query --all | grep -i -E "mariadb|galera"
   ```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

INSTALL VIA YUM

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure YUM package repositories:

   ```
   $ sudo yum install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="11.4"
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo yum install MariaDB-server MariaDB-backup
   ```

   Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

   Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

INSTALL VIA APT

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the APT package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure APT package repositories:

   ```
   $ sudo apt install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="11.4"
   ```

   ```
   $ sudo apt update
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo apt install mariadb-server mariadb-backup
   ```

   Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

   Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

INSTALL VIA ZYPP

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the ZYpp package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions

reference `11.4`.

To configure ZYpp package repositories:

```
$ sudo zypper install curl
```

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="11.4"
```

1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo zypper install MariaDB-server MariaDB-backup
   ```

   Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

   Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Configuration

For platforms that use YUM or ZYpp as a package manager:

MariaDB Community Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back. For example, to move `server.cnf` back in place:

```
$ sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
$ sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use systemd, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called mariadb-upgrade in MariaDB Enterprise Server 10.4 and later:

```
$ sudo mariadb-upgrade
```

And the utility is called `mysql\_upgrade` in MariaDB Enterprise Server 10.3 and 10.2:

```
$ sudo mysql_upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account.

   MariaDB Client is called mariadb (ES10.4 and later) or `mysql` (ES10.3 and earlier):

   ```
   $ sudo mariadb
   ```

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   Your MariaDB connection id is 9
   Server version: 11.4.5-3-MariaDB MariaDB Server

   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

   MariaDB [(none)]>
   ```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

   ```
   SHOW GLOBAL VARIABLES LIKE 'version';
   ```

   ```
   +---------------+-----------------+
   | Variable_name | Value           |
   +---------------+-----------------+
   | version       | 11.4.5-3-MariaDB |
   +---------------+-----------------+
   ```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+------------------+
| VERSION()        |
+------------------+
| 11.4.5-3-MariaDB |
+------------------+
```

Upgrade to MariaDB Enterprise Server 10.6

Overview

These instructions detail the **upgrade** from a previous version of **MariaDB Enterprise Server** to **MariaDB Enterprise Server 10.6** on a range of supported Operating Systems.

When MariaDB Enterprise Server is upgraded, the old version needs to be uninstalled, and the new version needs to be installed.

See What's New in MariaDB Enterprise Server 10.6.

Incompatible Changes

Reserved Words

- **`OFFSET`**: This is now a reserved word. If you have tables or columns named `OFFSET`, you must quote them (e.g., `` `OFFSET` ``) in your SQL queries.

Character Sets

- **`utf8` changes**: The `utf8` character set is now an alias for `utf8mb3` (3-byte) by default. If you need 4-byte support (for emojis), ensure your application explicitly uses `utf8mb4`.

Removed Variables

The following variables have been removed. Remove them from `my.cnf` before upgrading:

- **`innodb_checksum_algorithm`**: The `innodb` and `none` options are removed. Use `crc32` or `full_crc32`.
- **`innodb_log_checksums`**: Removed.

- `innodb_undo_logs`: Removed.

Storage Engines

- **TokuDB**: The TokuDB storage engine was disabled in 10.5 and removed in 10.6. Migrating TokuDB tables to InnoDB or MyRocks is required before upgrading.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup before upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup. On MariaDB Enterprise Server 10.6 and later:

```
sudo mariadb-backup --backup \
      --user=mariadb-backup_user \
      --password=mariadb-backup_passwd \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the backup operation.

2. The backup must be prepared. On the MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-backup --prepare \
      --target-dir=/data/backup/preupgrade_backup
```

Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Audit Plugin Considerations

If you have the MariaDB Audit Plugin installed and are upgrading from MariaDB Enterprise Server 10.2 or 10.3, the audit plugin should be removed prior to the upgrade to prevent conflicts with the MariaDB Enterprise Audit Plugin, which MariaDB Enterprise Audit Plugin that is present in MariaDB Enterprise Server 10.4 or later. It can be removed by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

And if you load the plugin in a configuration file using the `plugin\_load\_add` option, then the option should also be removed. The MariaDB Enterprise Audit Plugin will automatically be installed after installing MariaDB Enterprise Server 10.4 or later.

Uninstall the Old Version

When upgrading to a new major release of MariaDB Enterprise Server, it is necessary to remove the existing installation of MariaDB Enterprise Server before installing the new version of MariaDB Enterprise Server. Otherwise, the package manager will refuse to install the new version of MariaDB Enterprise Server.

Stop the MariaDB Server Process

Before the old version can be uninstalled, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to 1:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

```
XA RECOVER;
```

Commit or roll back any open XA transactions before stopping the node for upgrade.

3. Stop the server process: For distributions that use `systemd` (most supported OSes), you can manage the server process using the `systemctl` command:

```
sudo systemctl stop mariadb
```

Uninstall via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo yum remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications:

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called `galera-enterprise-4`:

```
sudo yum remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Uninstall via APT (Debian, Ubuntu)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo apt-get remove "mariadb-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo apt remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
apt list --installed | grep -i -E "mariadb|galera"
```

Uninstall via ZYpp (SLES)

1. Uninstall all of the MariaDB Enterprise Server packages. Note that a wildcard character is used to ensure that all MariaDB Enterprise Server packages are uninstalled:

```
sudo zypper remove "MariaDB-*"
```

Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well. The name of the package depends on the specific version of MariaDB Enterprise Server. When upgrading from MariaDB Enterprise Server 10.4 or later, the package is called galera-enterprise-4:

```
sudo zypper remove galera-enterprise-4
```

3. Before proceeding, verify that all MariaDB Enterprise Server packages are uninstalled. The following command should not return any results:

```
rpm --query --all | grep -i -E "mariadb|galera"
```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

   To configure YUM package repositories:

```
sudo yum install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

> **Note:**
>
> *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo yum install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository. Installable versions of MariaDB Enterprise Server are `11.8 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure APT package repositories:

```
sudo apt install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

Note:

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

```
sudo apt update
```

3. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup galera-enterprise-4
```

4. Installation of additional packages may be required for some plugins. Configure MariaDB. Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token atand substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the ZYpp package repository. Installable versions of MariaDB Enterprise Server are `11.8, 11.4, 10.6, 10.5, 10.4, and 10.3.` Pass the version to install using the `--mariadb-server-version` flag to `mariadb_es_repo_setup`. The following directions reference 11.8.

To configure ZYpp package repositories:

```
sudo zypper install curl
```

```
curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

Note:

Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.

```
chmod +x mariadb_es_repo_setup
```

```
sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

3. Install MariaDB Enterprise Server and package dependencies:

```
sudo zypper install MariaDB-server MariaDB-backup
```

4. Installation of additional packages may be required for some plugins.
5. Configure MariaDB. Installation only loads MariaDB Enterprise Server onto the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Configuration

For platforms that use YUM or ZYpp as a package manager: MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back.

For example, to move `server.cnf` back in place:

```
sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to `start, stop, restart, enable/disable` on boot, and check the status of the Server using the operating system's default process management system.

For distributions that use `systemd`, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called `mariadb-upgrade` in MariaDB Enterprise Server 10.4 and later:

```
sudo mariadb-upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account. MariaDB Client is called `mariadb` (ES 10.4 and later):

```
sudo mariadb
```

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 9
Server version: 10.6.21-17-MariaDB-Enterprise MariaDB Enterprise Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]>
```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

```
SHOW GLOBAL VARIABLES LIKE 'version';
```

```
+---------------+----------------------------+
| Variable_name | Value                      |
+---------------+----------------------------+
| version       | 10.6.21-17-MariaDB-Enterprise |
+---------------+----------------------------+
```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+----------------------------+
| VERSION()                  |
+----------------------------+
| 10.6.21-17-MariaDB-Enterprise |
+----------------------------+
```

This page is: Copyright © 2026 MariaDB. All rights reserved.

Upgrade MariaDB Enterprise Server from 10.6.X to 10.6.Y

These instructions detail a **minor release upgrade** with **MariaDB Enterprise Server 10.6** on a range of supported Operating Systems.

A minor release upgrade is a change from an earlier release of MariaDB Enterprise Server 10.6 to a later release in the same release series.

For example, it would be a minor release upgrade to upgrade from MariaDB Enterprise Server 10.6.20-16 to MariaDB Enterprise Server 10.6.21-17.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup prior to upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup.

   On MariaDB Enterprise Server 10.4 and later:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Enterprise Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the backup operation.

2. The backup must be prepared.

   On MariaDB Enterprise Server 10.4 and later:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   On MariaDB Enterprise Server 10.3 and earlier:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the prepare operation.

3. Backups should be tested before they are trusted.

Stop the MariaDB Server Process

Before the new version can be installed, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to `1`:

   ```
   SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

   ```
   XA RECOVER;
   ```

   Commit or rollback any open XA transactions before stopping the node for upgrade.

3. Stop the server process:

   For distributions that use `systemd` (most supported OSes), you can manage the Server process using the `systemctl` command:

   ```
   $ sudo systemctl stop mariadb
   ```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

> **INSTALL VIA YUM**
>
> **Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)**
>
> 1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
> 2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `10.6`.
>
>   To configure YUM package repositories:
>
>    ```
>    $ sudo yum install curl
>    ```
>
>    ```
>    $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
>    ```
>
>    ```
>    $ echo "${checksum}  mariadb_es_repo_setup" \
>        | sha256sum -c -
>    ```
>
>    ```
>    $ chmod +x mariadb_es_repo_setup
>    ```
>
>    ```
>    $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
>       --mariadb-server-version="10.6"
>    ```
>
>   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*
>
> 3. Update MariaDB Enterprise Server and package dependencies:

```
$ sudo yum update "MariaDB-*" "galera*"
```

INSTALL VIA APT

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `10.6`.

   To configure APT package repositories:

   ```
   $ sudo apt install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="10.6"
   ```

   ```
   $ sudo apt update
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Update MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo apt install --only-upgrade "mariadb-*" "galera*"
   ```

INSTALL VIA ZYPP

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the ZYpp package repository.

   Installable versions of MariaDB Enterprise Server are `11.4`, `10.6`, `10.5`, `10.4`, and `10.3`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `11.4`.

   To configure ZYpp package repositories:

   ```
   $ sudo zypper install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Update MariaDB Enterprise Server and package dependencies:

```
$ sudo zypper update "MariaDB-*" "galera*"
```

Configuration

For platforms that use YUM or ZYpp as a package manager:

MariaDB Enterprise Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mariadb-enterprise.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back. For example, to move `server.cnf` back in place:

```
$ sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
$ sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

Starting the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use systemd, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run this utility to upgrade the data directory.

The utility is called mariadb-upgrade in MariaDB Enterprise Server 10.4 and later:

```
$ sudo mariadb-upgrade
```

And the utility is called mysql_upgrade in MariaDB Enterprise Server 10.3 and 10.2:

```
$ sudo mysql_upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server using MariaDB Client using the `root@localhost` user account.

   MariaDB Client is called mariadb (ES10.4 and later) or `mysql` (ES10.3, ES10.2):

   ```
   $ sudo mariadb
   ```

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   Your MariaDB connection id is 9
   Server version: 10.6.21-17-MariaDB-Enterprise MariaDB Enterprise Server

   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

   MariaDB [(none)]>
   ```

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL STATUS statement:

   ```
   SHOW GLOBAL VARIABLES LIKE 'version';
   ```

   ```
   +---------------+-------------------------------+
   | Variable_name | Value                         |
   +---------------+-------------------------------+
   | version       | 10.6.21-17-MariaDB-Enterprise |
   +---------------+-------------------------------+
   ```

3. You can also verify the server version by calling the VERSION() function:

   ```
   SELECT VERSION();
   ```

   ```
   +-------------------------------+
   | VERSION()                     |
   +-------------------------------+
   | 10.6.21-17-MariaDB-Enterprise |
   +-------------------------------+
   ```

Upgrade from MariaDB Community Server to MariaDB Enterprise Server 10.6

These instructions detail the **upgrade** from **MariaDB Community Server 10.6** to **MariaDB Enterprise Server 10.6** on a range of supported Operating Systems.

> **Warning:**
>
> MariaDB Community Server 10.6 reached its end of life in July 2026 and no longer receives maintenance or security releases. Upgrading to MariaDB Enterprise Server 10.6 lets you stay on the 10.6 release series while moving to a maintained and supported server.

> **Note:**
>
> This page describes the minimal-change path: switching products while staying on the 10.6 release series. The recommended path is to upgrade directly to MariaDB Enterprise Server 11.8, the newest long-term release series, for a longer support runway — see Upgrade from MariaDB Community Server 10.6 to MariaDB Enterprise Server 11.8.

When switching from MariaDB Community Server to MariaDB Enterprise Server, the old version needs to be uninstalled, and the new version needs to be installed.

MariaDB Enterprise Server 10.6 is not identical to MariaDB Community Server 10.6:

- MariaDB Enterprise Server includes features and fixes backported from later MariaDB versions. For details, see What's New in MariaDB Enterprise Server 10.6.
- MariaDB Enterprise Server does not include plugins that are not supported for enterprise use. Before upgrading, review Differences in Available Plugins for Enterprise Server to confirm that the plugins you rely on are available.

Data Backup

Occasionally, issues can be encountered during upgrades. These issues can even potentially corrupt the database's data files, preventing you from easily reverting to the old installation. Therefore, it is generally best to perform a backup prior to upgrading. If an issue is encountered during the upgrade, you can use the backup to restore your MariaDB Server database to the old version. If the upgrade finishes without issue, then the backup can be deleted.

The instructions below show how to perform a backup using MariaDB Backup. For more information about backing up and restoring the database, please see the Recovery Guide.

1. Take a full backup:

   ```
   $ sudo mariadb-backup --backup \
         --user=mariadb-backup_user \
         --password=mariadb-backup_passwd \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the backup operation.

2. Prepare the backup so that it is ready for immediate restoration if required:

   ```
   $ sudo mariadb-backup --prepare \
         --target-dir=/data/backup/preupgrade_backup
   ```

   Confirm successful completion of the prepare operation.

3. Verify that the backup is recoverable by restoring it to a non-production environment before proceeding with the upgrade.

Audit Plugin Considerations

If you have the MariaDB Audit Plugin installed, then the audit plugin should be removed prior to the upgrade to prevent conflict with the MariaDB Enterprise Audit Plugin that is included in MariaDB Enterprise Server 10.6.

The two plugins differ mainly in how audit logging can be filtered:

Capability	MariaDB Audit Plugin	MariaDB Enterprise Audit
Event selection	Global event types (connect, query, table)	Event filters defined per audit filter
Per-user control	Include/exclude user lists	Default and named per-user audit filters
Per-object control	Not available	Object filters for specific databases and tables
Configuration auditing	Not available	Changes to the audit configuration are logged

It can be removed by using the UNINSTALL SONAME statement:

```
UNINSTALL SONAME 'server_audit';
```

And if you load the plugin in a configuration file using the plugin_load_add option — a mariadbd startup option that loads a plugin library when the server starts — then the option should also be removed.

The MariaDB Enterprise Audit Plugin will automatically be installed after installing MariaDB Enterprise Server 10.6.

Uninstall the Old Version

When upgrading to MariaDB Enterprise Server, it is necessary to remove the existing installation of MariaDB Community Server, before installing MariaDB Enterprise Server. Otherwise, the package manager will refuse to install MariaDB Enterprise Server.

Stop the MariaDB Server Process

Before the old version can be uninstalled, we first need to stop the current MariaDB Server process.

1. Set the innodb_fast_shutdown system variable to `1`:

   ```
   SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. Use XA RECOVER to confirm that there are no external XA transactions in a prepared state:

   ```
   XA RECOVER;
   ```

   Commit or rollback any open XA transactions before stopping the node for upgrade.

3. Stop the server process:

   For distributions that use systemd (most supported OSes), you can manage the Server process using the `systemctl` command:

   ```
   $ sudo systemctl stop mariadb
   ```

UNINSTALL VIA YUM

Uninstall via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

   ```
   $ sudo yum remove "MariaDB-*"
   ```

   Be sure to check that this wildcard does not unintentionally refer to any of your custom applications:

2. Uninstall the Galera package as well.

   For MariaDB Community Server 10.6, the package is called `galera-4`:

```
$ sudo yum remove galera-4
```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

```
$ rpm --query --all | grep -i -E "mariadb|galera"
```

UNINSTALL VIA APT

Uninstall via APT (Debian, Ubuntu)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

```
$ sudo apt-get remove "mariadb-*"
```

   Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well.

   For MariaDB Community Server 10.6, the package is called `galera-4`:

```
$ sudo apt remove galera-4
```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

```
$ apt list --installed | grep -i -E "mariadb|galera"
```

UNINSTALL VIA ZYPP

Uninstall via ZYpp (SLES)

1. Uninstall all of the MariaDB Community Server packages. Note that a wildcard character is used to ensure that all MariaDB Community Server packages are uninstalled:

```
$ sudo zypper remove "MariaDB-*"
```

   Be sure to check that this wildcard does not unintentionally refer to any of your custom applications.

2. Uninstall the Galera package as well.

   For MariaDB Community Server 10.6, the package is called `galera-4`:

```
$ sudo zypper remove galera-4
```

3. Before proceeding, verify that all MariaDB Community Server packages are uninstalled. The following command should not return any results:

```
$ rpm --query --all | grep -i -E "mariadb|galera"
```

Install the New Version

MariaDB Corporation provides package repositories for YUM (RHEL, AlmaLinux, CentOS, Rocky Linux), APT (Debian, Ubuntu), and ZYpp (SLES).

Note:

If the server is a node in a Galera Cluster, also install the Enterprise Galera provider package, `galera-enterprise-4`, which replaces MariaDB Community Server's `galera-4` package. Cluster nodes are also upgraded one node at a time — see Upgrading Galera Cluster for the cluster-specific procedure.

INSTALL VIA YUM

Install via YUM (RHEL, AlmaLinux, CentOS, Rocky Linux)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the YUM package repository. Installable versions of MariaDB Enterprise Server are `10.6`, `11.4`, and `11.8`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `10.6`.

   To configure YUM package repositories:

   ```
   $ sudo yum install curl
   ```

   ```
   $ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
   ```

   ```
   $ echo "${checksum}  mariadb_es_repo_setup" \
       | sha256sum -c -
   ```

   ```
   $ chmod +x mariadb_es_repo_setup
   ```

   ```
   $ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
      --mariadb-server-version="10.6"
   ```

   1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo yum install MariaDB-server MariaDB-backup
   ```

   Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

   Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

INSTALL VIA APT

Install via APT (Debian, Ubuntu)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.
2. Configure the APT package repository.

   Installable versions of MariaDB Enterprise Server are `10.6`, `11.4`, and `11.8`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `10.6`.

To configure APT package repositories:

```
$ sudo apt install curl
```

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

```
$ sudo apt update
```

1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

```
$ sudo apt install mariadb-server mariadb-backup
```

Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

INSTALL VIA ZYPP

Install via ZYpp (SLES)

1. Retrieve your Customer Download Token at https://customers.mariadb.com/downloads/token/ and substitute for `CUSTOMER_DOWNLOAD_TOKEN` in the following directions.

2. Configure the ZYpp package repository.

Installable versions of MariaDB Enterprise Server are `10.6`, `11.4`, and `11.8`. Pass the version to install using the `--mariadb-server-version` flag to mariadb_es_repo_setup. The following directions reference `10.6`.

To configure ZYpp package repositories:

```
$ sudo zypper install curl
```

```
$ curl -LsSO https://dlm.mariadb.com/enterprise-release-helpers/mariadb_es_repo_setup
```

```
$ echo "${checksum}  mariadb_es_repo_setup" \
    | sha256sum -c -
```

```
$ chmod +x mariadb_es_repo_setup
```

```
$ sudo ./mariadb_es_repo_setup --token="CUSTOMER_DOWNLOAD_TOKEN" --apply \
   --mariadb-server-version="10.6"
```

1. *Checksums of the various releases of the `mariadb_es_repo_setup` script can be found in the Versions section at the bottom of the MariaDB Package Repository Setup and Usage page. Substitute `${checksum}` in the example above with the latest checksum.*

3. Install MariaDB Enterprise Server and package dependencies:

   ```
   $ sudo zypper install MariaDB-server MariaDB-backup
   ```

   Installation of additional packages may be required for some plugins.

4. Configure MariaDB.

   Installation only loads MariaDB Enterprise Server to the system. MariaDB Enterprise Server requires configuration before the database server is ready for use.

Configuration

For platforms that use YUM or ZYpp as a package manager:

MariaDB Community Server's packages bundle several configuration files:

- `/etc/my.cnf`
- `/etc/my.cnf.d/client.cnf`
- `/etc/my.cnf.d/mysql-clients.cnf`
- `/etc/my.cnf.d/server.cnf`

If your version of any of these configuration files contained any custom edits, then the package manager may save your edited version with the `.rpmsave` extension during the upgrade process. If you want to continue using your version with the custom edits, then you may need to move it back. For example, to move `server.cnf` back in place:

```
$ sudo mv /etc/my.cnf.d/server.cnf /etc/my.cnf.d/server.cnf.original
```

```
$ sudo mv /etc/my.cnf.d/server.cnf.rpmsave /etc/my.cnf.d/server.cnf
```

In addition to the configuration files listed above, MariaDB Enterprise Server installs its own configuration file:

- On platforms that use YUM or ZYpp: `/etc/my.cnf.d/mariadb-enterprise.cnf`
- On platforms that use APT: `/etc/mysql/mariadb.conf.d/mariadb-enterprise.cnf`

This file provides MariaDB Enterprise Server defaults, some of which change behavior compared to a default MariaDB Community Server configuration:

- Only plugins of stable maturity are loaded (`plugin-maturity=stable`).
- The MariaDB Enterprise Audit Plugin is preloaded (with audit logging off by default).
- The simple_password_check plugin is enabled, so new passwords must be at least 8 characters and include a digit, a special character, and both upper- and lowercase letters.
- The InnoDB adaptive hash index is kept disabled (also the default in MariaDB Community Server 10.6).

Do not edit this file directly. To override its settings, add your own options in a separate configuration file whose name sorts later than `mariadb-enterprise.cnf` .

Starting the Server

MariaDB Enterprise Server includes configuration to start, stop, restart, enable/disable on boot, and check the status of the Server using the operating system default process management system.

For distributions that use systemd, you can manage the Server process using the `systemctl` command:

Operation	Command
Start	`sudo systemctl start mariadb`
Stop	`sudo systemctl stop mariadb`
Restart	`sudo systemctl restart mariadb`
Enable during startup	`sudo systemctl enable mariadb`
Disable during startup	`sudo systemctl disable mariadb`
Status	`sudo systemctl status mariadb`

Upgrading the Data Directory

MariaDB Enterprise Server ships with a utility that can be used to identify and correct compatibility issues in the new version. After you upgrade your Server and start the server process, run the mariadb-upgrade utility to upgrade the data directory:

```
$ sudo mariadb-upgrade
```

Testing

When MariaDB Enterprise Server is up and running on your system, you should test that it is working and there weren't any issues during startup.

1. Connect to the server with MariaDB Client using the `root@localhost` user account:

   ```
   $ sudo mariadb
   ```

   ```
   Welcome to the MariaDB monitor.  Commands end with ; or \g.
   Your MariaDB connection id is 9
   Server version: 10.6.28-24-MariaDB-enterprise MariaDB Enterprise Server

   Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

   Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

   MariaDB [(none)]>
   ```

   The `-enterprise` suffix in the version string confirms that you are connected to MariaDB Enterprise Server rather than MariaDB Community Server.

2. You can also verify the server version by checking the value of the version system variable with the SHOW GLOBAL VARIABLES statement:

   ```
   SHOW GLOBAL VARIABLES LIKE 'version';
   ```

   ```
   +---------------+-------------------------------+
   | Variable_name | Value                         |
   +---------------+-------------------------------+
   | version       | 10.6.28-24-MariaDB-enterprise |
   +---------------+-------------------------------+
   ```

3. You can also verify the server version by calling the VERSION() function:

```
SELECT VERSION();
```

```
+------------------------------+
| VERSION()                    |
+------------------------------+
| 10.6.28-24-MariaDB-enterprise |
+------------------------------+
```

Downgrading MariaDB

> **Note:**
>
> Downgrade planning should ideally be taken into consideration before upgrading in settings where data loss cannot be acceptable. This may need setting up replication between versions in advance to enable controlled switching between versions if necessary.

Overview

Downgrading MariaDB is not officially supported between major versions. Downgrades, unlike upgrades, pose a potential risk since the on-disk data format, internal system tables, and storage engine architecture may not be backwards compatible.

However, a downgrade is achievable as long as you plan properly and avoid using any features that are exclusively available to the higher versions.

Before You Begin

If backported features are used with MariaDB Enterprise Server, downgrading after upgrading to a newer maintenance version may not be allowed. For more information, see the release notes for your version of MariaDB Enterprise Server, specifically the **Backports** section of the **What's New** page.

See MariaDB Enterprise Server Considerations.

Before attempting any downgrade, ensure the following factors:

Feature Compatibility

The downgrade will not succeed if any features introduced in the higher version are in use, such as new InnoDB table formats, storage engine behaviors, or system table structures.

Common version-specific features that may prevent downgrading include:

- **Instant ADD/DROP COLUMN** (`ALTER TABLE ALGORITHM=INSTANT`): Introduced across versions 10.3 and 10.4.
- **New InnoDB redo log formats**: Changed across multiple versions 10.2, 10.3, 10.5, 10.8, 11.0.
- `mysql.global_priv` table: Replaced `mysql.user` in MariaDB 10.4; incompatible with 10.3.
- **InnoDB change buffer removal**: MariaDB 11.0 removed it; cannot downgrade to 10.4 or earlier.

See Version-Specific Incompatibilities for the full list.

Configuration Compatibility

If the older version does not support configuration options added or enabled in the current version, downgrading (and replication to a lower version) may fail.

In such circumstances, configuration variables may need to be modified to match the target version's defaults or supported options before proceeding with the downgrade.

Maintenance Releases

Downgrades within the same release series are generally possible, but compatibility should be verified, especially if changes affecting storage formats or system tables are involved. There are relatively few exceptions; for example, MariaDB 10.1.21 fixed a file format bug that prevented downgrading to previous MariaDB 10.1 versions.

Why Major Version Downgrades Break

The main reasons for a major version downgrade failure are:

- **System table schema changes**: As the privilege system improves, the privilege and status tables in the mysql schema change between most major versions.
- **Format changes on on-disk data**: These are less common and generally table-specific, but when they occur (e.g., using Instant add column in MariaDB 10.3), the affected tables cannot be opened in earlier versions.
- **Internal changes to storage engines**: Both MariaDB 10.2 and MariaDB 10.3, for example, introduced new versions of the InnoDB redo log that are not backward-compatible.

Generic Downgrade Process

The following is a general approach to attempting a downgrade with minimal risk. This method, which minimizes downtime and data risk, is similar to the recommended upgrade path: you set up a replica running the target lower version, make sure it replicates well, and then switch to it.

1. Before attempting downgrade process, verify that features exclusive to the higher version are not used.
2. Use `mariadb-dump` to create a full logical backup of your entire database.

```
mariadb-dump --all-databases > dumpfile
```

3. Additionally, back up the `mysql` schema separately, as this is where the majority of version-specific upgrading changes occur.
4. Store both backups securely and verify their readability before proceeding. These backups serve as your recovery path if anything goes wrong.
5. Install MariaDB's target lower version on a separate server or environment. Then, set up the lower-version server as a replica and the current (higher version) server as the primary.
6. Verify replication is working. On the lower version replica, run:

```
SHOW REPLICA STATUS\G
```

5. Once validation is complete:
    1. Stop writes to the current (higher version) server.
    2. Promote the downgraded server to the primary.
    3. Redirect application traffic to the downgraded server.

Restore from Backup (Fallback Method)

If the replica-based method is not possible, the most reliable alternative is to restore from a full backup created in Step 2 of the Generic Downgrade Process.

1. Install a lower version of MariaDB on a clean server.
2. Launch MariaDB, then restore the backup:
3. To update system tables for the previous version, run mariadb-upgrade.

4. Restart MariaDB and check the connectivity of the application.

When used on a clean installation, this method is reliable but involves more downtime than the replica-based approach.

In-Place Downgrade Method

The MariaDB developers have not tested this method, so it is not advised. A lot of things can go wrong. Whenever possible, use the backup-restore or replica-based methods mentioned above.

In general, an in-place downgrade to a previous major version is only allowed if you have not yet executed mariadb-upgrade on the new version.

Note: It is recommended to run mariadb-upgrade after upgrading to ensure security and collation correctness, which limits the available downgrade window.

If you have to attempt an in-place downgrade process, perform the following steps:

1. Shut down MariaDB cleanly. Ensure:
    1. innodb_fast_shutdown≠2.
    2. You use SHUTDOWN command, mariadb-admin shutdown or the operating system official commands, like systemctl stop mariadb.service.
2. Start the old server binary with –skip-privilege-tables to bypass the incompatible privilege tables.
3. Restore the mysql schema tables to the old definitions using `ALTER TABLE`, or drop and recreate them. To find the old definitions, run mariadb-install-db on a temporary data directory, start a temporary server, and use SHOW CREATE TABLE.
4. Execute FLUSH PRIVILEGES to reload the restored privilege tables.

This procedure will **not** work if the table format has changed in an incompatible manner. In this case the affected tables may not be accessible in the earlier version. See Version-Specific Incompatibilities below.

Version-Specific Considerations

> **Warning:**
>
> Many of the examples that follow use outdated MariaDB versions that are currently End of Life (EOL). For production environments, downgrading to EOL versions is not recommended. These examples are provided for reference and to demonstrate potential incompatibilities.

The following is an incomplete list of cases where a table or component cannot be used in an earlier major version. Before proceeding, always check the Release Notes and Changes and Improvements pages for your target version to ensure that there are no additional incompatibilities specific to your version pair.

- MariaDB 11.0 or later
    - A downgrade to MariaDB 10.4 or earlier is not possible, because MDEV-29694 removed the InnoDB change buffer. making the format incompatible.
    - A downgrade to MariaDB 10.5 or later is only possible if innodb_change_buffering=none (the default starting with MDEV-27734).
- MariaDB 10.8 or later
    - The InnoDB redo log file `ib_logfile0` would need to be replaced with a logically equivalent file, or the shutdown LSN written to the `FIL_PAGE_FILE_FLUSH_LSN` field in the system tablespace (see MDEV-27199), or the data may be accessed read-only when using innodb_force_recovery=6.
- MariaDB 10.5 → MariaDB 10.4

    - The InnoDB redo log file `ib_logfile0` must be deleted between a clean shutdown of the 10.5 and a startup of 10.4. This is **not recommended**.

- MariaDB 10.4 → MariaDB 10.3
    - Any InnoDB table where `ALTER TABLE ALGORITHM=INSTANT DROP COLUMN` was used while innodb_instant_alter_column_allowed=add_drop_reorder.
    - Any InnoDB table created or rebuilt while innodb_checksum_algorithm=full_crc32.
    - In MariaDB 10.4, the `mysql.user` table was replaced by the mysql.global_priv table, which may cause problems if one wants to downgrade to 10.3.

- MariaDB 10.3 → MariaDB 10.2
    - Any InnoDB table where `ALTER TABLE…ADD COLUMN` was used (unless innodb_instant_alter_column_allowed=never).
    - A prior shutdown with innodb_fast_shutdown=0 is required in order to empty the undo logs whose format changed in MDEV-12288. Even then, setting innodb_force_recovery=3 may be necessary.

MariaDB Enterprise Server Considerations

MariaDB Enterprise Server may include backported features, which are functionalities from newer versions added to a previous maintenance release. Downgrading to a version without a backport (even within the same release series) might not be feasible if you use a backported feature.

Before downgrading Enterprise Server:

- Review the **Backports section** of the relevant **What's New** page for your current version.
- Check for enabled backported features.

Differences Between MariaDB and Other DBMSs

This page lists *general* differences between MariaDB and other DBMSs (database management systems). For *specific* differences (for instance, between MariaDB and PostgreSQL), refer to the respective pages in this section.

Database vs. Schema

In MariaDB, the terms *schema* and *database* are synonymous and used interchangeable. The `CREATE SCHEMA` statement is a synonym for `CREATE DATABASE`, meaning they create the same object—a container for database objects like tables and views.

MariaDB does not support a distinction between schema and database as seen in other systems like SQL Server or PostgreSQL, where a schema is a logical container within a database. Instead, a database in MariaDB serves as both a namespace and a logical container to separate objects, and it has a default character set and collation that are inherited by its tables.

DDL Export Guide

This page covers DDL[17] export instructions for Oracle Database, Microsoft SQL Server, MySQL, and IBM DB2.

Oracle Database

There are two basic ways of getting a schema from Oracle, with different features and advantages. The instructions here are based on **Oracle 11.2**. In old versions of Oracle, there was no `SCHEMAS` parameter; instead, only a single schema to export was specified with an `OWNER` parameter.

Using Oracle Data Pump

Oracle Data Pump is a tool used for backing up and restoring Oracle contents. The Data Pump commands (`expdp` and `impdp`) are just frontends that instruct the backend to do the actual dump and restore, which means that the output and input is not necessarily in the current directory. There is a default Data Pump destination directory, though.

> **Note:**
>
> Be aware that, in order to get the schema, you cannot just export it. Rather than that, you export what you are looking for, and then use `impdp` to extract an SQL file with the contents that you have dumped.

What this means is that if you are working from a backup, or a dump as it is called in Oracle, created by `expdp`, this method of extracting a schema is useful. There is not a lot of flexibility though.

Here is an example for extracting a schema called *APP*. First we create a dump – this usually must be done by a system user, as access is needed to the export directory mentioned before.

> **Note:**
>
> In Oracle, every user has a schema named the same as the user, and all objects have “owners”.
>
> All schema names are case sensitive.

The first parameter is the login. You log in as `sysdba`, which is a default DBA[18] user authenticated by the operating system, hence no username/password is specified, just a slash (`/`).

```
$ expdp \"/ as sysdba\" SCHEMAS=APP CONTENT=METADATA_ONLY EXCLUDE=STATISTICS DUMPFILE=app.dmpimpdp \"/ as
sysdba\" dumpfile=app.dmp sqlfile=app.sql
```

When run, the progress of the export is shown. When the process ends, it tells you where the export file is placed, which is the default Data Pump directory. In this case, it is `/u01/app/oracle/admin/XE/dpdump/`.

To extract the schema, run the import tool, like this:

```
$ impdp \"/ as sysdba\" dumpfile=app.dmp sqlfile=app.sql
```

The app.sql file in the default Data Pump directory is `/u01/app/oracle/admin/XE/dpdump/app.sql`.

The advantage of this method is that you can work from a backup. The disadvantage is that this method is not very flexible, and all facts on all objects are exported, even things that are not relevant for a migration.

To export all schema data, skip the `SCHEMAS` parameter, and instead add `FULL=Y`, like this:

```
$ expdp \"/ as sysdba\" FULL=Y CONTENT=METADATA_ONLY EXCLUDE=STATISTICS DUMPFILE=app.dmpimpdp \"/ as
sysdba\" dumpfile=app.dmp sqlfile=app.sql
```

To get the DDL for the appropriate objects, use the `impdp` command like above, where you can use the `SCHEMAS` parameter to filter which schemas you are looking for. If you don’t do this, you get the SQL for every object in the Oracle database, including system schemas.

Using dbms_metadata.get_ddl

This method is much more flexible and creates more reasonable output, but it requires a running Oracle database. It uses a built-in PL/SQL package called `dbms_metadata`, where the `get_ddl` function is used to retrieve the DDL for a specific object. There is also a function called `set_transform_param` that is used to pass parameters to the `get_ddl` function.

This method only exports objects relevant for a migration – it does not export Oracle specific objects nor any system owned objects.

A similar operation as with Data Pump can be executed using a script like this – put it in an SQL file called `exp.sql`:

```
# exp.sql
set long 99999999
set pagesize 0
set feedback off
set echo off
set heading off
SET TRIMSPOOL ON

BEGIN
   dbms_metadata.set_transform_param(dbms_metadata.session_transform, 'PRETTY', TRUE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform, 'TABLESPACE', FALSE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform, 'SQLTERMINATOR', TRUE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform, 'SEGMENT_ATTRIBUTES', FALSE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform, 'FORCE', FALSE);
END;
/

SELECT dbms_metadata.get_ddl(object_type, object_name, user)
  FROM user_objects
  WHERE object_type IN ('TABLE', 'VIEW', 'SEQUENCE', 'FUNCTION', 'PACKAGE',
   'PACKAGE_BODY', 'PROCEDURE', 'INDEX', 'SYNONYM', 'TRIGGER', 'TYPE')
  ORDER BY DECODE(object_type, 'TABLE', 1, 'VIEW', 2, 'INDEX', 3,
    'TRIGGER', 4, 'PACKAGE', 5, 'PACKAGE BODY', 6, 7), object_type;

EXIT
```

When done, run this script through the Oracle `SQL*Plus` utility. You can run that tool as an ordinary user with privileges appropriate to the schema to export. In other words, you do not need DBA privileges. Issue this command:

```
$ sqlplus -S app/app @exp.sql > schema.sql
```

To export all schemas using this method, excluding known system schemas, a slightly different SQL script is used, `expall.sql`:

```
# expall.sql
set long 99999999
set pagesize 50000
set feedback off
set echo off
set heading off
SET TRIMSPOOL ON

BEGIN
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'PRETTY', TRUE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'TABLESPACE', FALSE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'SQLTERMINATOR', TRUE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'SEGMENT_ATTRIBUTES', FALSE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'FORCE', FALSE);
   dbms_metadata.set_transform_param(dbms_metadata.session_transform,
     'CONSTRAINTS_AS_ALTER', TRUE);
END;
/

column OWNER noprint new_value owner_name
break on OWNER skip page
ttitle LEFT '-- Dumping objects for user ' owner_name

SELECT owner, dbms_metadata.get_ddl(object_type, object_name, owner)
  FROM dba_objects
  WHERE object_type IN ('TABLE', 'VIEW', 'SEQUENCE', 'FUNCTION', 'PACKAGE',
     'PACKAGE_BODY', 'PROCEDURE', 'INDEX', 'SYNONYM', 'TRIGGER', 'TYPE')
    AND owner NOT IN('CTXSYS', 'DBSNMP', 'DMSYS', 'MDDATA', 'MDSYS',
      'OLAPSYS', 'ORDSYS', 'ORDPLUGINS', 'OUTLN', 'PUBLIC',
      'SI_INFORMTN_SCHEMA', 'SYS', 'SYSMAN', 'SYSTEM', 'XDB')
    AND temporary = 'N' AND generated = 'N'
    AND (secondary = 'N' OR secondary IS NULL)
  ORDER BY owner, DECODE(object_type, 'TABLE', 1, 'VIEW', 2, 'INDEX', 3,
    'TRIGGER', 4, 'PACKAGE', 5, 'PACKAGE BODY', 6, 7), object_type;

EXIT
```

Run this script as a DBA user:

```
$ sqlplus -S / as sysdba @expall.sql > schema.sql
```

Microsoft SQL Server

For most existing SQL server environments, admin work is done using the GUI tool SQL server Management Studio (SSMS). Use the generate scripts option in SSMS: See this documentation for more details.

Command-line options exist – the SQL server team released a Python-based tool called `mssql-scripter`. Examples of usage are in this document. Full `mssql-scripter` usage options are listed here.

MySQL

Due to the similarities between MySQL and MariaDB, we are able to assess server configurations, too, for different types of `mysqldump` exports (`--all-databases` and `--databases`` *list-of-databases*).

Use `mysqldump` with the connection information to back up all your databases on the existing MySQL Server:

```
mysqldump --user db_user --password \
--host localhost \
--no-data \
--events \
--routines \
--triggers \
-r mydump.sql \
--all-databases
```

You can also choose to export only select databases:

```
mysqldump --user user_db --password \
--host localhost \
--no-data \
--events \
--routines \
--triggers \
-r mydump.sql \
--databases mydb1 mydb2 …
```

Optionally, you can upload your configuration variables to find differences between your MySQL and MariaDB server configurations. Run this command:

```
mysql --user db_user --password --host localhost -e "SHOW GLOBAL VARIABLES;" > variables.log
```

The `variables.log` file can be used for offline comparison between MySQL and MariaDB, to identify any differences.

IBM DB2

Log on to the DB2 server with a user that has `SELECT` privileges on the system catalog tables. In some specific cases, additional grants might be required, such as `SYSADM`, `SYSCTRL`, `SYSMAINT`, `SYSMON`, and `DBADM`. For our specific requirements, the `SELECT` privilege on system catalog tables suffices, though.

> **Note:**
>
> In case of problems, request the DBA to export the schema DDL.

The following list gives examples of various extract options available when extracting DDL from a DB2 server.

- Generate the DDL script for all the objects created by user `foo` in `world` database:
  - `-d` defines the database/alias of the database that you want to extract.
  - `-u` defines the user name you want to export objects of.
  - `-e` is used to export all the possible objects including tables, stored procedures, aliases, triggers, etc.
  - `-o ddl_export.sql` represents the output file.
  - This is the complete command:
    `$ db2look -d world -u foo -e -o ddl_export.sql`
- Generate the DDL script for objects in a particular schema:
  - `-d` defines the database/alias of the database that you want to extract.
  - `-u` defines the user name we want to export objects of.
  - `-z` defines the schema name.
  - `-e` is used to export all the possible objects including tables, stored procedures, aliases, triggers, etc.
  - `-o ddl_export.sql` represents the output file name.
  - This is the complete command:
    `$ db2look -d world -u foo -z globe -e -o ddl_export.sql`

- Generate the DDL script of all the objects regardless of the user they are created with. This is the one most of the exports will be done with, for the sake of completion of the DDL script:
  - `-d` defines the database/alias of the database that you want to extract.
  - `-a` is used to extract objects for all users on the particular database.
  - `-o ddl_export.sql` represents the output file name.
  - `-e` is used to export all the possible objects including tables, stored procedures, aliases, triggers, etc.
  - This is the complete command:
    ```
    $ db2look -d world -a -e -o ddl_export.sql
    ```

The `db2look` command arguments mentioned before work for all DB2 versions starting from DB2 9.7 to 11.5, but for specifics details, refer to the following DB2 pages:

- 9.7 - db2look - DB2 statistics and DDL extraction tool command
- 10.5 - db2look - DB2 statistics and DDL extraction tool command
- 11.5 - db2look - Db2 statistics and DDL extraction tool command

Migrating to MariaDB from MySQL

MariaDB Server is designed to be a high-performance, drop-in replacement for MySQL. Whether you are moving from legacy versions (5.5, 5.6, 5.7) or modern releases (8.0, 8.4 LTS), this section provides the tools and workflows needed for a successful transition.

Evaluate Compatibility

See MySQL to MariaDB Compatibility Matrix.

Before moving data, understand the technical differences between your current MySQL version and your target MariaDB version. Our Compatibility Matrix covers changes in authentication, SQL syntax, and system variables. It's a detailed reference for DBAs and developers.

Choose Your Migration Path

See MySQL to MariaDB Migration: The Master Guide.

The best method for migration depends on your downtime requirements and server architecture. We have consolidated these workflows into a single authoritative guide.

- MySQL to MariaDB Migration: The Master Guide — Step-by-step instructions for:
  - In-Place Upgrades: Fast, same-server binary swaps.
  - Logical Migrations: Safe, cross-server dump and restore.
  - Cloud & RDS Migrations: Specialized paths for managed environments.

Specialized Migration Scenarios

See Migrating Galera Cluster.

See Migrating from MySQL to MariaDB Galera Cluster (Node-by-Node In-Place).

Guides for migrating MySQL Galera Cluster to MariaDB Galera Cluster.

MySQL to MariaDB Migration: The Master Guide

> **Note:**
>
> **Environment Scope**
>
> This guide focuses on **migrations within Linux-based environments** (RHEL/CentOS/Alma, Debian/Ubuntu, etc.), as these represent the vast majority of production MySQL and MariaDB deployments.

Preparation

Pre-Migration Checklist

Before touching the production server, verify these requirements:

- Version Target: Identify your destination.
- *Coming from MySQL 5.7?* MariaDB 10.11 LTS or 11.8 LTS are safe harbors with the longest remaining support runways.
- *Coming from MySQL 8.0/8.4?* MariaDB 11.8 LTS or the new 12.3 LTS are recommended. These versions have the most modern feature parity required for 8.x-era applications.
- Compatibility Check: Review the MySQL to MariaDB Compatibility Matrix for potential high-impact differences in authentication and SQL syntax.

Mandatory Backup

Never start a migration without two types of backups:

1. Physical/Binary Backup: A copy of the `/var/lib/mysql` directory (while the server is stopped). This allows for the fastest “undo” if the binary swap fails.
2. Logical Backup: A full dump of your data.
   Use the MySQL `mysqldump` program, not MariaDB’s `mariadb-dump`, because the latter hasn’t been extensively tested against MySQL.
   Don’t dump `--all-databases`, because that would include the MySQL system databases, which are different from the MariaDB ones – loading them would fail on data import. Instead, specify which databases to export as arguments to `--databases`.

   ```
   # The Universal Master Dump Command
   mysqldump --user=root --password --databases db1 db2 ... \
   --single-transaction --routines --events \
   --triggers --hex-blob > migration_dump.sql
   ```

Porting Users and Privileges

Standard data dumps often fail to capture complex user permissions correctly when moving from MySQL 8.0+. Instead of migrating the entire `mysql` system database, use these scripts on your MySQL source server to generate the exact SQL commands needed to recreate your users and their permissions on MariaDB.

Creating Users on MariaDB

The following SQL can be used to generate CREATE USER statements with a default password that can be executed on MariaDB. It does the following:

- Authentication method mysql_native_password – the script supports passwords porting.
- Authentication method caching_sha2_password or authentication string is `NULL` – passwords are reset to default with expiry.

The PARSEC authentication plugin is intended to be the default in a future release, hence it is recommended to use this during user migration.

```
SELECT
    CASE
        WHEN plugin = 'mysql_native_password'
             AND authentication_string IS NOT NULL
             AND authentication_string <> ''
        THEN CONCAT(
            'CREATE USER IF NOT EXISTS ''', user, '''@''', host,
            ''' IDENTIFIED VIA mysql_native_password USING ''',
            authentication_string, ''';'
        )

        WHEN plugin = 'mysql_native_password'
             AND (authentication_string IS NULL OR authentication_string = '')
        THEN CONCAT(
            'CREATE USER IF NOT EXISTS ''', user, '''@''', host,
            ''' IDENTIFIED BY ''Welcome@123'' PASSWORD EXPIRE; ',
            '-- no source hash available'
        )

        WHEN plugin IN ('caching_sha2_password', 'sha256_password')
        THEN CONCAT(
            'CREATE USER IF NOT EXISTS ''', user, '''@''', host,
            ''' IDENTIFIED BY ''Welcome@123'' PASSWORD EXPIRE; ',
            '-- original plugin: ', plugin
        )

        ELSE CONCAT(
            '-- SKIPPED unsupported plugin for ''', user, '''@''', host,
            ''': ', COALESCE(plugin, 'NULL')
        )
    END AS migration_sql
FROM mysql.user
WHERE user NOT IN ('mysql.sys','mysql.session','mysql.infoschema','root');
```

Copying User Privileges to MariaDB

Use the following SQL to generate user privilege statements for execution in MariaDB from MySQL.

Privileges covered are:

- Global privileges
- Database privileges
- Table privileges
- Procedure privileges

> **Note:**
>
> The SQL may vary depending on the version of MySQL you're coming from.

```
SET SESSION group_concat_max_len = 1000000;

SELECT '-- GLOBAL PRIVILEGES' AS '';

SELECT CONCAT(
'GRANT ',
TRIM(TRAILING ',' FROM CONCAT(
IF(Select_priv='Y','SELECT,',''),
IF(Insert_priv='Y','INSERT,',''),
IF(Update_priv='Y','UPDATE,',''),
IF(Delete_priv='Y','DELETE,',''),
IF(Create_priv='Y','CREATE,',''),

SELECT '-- PROCEDURE PRIVILEGES' AS '';

SELECT CONCAT(
'GRANT ', Proc_priv,
' ON PROCEDURE `', Db, '`.`', Routine_name,
'` TO ''', User, '''@''', Host, ''';'
)
FROM mysql.procs_priv;
```

Proactive SQL Validation

If your application is mission-critical:

- Enable the General Query Log on your MySQL server for a period of time to capture real-world traffic.
- Replay those queries against a MariaDB test instance.
- Check the MariaDB error log for any “Syntax Error” or “Unknown Function” messages. This prevents surprises on migration night.

Step by Step Migration Procedure

Logical migration (dump and restore) is the gold standard for safety. It is the best choice if you are moving to a new server, a different Linux distribution, or a cloud-managed environment.

By exporting the data into an SQL script, you effectively “filter” out any binary-level incompatibilities between MySQL and MariaDB.

A logical migration involves exporting your data into a text-based SQL file (a “dump”) and importing it into a fresh MariaDB instance (“restore”). This is the safest way to ensure data integrity, as it completely recreates your tables and indexes in the MariaDB format.

> **Step 1**
>
> **Export Data from MySQL**
>
> On your existing MySQL server, create a complete dump of all databases, including stored procedures, triggers, and events. (Note this is the same dump command used in the Preparation step, so you can use that one instead of re-creating it.)
>
> ```
> # The Universal Master Dump Command
> mysqldump --user=root --password --databases db1 db2 ... \
> --single-transaction --routines --events \
> --triggers --hex-blob > migration_dump.sql
> ```
>
> - `--single-transaction` : Ensures a consistent backup without locking your tables (for InnoDB).
> - `--hex-blob` : Properly handles binary data like images or encrypted strings.
> - `--routines` and `--events` ensures that the “logic” of the database moves, not just the “rows”.

> **Step 2**
>
> **Prepare the MariaDB Environment**
>
> On your new server, install MariaDB using the Installation Guide for MariaDB Enterprise Server or the Installation Guide for MariaDB Community Server.
>
> Before importing, ensure your MariaDB configuration (`my.cnf`) has enough resources to handle a large import.
>
> - `max_allowed_packet` : Set this to at least `64M` or higher if you have large `BLOB` columns.
> - `innodb_buffer_pool_size` : Temporarily increase this to 70-80% of available RAM to speed up index creation.

> **Step 3**
>
> **Import Data into MariaDB**
>
> Transfer your `mysql_full_dump.sql` file to the new server and run the import:
>
> ```
> # Import the data
> mariadb -u root -p < mysql_full_dump.sql
> ```

Alternative: Direct Network Streaming (The Pipe Method)

If you have limited disk space or a high-speed network connection between your servers, you can “stream” the data directly from the MySQL source to the MariaDB target. This avoids creating a large intermediate `.sql` file on your local disk.

> **Warning:**
>
> Streaming can take a long time for large databases. If it is aborted for any reason (like network timeout), it usually cannot be resumed. This means you’d have to start again from the beginning.

```
mysqldump --user=root --password --databases db1 db2 ... \
--single-transaction --routines --events \
--triggers --hex-blob | mariadb --host=new_server_ip --user=root --password
```

> Pro Tip: To monitor the progress of your transfer in real-time, install the `pv` (Pipe Viewer) utility and insert it into the command: `mysqldump ... | pv | mariadb ...`

Verification and Optimization

Once your data is moved (via either method), complete these three steps to ensure your new server is running at peak performance.

> **Step 1**
>
> **Rebuild Optimizer Statistics**
>
> MariaDB uses a sophisticated cost-based optimizer that may differ from MySQL’s. To ensure your queries use the most efficient execution plans, force a fresh analysis of all tables:
>
> ```
> # Run ANALYZE TABLE on every table in every database to refresh statistics
> mariadb-check -u root -p --analyze --all-databases
> ```
>
> This makes the difference between a migration that “works” and a migration that “works fast”.

Step 2

Character Set & Collation Validation

Ensure your server and your applications agree on the character set and collation to use.

If you notice unexpected behavior or performance drops in specific queries, verify your collations:

```
-- Check for collation issues in your migrated database
SHOW GLOBAL VARIABLES LIKE 'collation%';
SHOW  VARIABLES LIKE 'collation%';
SELECT table_schema, table_name, column_name, collation_name FROM information_schema.columns WHERE
collation_name IS NOT NULL and table_schema not
in('information_schema','performance_schema','mysql','sys') ORDER BY table_schema, table_name;
```

Check if you have queries that may lead to a mismatch error when joining 2 columns with different collations. Alter your table or database to use the same collation across all your databases. See ALTER TABLE and ALTER DATABASE for details.

> **Note:**
>
> **Why this matters**
>
> If a user has one table set to the old MySQL default and another table set to a MariaDB default, a `JOIN` between them might suddenly stop using indexes because of the "collation mismatch." The above snippet gives you the SQL command to find the problem immediately.

Step 3

Check the Error Log

Check for any "Deprecated Variable" or "Ignored Option" warnings that might have appeared during startup.

```
sudo tail -f /var/log/mysql/error.log | grep -e 'Deprecated|Ignored'
```

Step 4

Application Smoke Test

Verify that your application can connect. Pay special attention to character sets: Ensure your apps and the server agree on `utf8mb4` or whatever character set you choose.

Step 5

Security Hardening: Transition to PARSEC

For migrations to MariaDB 11.8 LTS and later, consider transitioning your users to the PARSEC authentication plugin. While `mysql_native_password` and `caching_sha2_password` are supported for compatibility, PARSEC is the modern successor designed for significantly stronger password hashing and better long-term security.

```
-- Example: Update a user to use PARSEC
ALTER USER 'app_user'@'localhost' IDENTIFIED VIA parsec USING PASSWORD('secure_password');
```

Troubleshooting & FAQ

Even with careful preparation, migrations can encounter specific hurdles. Here are the most common issues and how to resolve them.

Common Troubleshooting Scenarios

Issue	Likely Cause	Resolution
“Table ‘mysql.user’ doesn’t exist”	Missing `mariadb-upgrade` step.	The system tables must be converted. Run `sudo mariadb-upgrade -u root -p` immediately after starting the service.
Replication fails with “relay log” errors.	GTID Incompatibility.	MariaDB cannot use MySQL GTIDs. You must switch to position-based replication (File and Position) to link the two systems.
Slow queries after migration.	Outdated optimizer statistics.	MariaDB’s optimizer needs fresh data. Run `ANALYZE TABLE` on all large tables, or use `mariadb-check --analyze --all-databases`.

Frequently Asked Questions

Q: Can I go back to MySQL if the MariaDB migration fails? A: Yes, provided you took a physical backup (the `/var/lib/mysql` folder) before running `mariadb-upgrade`. Once `mariadb-upgrade` has modified the system tables, you cannot simply point MySQL binaries back at that data directory.

Q: Do I need to change my application’s client libraries? A: Usually, no. MariaDB is protocol-compatible with MySQL. Your existing MySQL connectors (JDBC, PHP PDO, Python mysqlclient) will continue to work. However, for the best performance and features (like IAM authentication), switching to the official MariaDB Connectors is recommended.

Q: What about the JSON data type? A: Your `JSON` columns will be treated as `LONGTEXT` with a `CHECK` constraint. Your queries using `JSON_EXTRACT()` will continue to work exactly as they did in MySQL.

Q: Is MariaDB 11.8 compatible with MySQL 8.4? A: Yes, for standard SQL and data. However, MySQL 8.4 removed many “legacy” behaviors that MariaDB still supports.

Q: Can I perform an in-place upgrade (binary swap)? A: No. MariaDB stores metadata (table structures etc.) in individual `.frm` files. In contrast, MySQL removed `.frm` files in MySQL 8.0, replacing it with a global data dictionary. If you stop a MySQL 8.0/8.4 server and point MariaDB binaries at that data directory, MariaDB will look for `.frm` files to understand what tables exist. Since those files no longer exist in MySQL 8.0+, MariaDB will see an “empty” data directory or throw critical errors. It has no way to read MySQL’s new internal dictionary tables.

Q: Can I perform an in-place upgrade for MySQL versions prior to 5.7? After all, those versions still use `.frm` files instead of a global data dictionary. A: In theory, that’s possible, but in practice, you shouldn’t do that either. Those old MySQL versions are built for operating systems like RHEL 6 which are out of support. You’d end up on an unsupported version of the operating system, on which you shouldn’t install supported versions of MariaDB.

MySQL to MariaDB Compatibility Matrix

Introduction & Executive Summary

MariaDB Server was originally designed as a drop-in replacement for MySQL, maintaining high compatibility across library binary protocols, file structures, and APIs. For most applications, moving from MySQL to MariaDB is a straightforward process that requires minimal changes to your code or configuration.

However, as both projects have evolved—particularly with the release of MySQL 8.0, the latest MySQL 8.4 LTS, and MariaDB 10.11/11.4 LTS—they have introduced unique features and default behaviors. While MariaDB often maintains support for "legacy" MySQL behaviors for compatibility, MySQL 8.4 has moved to aggressively remove them. This guide highlights the essential differences you must understand to ensure a seamless transition.

The TL;DR of MySQL to MariaDB Migration

If you are migrating from MySQL 8.0 or 8.4 LTS to a modern version of MariaDB, these are the four "deal-breaker" areas where you are most likely to encounter friction:

Authentication & Security

MySQL 8.4 has accelerated the push toward `caching_sha2_password`. Notably, the older `mysql_native_password` plugin is now disabled by default in MySQL 8.4 and requires explicit configuration to enable. MariaDB continues to support and often default to `mysql_native_password` or `unix_socket`.

- Action: Check your client connector versions. When moving from 8.4 to MariaDB, you may need to re-enable or transition user accounts back to `mysql_native_password` or `ed25519`.

Feature & Variable Removals

A key difference in MySQL 8.4 is the removal of many system variables and syntax options that were deprecated in 8.0. MariaDB often retains these for backward compatibility.

- Action: If you have optimized your configuration specifically for 8.4 by removing "removed" variables, MariaDB will likely accept them, but it may also still support the older variants you previously used in MySQL 5.7 or 8.0.

Global Transaction IDs

MariaDB and MySQL use entirely different formats for GTIDs. In MySQL 8.4, replication syntax has been further modernized (e.g., removal of `MASTER` in favor of `SOURCE` keywords). MariaDB maintains its own unique GTID structure (`DomainID:ServerID:Sequence`).

- Action: You cannot "mix and match" GTID replication directly. Plan to use position-based replication if running a hybrid environment during your migration.

Data Types & JSON Evolution

Both systems have diverged in how they handle complex data. MySQL 8.0 and 8.4 use a native binary format for JSON, optimized for their internal engine. MariaDB treats JSON as an alias for `LONGTEXT` with `CHECK` constraints.

- Action: While SQL-level JSON functions are highly compatible, performance and storage characteristics differ. Test any application logic that relies on high-speed JSON attribute extraction.

How to use this Matrix

The table below provides a granular breakdown of these differences. We recommend focusing on the “High Impact” items first, as these are the most likely to affect your application’s ability to connect or execute queries immediately after the migration.

> Target Version Tip: If you are migrating from MySQL 8.4 LTS, the most logical targets are MariaDB 10.11 LTS or MariaDB 11.4 LTS to ensure you are moving from one stable long-term environment to another.

> **Note:**
>
> **Key changes from the 8.4 Nutshell you should keep in mind**
>
> - Authentication: The fact that `mysql_native_password` is now “off” by default in 8.4 is a huge point of divergence. Most MariaDB installs still rely on it.
> - Syntax: 8.4 officially removed `SET OPTION`, the `LOW_PRIORITY` prefix for some statements, and various SSL variables. If a user’s app was updated to work with 8.4, it’s “cleaner” but might be using syntax that MariaDB handles differently.
> - Default Changes: Some InnoDB defaults changed in 8.4 that might not match MariaDB’s defaults.

Authentication & Security

Component	MySQL 8.0 / 8.4 Behavior	MariaDB Behavior	Migration Impact
Default Authentication Plugin	`caching_sha2_password` (MySQL 8.4 requires explicit config to even *enable* native password).	`mysql_native_password` or `unix_socket`.	High. New MySQL users cannot connect to MariaDB without altering the account or updating the client.
Connection Security	`REQUIRE SSL` is common.	Supports SSL/TLS but syntax for specific ciphers can vary.	Medium. Review `GRANT` statements for SSL requirements.
Password Complexity	`validate_password` component.	`simple_password_check` or `cracklib_password_check` plugins.	Low. Logic is similar, but plugin names and variables differ.
User Locking	Supports `ACCOUNT LOCK` / `UNLOCK`.	Supports `ACCOUNT LOCK` / `UNLOCK` (10.4.2+).	None. Highly compatible syntax.

SQL Syntax & Data Types

Component	MySQL 8.0 / 8.4 Behavior	MariaDB Behavior	Migration Impact
JSON Support	Native binary format (`JSON` type).	Alias for `LONGTEXT` with `CHECK` constraints.	Medium. SQL syntax is compatible, but binary-level storage and some indexing optimizations differ.
Reserved Words	Frequent additions (e.g., `WINDOW`, `EXCEPT`, `INTERSECT` in 8.0+).	Also uses these reserved words, but some unique MariaDB keywords may exist.	Low. Most modern reserved words are now synchronized between both.
Invisible Columns	Supported since 8.0.23.	Supported since 10.3.3.	None. Highly compatible syntax.
Common Table Expr (CTE)	Non-recursive and Recursive support.	Non-recursive and Recursive support.	None. Functionally identical for standard use cases.
Window Functions	Standard support since 8.0.	Standard support since 10.2.	Low. Standard syntax is compatible; specific MySQL-only extensions are rare.

System Variables & Defaults

This section helps the DBA avoid “Unknown variable” errors when they first try to start the MariaDB service using a MySQL configuration file.

Feature / Variable	MySQL 8.0 / 8.4 Defaults	MariaDB Defaults	Migration Impact
Configuration File	Reads `my.cnf` / `my.ini`.	Reads `my.cnf` / `my.ini` and `mariadb.cnf`.	None. MariaDB maintains compatibility with existing MySQL config files.
Removed Variables	Many 5.7 variables removed in 8.4 (e.g., `expire_logs_days`).	Often retains these legacy variables as aliases.	Low. MariaDB is generally more forgiving of “old” variables than MySQL 8.4.
Default Charset	`utf8mb4_0900_ai_ci` (MySQL 8.0+).	`utf8mb4_uca1400_ai_ci` (MariaDB 11.4+).	Medium. Sorting/Collation behavior may differ slightly for modern Unicode characters.
Explicit Defaults	`explicit_defaults_for_timestamp` is `ON`.	`explicit_defaults_for_timestamp` defaults to `OFF` (for legacy compatibility).	Medium. Can cause different behavior for `TIMESTAMP` columns without explicit defaults.

Replication & GTIDs

Feature	MySQL 8.0 / 8.4 Behavior	MariaDB Behavior	Migration Impact
GTID Format	`UUID:Sequence`	`Domain:ServerID:Sequence`	Critical. Formats are incompatible. GTID replication cannot be mixed directly.
Repl. Syntax	Uses `SOURCE` / `REPLICA` (8.0.22+).	Uses `MASTER` and `REPLICA`.	None. MariaDB is bi-lingual regarding replication syntax.
Binary Logging	Defaulted to `ON`.	Defaulted to `ON` in recent versions.	Low. Standard binary log events are generally compatible.

Next Steps

Now that you’ve reviewed the compatibility differences, you are ready to begin the migration.

Proceed to MySQL to MariaDB Migration: The Master Guide for step-by-step instructions on performing an in-place upgrade or a logical migration.

This page is licensed: CC BY-SA / Gnu FDL

Migrating Galera Cluster

This guide covers the migration of a live database from a MySQL Galera Cluster to a MariaDB Galera Cluster. The migration strategy requires setting up a new MariaDB Cluster, then using asynchronous replication to sync it with an existing MySQL Cluster. The method includes a reliable failback route.

> **Note:**
>
> This document focuses on the migration process itself. For detailed comparisons between the two database systems, please refer to Incompatibilities and Feature Differences Between MariaDB and MySQL.

Prerequisites

- **MySQL Server**: A running MySQL Galera Cluster (version 8.0 or 8.4) to migrate.
- **MariaDB Server**: The target MariaDB version that supports Galera Cluster. This guide assumes the latest stable version.
- **`mysqldump`**: A command-line utility by MySQL to create initial database backup.

> **Warning:**
>
> Due to changes in MySQL 8.0+, `mariadb-dump` may not be compatible for this initial step.

- **Root or Sudo Access**: Administrative privileges are required on all servers involved in the migration.

Migration Steps

Step 1

Check for Incompatibilities

> **Warning:**
>
> While MariaDB maintains a high degree of compatibility with MySQL, it is crucial to review any differences that could impact your applications.

- **Version Compatibility**: Select a MariaDB version compatible with your MySQL version for replication.
- **Feature Differences**: Review the Incompatibilities and Feature Differences to identify any deprecated features or changes in system tables, user accounts, and authentication that might affect your setup.

Replication Compatibility

MySQL Version	Compatible MariaDB Version
5.7	10.2 and newer
8.0	10.6.21, 10.11.11, 11.4.5, 11.7.2 and newer

For more details, see MySQL to MariaDB Replication Compatibility.

Step 2

Install and Configure a New MariaDB Galera Cluster

Set up a new, empty MariaDB Galera Cluster that will become the target for the migration.

1. **Install MariaDB Server and Galera Provider**

Install MariaDB Server package and Galera wsrep provider library on each node of the new cluster. Refer Install and Upgrade MariaDB for detailed instructions.

2. **Configure Each MariaDB Node**

Create a configuration file at `/etc/mysql/conf.d/galera.cnf` on each node. The configuration will be mostly identical across nodes, except for node-specific details like `wsrep_node_name` and `wsrep_node_address`.

Example `galera.cnf`:

```
[mysqld]
# MariaDB settings
binlog_format=ROW
default_storage_engine=InnoDB
innodb_autoinc_lock_mode=2
bind-address=0.0.0.0

# Galera Provider Configuration
wsrep_on=ON
wsrep_provider=/usr/lib/galera/libgalera_smm.so # Adjust path if necessary

# Galera Cluster Configuration
wsrep_cluster_name="new_mariadb_cluster"
wsrep_cluster_address="gcomm://node1_ip,node2_ip,node3_ip"

# Node-specific Configuration
wsrep_node_name="mariadb_node1"
wsrep_node_address="node1_ip"

# SST Configuration
wsrep_sst_method=mariadb-backup
```

Note:

It is recommended to set `wsrep_sst_method` on all nodes to ensure consistency during State Snapshot Transfers(SST).

Step 3

Back Up the MySQL Database

A full logical backup of the MySQL database is required to seed the new MariaDB Cluster.

1. **Enable Binary Logging on MySQL**

   Asynchronous replication requires the binary log to be enabled on the MySQL source. If not enabled, enable it on at least one node in your MySQL cluster.

   1. **Edit `my.cnf`** : In the `[mysqld]` section of your MySQL configuration file, add `log-bin=mysql-bin` .
   2. **Restart MySQL**: A server restart is required for the change to take effect.

> **Important:**
>
> Restarting MySQL will cause a brief outage for the node.

2. **Create the Backup with `mysqldump`**

Use `mysqldump` from the source MySQL server to create a full backup. Using `--all-databases` and `--master-data` will include all databases and the binary log position needed to start replication.

```
mysqldump --user=backup_user --password --all-databases --master-data=2 > /path/to/backup.sql
```

> **Note:**
>
> This above command generates a backup file and logs the source's binary log file name and position in the output.

Step 4

Bootstrap the MariaDB Cluster and Restore Data

Start the first node of the MariaDB cluster and load the MySQL backup.

1. **Bootstrap the First Node**

Start the first MariaDB node with the `--wsrep-new-cluster` option. This initializes the cluster.

```
sudo galera_new_cluster
```

2. **Load the Backup File**

Transfer the `backup.sql` file to the first MariaDB node and import it:

```
mariadb -u root -p < /path/to/backup.sql
```

3. **Start Subsequent Nodes**

Start the MariaDB service normally on the remaining nodes. They will connect to the first node, and a State Snapshot Transfer (SST) will automatically sync their data.

```
sudo systemctl start mariadb
```

4. **Verify the Cluster**

Connect to any node and check the cluster size to ensure all nodes have joined successfully.

```
SHOW STATUS LIKE 'wsrep_cluster_size';
```

> **Note:**
>
> Cluster size should match the number of nodes in your cluster.

Step 5

Set Up Asynchronous Replication

Configure one of the MariaDB nodes to act as a replica of the source MySQL cluster.

1. **Create a Replication User on MySQL**

On the MySQL source node where binlogging is enabled, create a dedicated user for replication.

```
CREATE USER 'repl_user'@'mariadb_node_ip' IDENTIFIED BY 'your_password';
GRANT REPLICATION SLAVE ON *.* TO 'repl_user'@'mariadb_node_ip';
```

2. **Configure the MariaDB Replica**

On one of the MariaDB nodes, configure and start the replication process. Use the binary log file and position noted from the `mysqldump` output (`MASTER_LOG_FILE` and `MASTER_LOG_POS`) or use GTID-based replication.

```
CHANGE MASTER TO
  MASTER_HOST='mysql_source_ip',
  MASTER_PORT=3306,
  MASTER_USER='repl_user',
  MASTER_PASSWORD='your_password',
  MASTER_USE_GTID=slave_pos;

START SLAVE;
```

> **Step 6**
>
> **Monitor and Failover**
>
> With replication running, the MariaDB cluster will catch up with any changes made to the MySQL cluster since the backup was taken.
>
> 1. **Monitor Replication Lag**
>
> Check the replica status on the MariaDB node to ensure it is synchronized.
>
> ```
> SHOW SLAVE STATUS\G
> ```
>
> Ensure the following conditions are met on the replica:
>
> - `Slave_IO_Running: Yes`
> - `Slave_SQL_Running: Yes`
> - `Seconds_Behind_Master: 0`
>
> A `Seconds_Behind_Master` value of `0` indicates the replica is completely synchronized.
>
> 2. **Perform the Failover**
>
> Once the MariaDB cluster is fully synchronized, follow these steps:
>
> 1. **Stop Application Traffic:** Cease traffic to the MySQL cluster.
> 2. **Verify Synchronization:** Confirm the MariaDB replica has processed all events from the MySQL binary log.
> 3. **Promote MariaDB:**
>   - Stop replication on the MariaDB node using `STOP SLAVE;`.
>   - Update your application to connect to the MariaDB Galera Cluster.
> 4. **Resume Application Traffic:** Redirect traffic to the MariaDB cluster.
> 5. **Decommission MySQL:** After confirming the application runs smoothly on MariaDB, decommission the MySQL cluster.

Migrating from MySQL to MariaDB Galera Cluster (Node-by-Node In-Place)

> **Warning:**
>
> **Version Requirement**
>
> This guide provides instructions for migrating a **MySQL 8.0 Galera Cluster** to a **MariaDB Galera Cluster 11.4**. Ensure that your systems meet or exceed these version requirements before proceeding. Please refer to the Prerequisites for detailed version information.
>
> The **End-of-Life (EOL)** date for continued maintenance and regular binary releases of MySQL Galera Cluster will be **September 30, 2026**.

This guide outlines the procedure for migrating a live MySQL Galera Cluster to a MariaDB Galera Cluster. It follows the process for migrating a live MySQL Galera Cluster to a MariaDB Galera Cluster by replacing the binaries on each node sequentially. This “In-Place” method maintains cluster availability during the migration, although the cluster capacity will be reduced while individual nodes are being processed.

Prerequisites

- **Source:** MySQL Galera Cluster 8.0.43-26.4.24 or later.
- **Target:** MariaDB Community Server 11.4 (LTS) or later.

- **Library:** MariaDB Galera library 26.4.24 or latest stable edition.
- **Tools:**
  - `mysqldump` (installed with the server).
  - `mariadb-backup` (installed with MariaDB).
- **Access:** Root access to the operating system and the database.

> **Important:**
>
> **Cluster Backup**
>
> This migration involves uninstalling software and wiping data directories on live nodes. **A full cluster backup (using Xtrabackup or Volume Snapshot) is mandatory before proceeding.**

Incompatibility Check & Data Preparation

> **Warning:**
>
> **Perform these steps on the running MySQL Cluster BEFORE shutting down any nodes.**

Incompatibilities and Feature Differences

MariaDB maintains high levels of compatibility with MySQL, but you still need to check for incompatibilities and feature differences to select the most suitable MariaDB version compatible with your current MySQL server.

While MariaDB and MySQL share a common history, they have diverged significantly. You must “clean” the schema and configurations to ensure data compatibility before the migration begins.

1. Authentication Protocol

MySQL 8.0 defaults to `caching_sha256_password`. MariaDB does not support the `caching_sha256_password` authentication protocol in all released versions (which is cumbersome and not secure for in-house attacks, since clear-text passwords are available inside the server).

Support Status:

- Implemented via MDEV-9804 for version 12.1.1.
- Available in the CS release based on MDEV-37600.
- Already supported in 11.8 Enterprise Server via MENT-2359.
- Available in 11.4 Enterprise Server with the December 2025 release as a rebase of MDEV-37600.

> **Note:**
>
> **For MySQL 8.4 Users**
>
> Ensure `mysql_native_password=ON` is set in your configuration, or you will receive the error: `Plugin 'mysql_native_password' is not loaded`.

You can check which MySQL users are using SHA-256 or caching_sha256_password by executing:

```
SELECT user, plugin FROM mysql.user WHERE plugin LIKE "%sha%";
```

You can change the user to use a protocol compatible with both MySQL and MariaDB with:

```
ALTER USER user_name IDENTIFIED WITH mysql_native_password BY 'new_password';
```

2. JSON Column Conversion

MySQL stores JSON as a native binary type. MariaDB stores JSON as an alias for `LONGTEXT` with constraint checks. Galera replication may break if you attempt to replicate binary JSON objects from MySQL to MariaDB.

Check if you have tables that use the MySQL JSON type:

```
SELECT table_schema, table_name FROM information_schema.COLUMNS
WHERE data_type="JSON";
```

You can convert the JSON column to text with:

```
ALTER TABLE table_name MODIFY json_column LONGTEXT;
```

3. Encryption and Compression

Encryption and compression table options are very different in MySQL compared to MariaDB. Logical dump will naturally de-encrypt/de-compress table contents but syntax used for creating tables is not supported by MariaDB.

For example:

```
CREATE TABLE `t1` (
`c1` int DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci COMPRESSION='lz4'
```

leads to: `ERROR 1911 (HY000) at line 1174: Unknown option 'COMPRESSION'`

Therefore, encrypted/compressed tables need to be de-encrypted/de-compressed before starting the conversion, and then encrypted/compressed again afterwards using MariaDB syntax.

Detect encrypted tables:

```
SELECT table_schema, table_name, create_options FROM information_schema.TABLES WHERE
create_options LIKE "%ENCRYPT%";
```

Detect compressed tables:

```
SELECT table_schema, table_name, create_options FROM information_schema.TABLES WHERE
create_options LIKE "%COMP%";
```

Action: Run `ALTER TABLE` to remove the conflicting **`ENCRYPTION`** and **`COMPRESSION`** attributes. They can be re-enabled using MariaDB syntax after the full migration is complete.

4. General Tablespaces

MariaDB does not support MySQL general tablespaces. In MySQL, these are used to store tables in specific external files rather than the default data directory. During migration, this `TABLESPACE` argument is ignored.

Example Scenario: In MySQL, a user creates a custom tablespace file at a specific path and assigns a table to it:

```
-- MySQL: Creating a tablespace in a custom file location
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/home/jan/galeradb/node1/ts1.ibd' Engine=InnoDB;

-- MySQL: Creating a table assigned to that tablespace
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1;
```

If you examine the table definition in MySQL, you will see the tablespace assignment:

```
mysql> show create table t1;
| t1 | CREATE TABLE `t1` (
 `c1` int NOT NULL,
 PRIMARY KEY (`c1`)
) /*!50100 TABLESPACE `ts1` */ ENGINE=InnoDB ... |
```

Migration Behavior: When this table is migrated to MariaDB (via `mysqldump`), the `TABLESPACE 'ts1'` attribute is ignored.

- **Result:** The table `t1` will be created as a standard file-per-table in the default MariaDB data directory (e.g., `/var/lib/mysql/dbname/t1.ibd`).
- **Loss of Path:** It will **not** use the custom path `/home/jan/galeradb/node1/ts1.ibd`.sq

> **Warning:**
>
> During cluster migration make sure that **no new tablespaces are created** and **no new tables created inside a general tablespaces**.

5. XA Transactions

Ensure no XA transactions are in a `PREPARED` state, as these cannot be migrated cleanly.

```
XA RECOVER; -- Should return an empty set
```

Global Cluster Preparation

> **Note:**
>
> **Perform these steps on the running MySQL Cluster.**

1. Create the SST User (Crucial)

The `mysql.user` system table structure differs between vendors and **will not migrate automatically**. You must create the SST user now so it exists in the data stream before the switch.

```
-- Create user compatible with both engines
CREATE USER 'sst_user'@'localhost' IDENTIFIED WITH mysql_native_password BY 'strong_password';
GRANT ALL PRIVILEGES ON *.* TO 'sst_user'@'localhost';
FLUSH PRIVILEGES;
```

2. Configure InnoDB Settings

Ensure these settings are active on the MySQL cluster.

- **`innodb_file_per_table = 1`**
  - This is the default setting for MySQL and MariaDB. If this is not set, you must use `mysqldump` for the entire migration, as specific recommendations regarding tablespaces will not work.
- **`innodb_flush_log_at_trx_commit = 1`**
  - InnoDB writes the log buffer to the log file and flushes it to disk after every transaction commit. This is the safest option, ensuring no data loss in a crash, though it comes at the cost of slower performance due to frequent disk I/O.

3. Galera Provider Options

- **`gcache.size`**: Should be large enough to avoid SST (State Snapshot Transfer) when a node is temporarily out of the cluster. A larger cache increases the chance of a faster IST (Incremental State Transfer).
  - See: Customizing gcache.size

Migrating the First Node (“The Bridge”)

This is the most complex step. This node will bridge the gap between the MySQL cluster and the new MariaDB environment.

> **Step 1**
>
> **Isolate and Shutdown**
>
> 1. **Remove from Load Balancer:** Ensure no application traffic is hitting this node.
> 2. **Clean Shutdown Prep:**
>
>    ```
>    SET GLOBAL innodb_fast_shutdown = 0;
>    ```
>
> 3. **Stop the Service:**
>
>    ```
>    mysqladmin -u root -p shutdown
>    ```

> **Step 2**
>
> **Swap Binaries & Wipe Data**
>
> 1. **Uninstall MySQL:** Remove all MySQL server and client packages using your OS package manager (e.g., `apt remove`, `dnf remove`).
> 2. **Clean Data Directory:** One way is to move all files under `datadir` to a new directory.
>
>    ```
>    mv /var/lib/mysql /var/lib/mysql_backup_timestamp
>    mkdir /var/lib/mysql
>    chown mysql:mysql /var/lib/mysql
>    ```
>
> 3. **Install MariaDB:** Install `mariadb-server` and `mariadb-backup`.

Step 3

Configure MariaDB (`my.cnf`)

Update the configuration file to work with both MariaDB and MySQL.

Verify Configuration: Before starting the service, verify that your configuration file does not contain unsupported options (such as `regexp-time-limit`).

```
mariadbd --help --verbose > /tmp/log 2>&1
```

Check `/tmp/log` for any errors or warnings about unknown variables and adjust your configuration files if needed.

Required Settings: You **must** add these specific settings for the first node:

```
[galera]
# ... standard galera settings ...

# 1. IGNORE PROTOCOL MISMATCH
# Required to avoid application protocol mismatch messages during migration.
wsrep_provider_options="gcs.check_appl_proto=0;gcache.size=2G"

# 2. USE LOGICAL SST (First Node Only)
# wsrep_sst_method should be set to mysqldump for the first MariaDB node
# to join the MySQL cluster.
wsrep_sst_method=mysqldump

# 3. SST AUTHENTICATION
# Should contain user and password and this user should exist on both
# MySQL and MariaDB databases with sufficient access rights.
wsrep_sst_auth=sst_user:strong_password
```

Step 4

Start and Join

Start the MariaDB service:

```
systemctl start mariadb
```

When initiated, the node connects to the MySQL cluster and automatically triggers a `mysqldump` on a designated MySQL donor node. It then imports the SQL dump stream, effectively reconstructing the database in MariaDB's native format.

Step 5

Post-Join Upgrade

Once the node is `Synced` , run `mariadb-upgrade` to fix system tables.

> **Warning:**
>
> Manually re-create the `sst_user` (and other system users) if `mariadb-upgrade` reports issues, as the `mysql.user` table structure is not fully compatible.

Migrating Subsequent Nodes

Once the first node (Node A) is successfully running MariaDB, you can migrate Node B, Node C, etc.

Step 1

Shutdown and Replace

1. **Set Fast Shutdown:**

   ```
   SET GLOBAL innodb_fast_shutdown = 0;
   ```

   Required because undo/redo log formats may change between versions.

2. **Shutdown:** `mysqladmin -u root -p shutdown`
3. **Wipe & Install:** Uninstall MySQL, Wipe Datadir, Install MariaDB.

Step 2

Configure MariaDB

The configuration differs slightly for subsequent nodes. We switch back to **Physical Backups** for speed.

```
[galera]
# ... standard galera settings ...

# 1. Point to the MariaDB Donor
# After the first MariaDB node has successfully joined, this variable
# should be set on all other nodes to the value of wsrep_node_name
# on the first MariaDB node.
wsrep_sst_donor=Name_of_First_MariaDB_Node

# 2. Use Binary SST
# For other joining nodes, mariabackup value should be used.
wsrep_sst_method=mariabackup
wsrep_sst_auth=sst_user:strong_password

wsrep_provider_options="gcs.check_appl_proto=0"
```

Step 3

Start and Join

Start the service. The node will perform a binary snapshot transfer (`mariabackup`) from the first MariaDB node.

Repeat the above 3 steps for all remaining nodes.

Finalization

Once all nodes are running MariaDB:

1. **Cleanup Config:** Remove `gcs.check_appl_proto=0` and `wsrep_sst_donor` from `my.cnf` on all nodes. Reset `wsrep_sst_method` to `mariabackup` on the first node.
2. **Security:** Run `mariadb-secure-installation` to secure the root account and remove anonymous users.
3. **Features:** Re-enable encryption or compression using MariaDB-supported syntax if required.

Known Issues & Limitations

1. `mysql.user` Migration

The `mysql.user` table structure is not fully compatible and cannot be migrated automatically.

- **Impact:** The administrator must create necessary users for the MariaDB database manually.
- **Workaround:** In testing, using `--skip-table=mysql.user` during dump/restore and manually creating the necessary SST user was required.
- **Reference:** MDEV-33486

2. `regexp-time-limit` Parameter

MariaDB currently does not support the `regexp-time-limit` parameter.

- **Impact:** If this variable exists in your configuration or scripts, the server may fail to start or throw errors.
- **Reference:** MySQL Sysvar: regexp_time_limit, MDEV-37403

3. `wsrep_start_position` Mismatch

MariaDB does not understand the `wsrep_start_position` format provided by MySQL due to GTID formatting differences.

- **Example:** MySQL node will use a set `wsrep_start_position` like: `"60e63a7-734c-11f0-bd90-97669e82ccf4:2284/2281/11/0747b7c5-734c-11f0-a69b-00e04ca2f8fe"`
- **Reference:** MGL-57

4. Replication Direction

Replication from MariaDB → MySQL is **not supported**.

- **Impact:** During migration, there can be **no load** directed to the MariaDB nodes until the entire cluster is migrated.

5. Testing Scope

Currently, migration from 8.0.x has been verified to work on a simple `sysbench` database workload.

MySQL to MariaDB Migrator

> **Note:**
>
> **MariaDB tool.** The MySQL to MariaDB Migrator is proprietary MariaDB software, provided free to MariaDB customers and partners under approved usage terms. It is distributed from the MariaDB community downloads page.

The **MySQL to MariaDB Migrator** is a MariaDB tool that automates end-to-end migrations from MySQL to MariaDB in a repeatable, auditable way. It orchestrates schema migration, data transfer, user and privilege migration, and post-migration validation, and it drives the standard MariaDB client tools (`mariadb-dump` , the `mariadb` client, and the `mariadb-mtk` data-transfer engine) under a single launcher.

> **Note:**
>
> The migrator is currently in **beta**. All four migration modes have been exercised end-to-end against representative source and target pairs, including AWS RDS sources and MariaDB Cloud targets. Validate it in your own environment before a production migration.

The migrator complements the manual workflows in the MySQL to MariaDB Migration: The Master Guide: the Master Guide explains the migration paths and the compatibility considerations, while the migrator automates the dump, load, user-migration, and validation steps for you.

Supported Versions

- **Source:** MySQL 8.0 and 8.4 (some modes have version-specific requirements — see Migration Modes).
- **Target:** supported MariaDB Enterprise and Community editions.
- **MariaDB Cloud** is validated as a target for the Offline Copy (`staged`), Parallel Restartable Streaming Copy (`two_step`), and Serial Streaming Copy (`one_step`) modes.
- **Platforms:** the migrator is built and tested for Linux on x86-64 and ARM64.

Migration Modes at a Glance

The launcher presents four migration modes as a numbered menu. The internal identifier in parentheses is the canonical form used in configuration files, environment variables (`MODE=...`), and the command line (`--mode <id>`).

Mode	Internal ID	Type	Best For
Serial Streaming Copy	`one_step`	Offline	Smaller databases and standard maintenance windows
Parallel Restartable Streaming Copy	`two_step`	Offline	Larger datasets that need schema-then-parallel-data loading
Offline Copy	`staged`	Offline	Source and target not network-reachable, or a deferred / two-host load
Replication	`binlog`	Online	Low-downtime cutover with ongoing replication

Each mode links to its step-by-step guide above. For the variable-level detail on all four modes in one place, see Migration Modes.

Choose a Guide

If you are not sure which mode fits, match your situation to a guide:

Your situation	Guide
A small or medium database, a standard maintenance window is acceptable, and one host can reach both the source and the target	Serial Streaming Copy
The source and target cannot reach each other (air-gapped or separate networks), or you want a checkpoint between the dump and the load	Offline Copy
A large database where a single serial transfer is too slow, you can install the `mariadb-mtk` engine, and you can start from a clean target	Parallel Restartable Streaming Copy
Downtime must be minimal, the source uses `binlog_format=ROW` with no JSON columns, and you can perform a cutover	Replication

If more than one row fits, use this order: minimal downtime points to Replication (when the source qualifies); otherwise, if one host cannot reach both sides, use Offline Copy; otherwise choose Serial Streaming Copy for a small or medium database and Parallel Restartable Streaming Copy for a large one.

How the Tool Runs

When launched interactively, the migrator first offers two top-level choices:

- **Assess & Plan** — inspect the source and target, validate connectivity and compatibility, and produce an assessment report and a migration plan. No data is moved and nothing is written to the target.
- **Assess + Run** — assess the source, then proceed to the full migration, with confirmation steps between phases.

Preview a migration with **Assess & Plan** before committing to it; the assess and plan phases write their artifacts under `artifacts/` and leave the target untouched.

In This Section

Start with the reference pages to understand how the tool installs, runs, and handles users:

See Installation and First Run.

See Migration Modes.

See Application User Migration.

See Environment Variables.

Then follow the step-by-step guide for your mode:

See Migrate with Serial Streaming Copy.

See Migrate with Offline Copy.

See Migrate with Parallel Restartable Streaming Copy.

See Migrate with Replication.

Installation and First Run

> **Note:**
>
> **MariaDB tool.** The MySQL to MariaDB Migrator is proprietary MariaDB software, provided free to MariaDB customers and partners under approved usage terms.

The MySQL to MariaDB Migrator is distributed as a release archive (`.tar.gz` or `.zip`) from the MariaDB community downloads page. Download the latest version (for example, `v1.3.1-beta`), extract it, and run the launcher — it bootstraps its own Python environment, so there is no manual setup beyond the prerequisites below.

```
tar -xzf mariadb-migrator-<version>.tar.gz
cd Mysql-to-MariaDB-Migration-<version>
./mariadb-migrator
```

The `.zip` archive is equivalent: `unzip` it, then change into the extracted directory and run `./mariadb-migrator`. The version embedded in the archive and directory names matches the release you download.

The data-transfer engine `mariadb-mtk` used by Parallel Restartable Streaming Copy is available from the same MariaDB community downloads page. See Prerequisites below.

Prerequisites

Required

- **MariaDB must be installed and running on the target host before you run the tool.** The migrator verifies the target version during preflight, but it does not install MariaDB.
- **Python 3.9 or later** on the host that runs the migrator. On the first run, the launcher creates a project-local virtual environment (`.venv`) and installs its Python dependencies into it automatically — no manual `pip install` is needed. On Debian and Ubuntu, install the venv module first: `sudo apt-get install -y python3-venv` .
- **The `mariadb` client** on the host that runs the migrator, used for connectivity, version, and database checks. If it is missing, the launcher detects your platform and offers to install it on the first run. You can also install it manually, for example with `dnf install mariadb` , `apt-get install mariadb-client` , `zypper install mariadb-client` , or `brew install mariadb` .
- **Network connectivity** from the host that runs the migrator to both the source MySQL server and the target MariaDB server. The exception is Offline Copy (`staged`) in its `dump_only` or `load_only` phase, which only needs connectivity to one side.
- For **Parallel Restartable Streaming Copy** (`two_step`), the `mariadb-mtk` engine must be installed by extracting its release archive:

  ```
  tar -xzf mariadb-mtk-<version>_<x86_64/arm_64>_linux.tar.gz
  ```

  It is available from the MariaDB community downloads page. Set the `SQLINESDATA_BIN` environment variable to the full path of the `mariadb-mtk` binary.

> **Note:**
>
> `pv` is recommended for live progress visibility but is optional. When it is missing, Offline Copy (`staged`) falls back to a 60-second file-size probe and Serial Streaming Copy (`one_step`) falls back to a 60-second heartbeat.

User Privileges

The tool expects valid privileges to already exist for the source and target admin users you provide (`SRC_ADMIN_USER` and `TGT_ADMIN_USER`). Each must be able to:

- Connect from the host that runs the migrator.
- Check, create, and drop target database objects as required by the workflow.
- Run dump and restore operations, and configure replication where applicable.

In practice this means admin-level privileges, including the ability to grant.

First Run

On the first run, the launcher:

1. Creates a project-local virtual environment at `./.venv` (unless one is already active) and installs the Python dependencies into it. Your system Python is never modified.
2. Detects the `mariadb` client and, if it is missing, shows the correct install command for your platform and offers to run it. The optional `pv` tool is offered the same way, without blocking the run.
3. Presents the interactive menu.

Later runs reuse `./.venv` and go straight to the menu.

Unattended and CI Hosts

The first-run prompts can be controlled with environment variables for unattended or CI hosts:

Variable	Effect
`MIGRATOR_ASSUME_YES=1`	Accept install prompts automatically.
`MIGRATOR_NO_SYSTEM_INSTALL=1`	Never run system installs; print the commands only.
`MIGRATOR_NO_AUTO_VENV=1`	Do not auto-create `.venv`; print the manual venv steps and exit.

Next Steps

- Migration Modes — choose and run a migration mode.
- Environment Variables — the variables required to run each mode.

This page is licensed: CC BY-SA / Gnu FDL

Migration Modes

> **Note:**
>
> **MariaDB tool.** The MySQL to MariaDB Migrator is proprietary MariaDB software, provided free to MariaDB customers and partners under approved usage terms.

The MySQL to MariaDB Migrator offers four migration modes. This page describes how to select a mode and the playbook for each one. For the variables each mode requires, see Environment Variables.

Selecting a Mode

Run the launcher interactively:

```
./mariadb-migrator
```

It first offers two top-level choices:

- **Assess & Plan** — inspect the source and target, validate connectivity and compatibility, and produce an assessment report and a migration plan. No data is moved.
- **Assess + Run** — assess the source, then proceed to the full migration (plan and run), with confirmation steps between phases.

It then presents the four modes as a numbered menu:

```
Select a migration mode:

  1) Serial Streaming Copy (mariadb-dump)            [OFFLINE]
  2) Parallel Restartable Streaming Copy (sqldata)   [OFFLINE]
  3) Offline Copy (mariadb-dump)                     [OFFLINE]
  4) Replication (binlog)                            [ONLINE]
```

The assess, plan, and run phases are also reachable non-interactively with the `--assess`, `--plan`, and `--run` flags; run `./mariadb-migrator --help` for the full list. Command-line flags bypass the menu.

> **Note:**
>
> The internal mode identifiers — `one_step`, `two_step`, `staged`, and `binlog` — are the canonical form used in the configuration file, the `MODE` environment variable, and the `--mode <id>` command-line option.

Serial Streaming Copy (`one_step`)

Best for smaller databases and standard maintenance windows. For a step-by-step walkthrough, see Migrate with Serial Streaming Copy.

- Uses `mariadb-dump` on the source and streams directly to the target `mariadb` client.
- A single pipe transfers tables sequentially, giving a predictable memory and network profile with no concurrency tuning.
- Supports a single database (`SRC_DB`) or multiple databases (`SRC_DBS="db1,db2"`).
- Strips `DEFINER` clauses by default to avoid permission errors on the target.
- Shows live progress through `pv` when available, and falls back to a 60-second heartbeat otherwise.

Parallel Restartable Streaming Copy (`two_step`)

Best for larger datasets or tighter migration windows. This mode requires the `mariadb-mtk` engine (see Installation and First Run). For a step-by-step walkthrough, see Migrate with Parallel Restartable Streaming Copy.

The mode runs in stages: a schema-only dump first, then a parallel data load through `mariadb-mtk`, a post-load row-count validation, and finally an object-finalization step for triggers, routines, and events. `mariadb-mtk` uses multiple concurrent worker sessions per database for the data phase.

Restart Behavior

Restartable, chunked loading is native to `mariadb-mtk` and on by default. Large tables (by default those with 1,000,000 or more rows) are loaded as parallel chunks, and transient errors are retried automatically within a run. Chunking requires an `AUTO_INCREMENT` column; tables without one transfer as a single stream.

`mariadb-mtk` does not resume a load across separate invocations. An interrupted or failed `two_step` run is restarted by dropping the target database or databases and re-running from a clean target. The launcher always starts a fresh run for this mode and reports a leftover target database as a conflict to drop.

Disabling Constraint Checks During the Data Load

If you hit foreign key or unique-constraint ordering errors during the parallel data load, run the following on the **target** MariaDB before starting the load:

```
SET GLOBAL FOREIGN_KEY_CHECKS=0;
SET GLOBAL UNIQUE_CHECKS=0;
```

After the object-finalization step completes, re-enable both:

```
SET GLOBAL FOREIGN_KEY_CHECKS=1;
SET GLOBAL UNIQUE_CHECKS=1;
```

This is a manual DBA step performed with an account that can set global variables — the migrator does not toggle these globals automatically.

Row-Count Validation

After the parallel data load completes successfully, the migrator validates row counts between the source and the target for each migrated database, using `mariadb-mtk`'s own validation command.

This is a post-load **report, not a gate**. The data transfer itself is the gate: a failed load stops the run before validation is reached, so reaching validation means every database transferred successfully. A row-count mismatch is recorded and surfaced, but does not fail the migration. Each database's per-table comparison and summary are written to both the per-database load log and the run log, and a concise verdict per database is echoed to the console. Set `MIGRATOR_SKIP_ROWCOUNT_VALIDATE=1` to skip the validation entirely.

Offline Copy (`staged`)

Best when the source and target are not directly network-reachable, or when you want a checkpoint between the dump and the load. For a step-by-step walkthrough, see Migrate with Offline Copy.

This mode is phase-driven through the `STAGED_PHASE` variable:

- `dump_and_load` (default) — full end-to-end migration from source to target.
- `dump_only` — dump from the source to a directory of files, then exit; the target is untouched.
- `load_only` — load existing dumps into the target; no source connection is needed, and the database list comes from the dump manifest.

Other characteristics:

- Per-database compressed dumps (`<db>.sql.gz`) are written under the run directory by default, or to a custom location set with `STAGED_DUMP_DIR` .
- A manifest tracks each database's SHA-256 hash, byte size, and approximate row count. By default each dump file's integrity is verified against this hash before it is loaded.
- Per-database dump parallelism is configurable (`STAGED_PARALLEL` , default `4`); loads run sequentially by default.
- A post-load finalize step compares the manifest against the target's `information_schema.tables` . It hard-fails on missing or empty databases and warns on row-count variance above a configurable threshold (`STAGED_FINALIZE_VARIANCE_PCT` , default 50%). Both source and target counts are InnoDB sampled estimates, so small variance is expected and does not indicate data loss.

Dump Now, Load Later on Another Host

```
# On the source host:
STAGED_PHASE=dump_only STAGED_DUMP_DIR=/mnt/transfer/dumps ./mariadb-migrator

# Transfer the directory:
scp -r /mnt/transfer/dumps target-host:/mnt/load/

# On the target host:
STAGED_PHASE=load_only STAGED_DUMP_DIR=/mnt/load/dumps ./mariadb-migrator
```

> **Warning:**
>
> Offline Copy does not capture writes made to the source during the dump. If downtime is unacceptable, use Replication (`binlog`) instead.

> **Warning:**
>
> Target connections negotiate TLS where the server requires it (for example, MariaDB Cloud), but server-certificate verification on the target side is not yet configurable: connections are encrypted in transit but not authenticated against a trusted CA. Source-side TLS verification works as expected through `SRC_SSL_MODE` .

Replication (`binlog`)

Best for low-downtime cutover. For a step-by-step walkthrough, see Migrate with Replication.

- Seeds the target from a consistent dump snapshot with embedded binlog coordinates, then starts MariaDB replication from the MySQL binary log using the `REPL_USER` and `REPL_PASS` credentials.
- Verifies replication thread health and lag after replication starts.
- For MySQL 8.4 sources, an upstream `mysqldump` 8.4 or later must be available, because 8.4 servers reject `SHOW MASTER STATUS` . The migrator detects this and fails fast at preflight.

> **Warning:**
>
> **Replication requires `binlog_format=ROW` on the source and does not support schemas that contain JSON columns.** Both conditions are checked upfront — at the launcher, the assessment, and preflight — and an operator with either configuration is blocked and routed to one of the offline modes, which are unaffected by these limitations. To use Replication, set `binlog_format = ROW` under `[mysqld]` in the source `my.cnf` and restart the source MySQL server.

Post-Load Optimizer Statistics

After a dump-and-restore, the target's optimizer statistics are empty or stale, which can lead to poor query plans until they are refreshed. The migrator can run `ANALYZE TABLE` across the migrated databases on the target as a final step, so the optimizer has accurate statistics immediately.

A prompt — `Run ANALYZE TABLE on target after load? (y/n)` — appears during setup, just after the application-user prompt. It defaults to `y` and is shown only for the modes where a fresh load occurs: Serial Streaming Copy (`one_step`), Parallel Restartable Streaming Copy (`two_step`), and Offline Copy (`staged`). It is not part of Replication (`binlog`), where replication keeps changing the tables after the seed.

- Set `ANALYZE_TARGET=0` (or answer `n`) to skip it.
- The step is skipped automatically when Offline Copy runs as `dump_only` , because no load happens on that host.
- A connection failure to the target stops the run; an `ANALYZE TABLE` error on an individual table is reported but does not fail the migration.
- A report listing the tables analyzed, status counts, and any per-table errors is written to the run's artifacts directory.

Notes and Limitations

- The migration fails by default if the target database already exists. Set `ALLOW_TARGET_DB_OVERWRITE=1` only when an overwrite is intentional. (For `staged` `load_only` , the database list comes from the manifest, and the same overwrite check applies before the load begins.)
- `root` source and target users are blocked by default; set `ALLOW_ROOT_USERS=1` to allow them.
- Offline Copy per-database load resume is not supported. If a multi-database load fails partway through, drop the partially loaded databases on the target and re-run with `STAGED_PHASE=load_only` .
- The migrator is built and tested for Linux on x86-64 and ARM64. Validate it in your target environment before production use.

Application User Migration

> **Note:**
>
> **MariaDB tool.** The MySQL to MariaDB Migrator is proprietary MariaDB software, provided free to MariaDB customers and partners under approved usage terms.

When you answer `y` to the `Migrate application users? (y/n)` prompt, the migrator migrates application users and roles from the source MySQL server to the target MariaDB server during the run phase. This runs in every mode (`one_step` , `two_step` , `staged` , and `binlog`), and the assess phase produces a prediction report ahead of the run.

What Happens to Each User

User creation on the target is plugin-aware: the source authentication plugin determines how each user is migrated.

Source Plugin	Outcome on Target
`mysql_native_password` (with hash)	Migrated with the original password preserved. The hash is ported using MariaDB's `IDENTIFIED VIA ... USING` syntax.
`mysql_native_password` (no hash)	Created with the default password supplied at the prompt, with `PASSWORD EXPIRE` set so the user must change it on first login.
`caching_sha2_password`, `sha256_password`	Created with the default password and `PASSWORD EXPIRE`. These hash formats are not portable across the engine boundary.
`auth_socket`, `unix_socket`, `auth_pam`, `mysql_no_login`, anything else	**Skipped** — not created on the target. Configure these manually after the migration if needed.

Roles are detected separately and replayed on the target with `CREATE ROLE IF NOT EXISTS`. They are not migrated as users.

Grants

After each user is created, the migrator runs `SHOW GRANTS` against the source and replays each grant on the target. Grants that fail at replay time are dropped from the migration and listed in the per-user report. Common causes are:

- MySQL 8.0 / 8.4 dynamic privileges that MariaDB does not recognize, such as `APPLICATION_PASSWORD_ADMIN`, `SYSTEM_USER`, or `SET_ANY_DEFINER`.
- A grant on a database that does not exist on the target.
- A grant to a role that was not migrated (because the source user was identified as a role and skipped from the user loop).
- The target admin user lacking `GRANT OPTION` on the database being granted on.

Default Password Handling

The default password supplied at the `Default password for app users:` prompt is used for every user that cannot have its original password preserved — that is, all non-native-password users and native-password users without a hash. Every such user is also marked `PASSWORD EXPIRE`, so they must change their password on first login.

> **Warning:**
>
> The default password is recorded in plain text in the user-migration report. Treat that file as sensitive, and rotate the default password after the migration completes.

Reports

Two artifacts are produced when user migration is enabled:

- **`user_assessment_report.txt`**, written by the assess phase, predicts which users would be preserved, defaulted, or skipped. No writes to the target are performed.
- **`user_migration_report.txt`**, written by the run phase, records what actually happened: roles created, users preserved, users whose password was reset to the default, users skipped, users that failed to migrate, and the full list of grants that were dropped.

The two reports use a parallel structure, so an `Assess + Run` migration can diff them afterward to confirm the prediction matched the outcome.

Limitations and Known Behavior

- Replication, monitoring, and backup-tool accounts (for example `repl_user`, `pmm_*`, or `xtrabackup`) are migrated as application users in this release. Clean them up manually on the target after the migration.

- MySQL 8.4 sources default to `caching_sha2_password` and ship with `mysql_native_password` disabled, so most or all users on a fresh 8.4 source land on the default-password path. Plan a password-rotation pass before re-enabling application traffic on the target.
- The dump phase may replay user-related rows from `mysql.user` as part of the data load, which can produce duplicate or conflicting entries alongside what the user-migration step created. If the user set looks off, review `SELECT user, host, plugin, is_role FROM mysql.user` on the target after the migration.

Environment Variables

> **Note:**
>
> **MariaDB tool.** The MySQL to MariaDB Migrator is proprietary MariaDB software, provided free to MariaDB customers and partners under approved usage terms.

The migrator reads its configuration from environment variables (or the configuration file it writes from your interactive answers). This page lists the variables **required** to run each mode. A complete reference of every variable, with defaults and descriptions, ships with the tool.

> **Note:**
>
> The interactive launcher prompts for any required input that is not already set, so you do not have to export these variables by hand. Set them explicitly for scripted or unattended runs.

Common Variables

Most modes share the same source and target connection variables:

Variable	Purpose
`SRC_HOST`, `SRC_PORT`	Source MySQL host and port.
`SRC_ADMIN_USER`, `SRC_ADMIN_PASS`	Source admin credentials.
`SRC_DB` or `SRC_DBS`	A single source database, or a comma-separated list.
`TGT_HOST`, `TGT_PORT`	Target MariaDB host and port.
`TGT_ADMIN_USER`, `TGT_ADMIN_PASS`	Target admin credentials.
`SRC_SSL_MODE`	Optional source TLS mode (`DISABLED`, `PREFERRED`, `REQUIRED`, `VERIFY_CA`, or `VERIFY_IDENTITY`) for TLS-required sources.

Serial Streaming Copy (`one_step`)

Requires the common source and target variables above. Optional:

- `ANALYZE_TARGET` — `1` by default; runs `ANALYZE TABLE` on the target after the load to refresh optimizer statistics. Set to `0` to skip. (Applies to `one_step`, `two_step`, and `staged`.)

Parallel Restartable Streaming Copy (`two_step`)

Requires the common source and target variables. Optional:

- `SQLINESDATA_BIN` — full path to the `mariadb-mtk` binary; auto-detected from a `sqldata` or `sqlinesdata` binary on `PATH`.
- `MIGRATOR_SKIP_ROWCOUNT_VALIDATE` — set to `1` to skip the post-load row-count validation.

Replication (`binlog`)

Requires the common source and target variables, plus:

- `REPL_USER` , `REPL_PASS` — replication credentials.

Optional:

- `SRC_BINLOG_FILE` , `SRC_BINLOG_POS` — binlog coordinates; auto-captured during the seed if not set.
- `BINLOG_COORD_FILE` — where captured coordinates are written (default: `artifacts/binlog_coords.env`).
- `BINLOG_MAX_LAG_SECS` — replication lag threshold in seconds (default: `30`).

Offline Copy (`staged`)

The phase selector and connection requirements depend on the phase:

- `STAGED_PHASE` — `dump_and_load` (default), `dump_only` , or `load_only` .
- Source variables are required for `dump_and_load` and `dump_only` .
- Target variables are required for `dump_and_load` and `load_only` .

Dump and load tuning (all optional):

Variable	Default	Purpose
`STAGED_DUMP_DIR`	run directory	Dump location; required for `load_only` to point at the manifest directory.
`STAGED_COMPRESS`	`1`	Gzip-compress the dump.
`STAGED_PV`	`1`	Show a progress meter through `pv` or the fallback probe.
`STAGED_PARALLEL`	`4`	Concurrent per-database dumps.
`STAGED_LOAD_PARALLEL`	`1`	Concurrent per-database loads.
`STAGED_VERIFY_CHECKSUM`	`1`	Verify each dump file's integrity before load.
`STAGED_DISK_HEADROOM_FACTOR`	`2`	Multiplier on the source data size for the free-space check.
`STAGED_FINALIZE_VARIANCE_PCT`	`50`	Row-count variance threshold above which finalize warns.
`STAGED_CONFIRM_OFFLINE`	—	Set to bypass the interactive offline-acknowledgment prompt for non-interactive runs.

Run-Control Variables

These apply across modes:

Variable	Purpose
`MODE`	Selects the mode (`one_step` , `two_step` , `staged` , or `binlog`) for non-interactive runs.
`ALLOW_TARGET_DB_OVERWRITE`	Set to `1` to allow migrating into an existing target database.
`ALLOW_ROOT_USERS`	Set to `1` to allow `root` as a source or target admin user.
`FORCE_NEW_RUN`	Set to `1` to force a fresh run instead of resuming a previous one.

Migrate with Serial Streaming Copy

This guide walks through a complete MySQL to MariaDB migration in **Serial Streaming Copy** (`one_step`) mode. You preview the migration with Assess & Plan, run it, and verify the result on the target.

Serial Streaming Copy is the most direct mode: it pipes `mariadb-dump` from the source straight into the `mariadb` client on the target, one table at a time. It needs no extra data-transfer engine and no replication setup, which

makes it the right choice for a first migration and for smaller databases that can move within a standard maintenance window.

> **Note:**
>
> The migrator is in **beta**. Run this procedure against a non-production target first, and validate the result before you migrate a production database.

This guide uses the `sakila` sample database as the example. Substitute your own database name wherever `sakila` appears.

> **Note:**
>
> **Following along with the sample?** `sakila` is MySQL's official sample database. To set it up on your source server, download the archive from the MySQL example databases page, extract it, and load the two files:
>
> ```
> mysql -u root -p < sakila-schema.sql   # tables, views, routines, triggers
> mysql -u root -p < sakila-data.sql     # data
> ```
>
> See the Sakila documentation for the full schema. If you are migrating your own database instead, skip this step.

Before You Begin

You need a source **MySQL 8.0 or 8.4** server with the database you want to migrate, and a target **MariaDB** server that is already installed and running. The migrator checks the target version but does not install MariaDB. The host running the migrator needs network connectivity to both servers.

You also need **admin credentials** on both servers that can connect from the migrator host, create and drop databases, and run dump and restore operations. Avoid `root`; the migrator blocks `root` by default.

Finally, the migrator host needs **Python 3.9 or later** and the **`mariadb` client**. The launcher bootstraps its own Python environment and offers to install the client if it is missing. On Debian or Ubuntu, install the venv module first with `sudo apt-get install -y python3-venv`. The optional `pv` tool improves progress visibility during the transfer but is not required.

Step 1: Download and Start the Migrator

See Installation and First Run for details on downloading and installing the MariaDB Migrator.

On the first run, the launcher creates a project-local Python environment (`.venv`), installs its dependencies into it, and checks for the `mariadb` client. Your system Python is never modified, and later runs reuse `.venv` and go straight to the menu.

```
--------------------------------------------------------------------
 Welcome to the MySQL to MariaDB Migration Tool
 Tool Version: 1.3.1-beta (Build 20260622)
 Supported Sources: MySQL 8.0, 8.4
--------------------------------------------------------------------
==> Validating execution environment...
==> No active virtualenv detected. Creating one at ./.venv ...
Installing missing dependencies: typer click rich PyYAML
Successfully installed PyYAML-6.0.2 click-8.1.7 rich-13.7.1 typer-0.12.3 ...
==> Environment ready.
==> Checking system dependencies...
==> Database client found: /usr/bin/mariadb
==> pv found (dump progress will be shown).
==> System dependencies ready.

What would you like to do?
  1) Assess & Plan    Inspect source and target, validate connectivity and
                      compatibility, and produce an assessment report and the
                      migration plan. No data is moved.
  2) Assess + Run     Assess the source, then proceed to the full migration
                      (plan + run, with confirm steps between phases).
  q) Quit
```

Step 2: Preview with Assess & Plan

Choose **1) Assess & Plan** for the preview. This phase never writes to the target. The migrator prompts for the connection details it needs:

Prompt	Example value
Source host / port	`mysql.example.com` / `3306`
Source admin user / password	`migadmin` / (entered at the prompt)
Source database	`sakila`
Target host / port	`mariadb.example.com` / `3306`
Target admin user / password	`migadmin` / (entered at the prompt)

Then select mode **1) Serial Streaming Copy (mariadb-dump) [OFFLINE]**. The assess phase checks connectivity and source-to-target compatibility, inventories the schema, and writes its reports under `artifacts/assess_<timestamp>/`.

```
== Precheck runner ==
Host: mysql.example.com  Port: 3306  User: migadmin
---- mysql_version ----
8.0.46
---- json_columns ----
(no rows)
---- engines_summary ----
InnoDB  59
Precheck complete.
==> Assess application users on source
Roles found on source                : 0
Users with portable native password  : 0
Users requiring default password     : 0
Users that would be SKIPPED          : 0
ASSESSMENT: PASS (see artifacts/report.json and run.log)
```

Review the reports before you run the migration. The **assessment report** confirms connectivity and compatibility. The **`user_assessment_report.txt`** predicts which application users would be migrated with their password preserved, which would be reset to a default password, and which would be skipped. In this example the `sakila` source has no application accounts of its own, so the user counts are zero; on a real database this report lists exactly which users fall into each category. For how the migrator classifies users, see Application User Migration.

Step 3: Run the Migration

Start the launcher again and choose **2) Assess + Run**, then select **1) Serial Streaming Copy** again. The migrator re-runs the assessment, then prompts for a few decisions before it moves any data.

The **`Migrate application users? (y/n)`** prompt controls whether application users and roles are migrated along with the data. If you answer `y`, the migrator also asks for a **`Default password for app users:`** used for any user whose original password cannot be carried over. The **`Run ANALYZE TABLE on target after load? (y/n)`** prompt defaults to `y`; it refreshes the target's optimizer statistics after the load so queries get good plans immediately.

The migrator then streams the data. Because Serial Streaming Copy is a logical dump and restore, it carries the full schema across: tables, views, stored procedures, functions, triggers, and events. It strips `DEFINER` clauses by default so those objects restore without permission errors on the target.

Output is captured to a run log rather than streamed to your terminal, and each phase prints a `tail -f` hint. To watch live progress, open a second shell and run `tail -f artifacts/run_one_step_<timestamp>/run.log`.

```
==> One-step migration (mariadb-dump | mariadb)
Source MySQL: 8.0.46  Dump tool: mariadb-dump
Source: mysql.example.com:3306  DB: sakila
Target: mariadb.example.com:3306
0:00:00 [ <=>                                                                ]
One-step migration completed.
==> Post-load ANALYZE TABLE on target (refresh optimizer statistics)
    [done] sakila: 16 table(s) in 0s
RUN: PASS
```

The `pv` line is the live transfer heartbeat. For `sakila` the transfer finishes in under a second, so you see a single heartbeat; on a larger database `pv` prints a progress line every 10 seconds, and a 60-second heartbeat is used only when `pv` is not installed.

> **Note:**
>
> By default the migration stops if the target database already exists, so an accidental overwrite cannot happen. To migrate into an existing database, set `ALLOW_TARGET_DB_OVERWRITE=1` before the run.

Step 4: Verify the Result

When the run finishes, confirm the migration on the target. The run artifacts under `artifacts/run_one_step_<timestamp>/` include **`user_migration_report.txt`** (what happened to each user) and **`analyze_target_report.txt`** (the tables analyzed and any per-table errors).

```
# user_migration_report.txt
Roles created on target              : 0
Users migrated with original password: 0
Users migrated with default password : 0  <- PASSWORD EXPIRE set
Grants dropped (incompatible)        : 0

# analyze_target_report.txt
Databases analyzed   : 1  (sakila)
Tables analyzed      : 16
  status OK          : 16
Overall              : PASS
```

Then spot-check the data on the target and compare against the source:

```
mariadb -h mariadb.example.com -u migadmin -p \
  -e "SELECT COUNT(*) FROM sakila.film; SHOW TABLES FROM sakila;"
```

```
+----------+
| COUNT(*) |
+----------+
|     1000 |
+----------+
actor
address
category
... (16 base tables and 7 views)
```

Object fidelity is the important check for Serial Streaming Copy. On the migrated target, `sakila` has **16 base tables, 7 views, 6 stored routines, and 6 triggers**, matching the source, and the stored functions and procedures execute and return the same results as the source. Confirm the stored objects with:

```
mariadb -h mariadb.example.com -u migadmin -p -N -e "
  SELECT COUNT(*) FROM information_schema.routines WHERE routine_schema='sakila';
  SELECT COUNT(*) FROM information_schema.triggers WHERE trigger_schema='sakila';"
```

After the Migration

Rotate any default passwords. A user that could not keep its original password was created with the default password you supplied and marked `PASSWORD EXPIRE`. That default is recorded in plain text in `user_migration_report.txt`, so treat the file as sensitive and rotate the password before re-enabling application traffic. This is common when migrating from MySQL 8.4, which defaults to `caching_sha2_password`.

Clean up infrastructure accounts. Replication, monitoring, and backup accounts are migrated as application users in this release; remove any that do not belong on the target. Once you have verified the data and credentials, repoint your application at the target MariaDB server.

Run Without Prompts

For a scripted, non-interactive run, set the connection details as environment variables and the launcher skips the prompts:

```
MODE=one_step \
SRC_HOST=mysql.example.com SRC_PORT=3306 SRC_ADMIN_USER=migadmin SRC_ADMIN_PASS=... SRC_DB=sakila \
TGT_HOST=mariadb.example.com TGT_PORT=3306 TGT_ADMIN_USER=migadmin TGT_ADMIN_PASS=... \
./mariadb-migrator --run
```

See Environment Variables for the full list.

Other Modes

If Serial Streaming Copy does not fit your situation, see the migrator overview to choose another mode: Offline Copy for hosts that cannot reach each other, Parallel Restartable Streaming Copy for large databases, or Replication for a low-downtime cutover.

This page is licensed: CC BY-SA / Gnu FDL

Migrate with Offline Copy

This guide walks through a complete MySQL to MariaDB migration in **Offline Copy** (`staged`) mode. You dump the source database to compressed files with a manifest, move that directory to where the target lives, and load it there.

Offline Copy is the right mode when the source and target cannot reach each other directly, for example across an air gap or between separate networks, or when you simply want a verifiable checkpoint between the dump and the load. It uses the same `mariadb-dump` and `mariadb` tooling as Serial Streaming Copy, but writes to disk in between instead of streaming through a single pipe.

> **Note:**
>
> The migrator is in **beta**. Run this procedure against a non-production target first, and validate the result before you migrate a production database.

This guide uses the `sakila` sample database as the example. Substitute your own database name wherever `sakila` appears.

> **Note:**
>
> **Following along with the sample?** `sakila` is MySQL's official sample database. Download it from the MySQL example databases page, extract it, and load `sakila-schema.sql` then `sakila-data.sql` into your source server.

Before You Begin

You need a source **MySQL 8.0 or 8.4** server and a target **MariaDB** server already installed and running. Unlike the online modes, Offline Copy does not need a single host that can reach both: the dump phase needs only the source, and the load phase needs only the target. You do need a directory you can move between the two sides, with free space for the compressed dump.

You also need **admin credentials** on each server that can connect from the host running that phase and can dump or restore databases. Avoid `root`; the migrator blocks it by default.

The host that runs each phase needs **Python 3.9 or later** and the **`mariadb` client**. The launcher bootstraps its own Python environment and offers to install the client if it is missing. The optional `pv` tool improves progress visibility.

Step 1: Download and Start the Migrator

See Installation and First Run for details on downloading and installing the MariaDB Migrator.

Step 2: Understand the Phases

Offline Copy is driven by the `STAGED_PHASE` setting, which selects which part of the migration runs:

- `dump_and_load` (default) runs the whole migration on a single host that can reach both the source and the target.
- `dump_only` dumps from the source to a directory of files and then exits. The target is untouched, and only source connectivity is needed.
- `load_only` loads existing dump files into the target. Only target connectivity is needed, and the database list comes from the manifest in the dump directory.

The two-host workflow below uses `dump_only` and `load_only`. If one host can reach both servers, you can run `dump_and_load` instead and skip the transfer step.

Step 3: Dump on the Source

On the host that can reach the source, run the dump phase, pointing `STAGED_DUMP_DIR` at a directory you can move. `STAGED_CONFIRM_OFFLINE=1` acknowledges without an interactive prompt that writes to the source during the dump are not captured.

```
STAGED_PHASE=dump_only STAGED_DUMP_DIR=/mnt/transfer/dumps \
  STAGED_CONFIRM_OFFLINE=1 ./mariadb-migrator
```

The dump phase reports each database as it finishes and prints a summary:

```
==> Staged dump (mariadb-dump | pv | gzip > file, per database)
Source MySQL : 8.0.46
Dump tool    : mariadb-dump
Compress     : gzip
Databases    : sakila

==> Dumping: sakila
   sakila: 0:00:00 [================>          ]  51%
    [done] sakila: 702KB, 47685 approx rows, 0s

==> Staged dump complete.
    Databases : 1
    Total size: 702KB
    Manifest  : /mnt/transfer/dumps/manifest.txt
```

The directory now holds one compressed file per database (`sakila.sql.gz`) and a `manifest.txt` that records each database's SHA-256, byte size, and approximate row count:

```
# staged-migration-manifest v1
# source_host: mysql.example.com
# source_version: 8.0.46
# dump_tool: mariadb-dump
# database  filename    sha256  size_bytes  approx_rows
sakila  sakila.sql.gz   c1040adb994b9a6c85a1c777b2abba7ea19d5dd9f86cc53e5f3b09b971fc8720    718005  47685
```

Step 4: Transfer the Dump

Move the dump directory to the target side by whatever transport your environment allows: `scp` , a shared volume, removable media, or an object-store bucket. The manifest travels with the dump files and is used to verify them at load time.

```
scp -r /mnt/transfer/dumps target-host:/mnt/load/
```

Step 5: Load on the Target

On the host that can reach the target, run the load phase against the transferred directory:

```
STAGED_PHASE=load_only STAGED_DUMP_DIR=/mnt/load/dumps \
  STAGED_CONFIRM_OFFLINE=1 ./mariadb-migrator
```

The load phase reads the manifest, verifies each file's SHA-256 before loading it, loads each database, refreshes optimizer statistics with `ANALYZE TABLE` , and finalizes:

```
==> Preflight checks (staged)
Phase: load_only
Manifest: 1 database(s) — sakila

==> Loading: sakila (file: sakila.sql.gz)
    checksum: OK
    [done] sakila: loaded 702KB in 2s

==> Staged load complete.
```

Step 6: Verify the Result

After the load, a finalize step compares the manifest against the target's `information_schema.tables` . It hard-fails on a missing or empty database and warns on row-count variance above the threshold:

```
==> Staged finalize (post-load sanity counts and manifest verification)
Per-DB verification:
  Database                 Exists    Tables  Source rows     Target rows     Variance
  ------------------------ --------- ------- --------------- --------------- --------
  sakila                   OK        16      ~47685          ~47375          -0.7%

==> Staged finalize complete.
    Databases verified: 1
```

The -0.7% variance is expected. Both row counts are InnoDB sampled estimates from `information_schema`, not exact `COUNT(*)` results, so small differences are normal and do not indicate data loss. The checksum verified during load is the authoritative file-integrity check. For an exact check, run `SELECT COUNT(*)` on a few tables on both servers.

After the Migration

Review the run reports under `artifacts/run_staged_<timestamp>/`, rotate any default passwords recorded in the user migration report, and remove replication, monitoring, or backup accounts that do not belong on the target. Repoint your application at the target MariaDB server once you have verified the data and credentials.

Known Limitations

> **Warning:**
>
> Offline Copy does not capture writes made to the source during the dump. For a consistent cutover, stop application traffic to the source before the dump and resume it on the target only after the load completes. If downtime is unacceptable, use Replication instead.

> **Warning:**
>
> Target-side TLS certificate verification is not yet configurable. Connections to TLS-required targets, such as MariaDB Cloud, are encrypted but not verified against a trusted CA. Source-side TLS works as expected through `SRC_SSL_MODE`.

Per-database load resume is not supported. If a multi-database load fails partway, drop the partially loaded databases on the target and re-run with `STAGED_PHASE=load_only`.

Reference

The dump phase accepts tuning variables including `STAGED_PARALLEL` (concurrent per-database dumps, default 4), `STAGED_COMPRESS` (gzip on by default), and `STAGED_FINALIZE_VARIANCE_PCT` (the warning threshold, default 50). See Environment Variables for the full list.

Other Modes

If Offline Copy does not fit your situation, see the migrator overview to choose another mode: Serial Streaming Copy for a single-pipe transfer when both servers are reachable, Parallel Restartable Streaming Copy for large databases, or Replication for a low-downtime cutover.

This page is licensed: CC BY-SA / Gnu FDL

Migrate with Parallel Restartable Streaming Copy

This guide walks through a complete MySQL to MariaDB migration in **Parallel Restartable Streaming Copy** (`two_step`) mode. The migrator dumps the schema first, loads the data in parallel through the `mariadb-mtk` engine, validates row counts, and finalizes the remaining objects.

This mode is for larger databases where a single serial transfer is too slow. It dumps the schema, then loads table data through multiple concurrent worker sessions, then applies triggers, routines, and events at the end.

> **Note:**
>
> The migrator is in **beta**. Run this procedure against a non-production target first, and validate the result before you migrate a production database.

This guide uses the `employees` sample database, which is large enough (about 3.9 million rows across six tables) to show the parallel load and the row-count validation doing real work. Substitute your own database name wherever `employees` appears.

> **Note:**
>
> **Following along with the sample?** `employees` is MySQL's sample database for larger datasets, from the datacharmer/test_db project. Clone it and load it into your source with `mysql -u root -p < employees.sql` from inside the repository directory.

Before You Begin

You need a source **MySQL 8.0 or 8.4** server with the database you want to migrate, and a target **MariaDB** server already installed and running. The host running the migrator needs network connectivity to both servers.

You need **admin credentials** on both servers that can connect from the migrator host and create, drop, dump, and restore databases. Avoid `root`; the migrator blocks it by default. The migrator host needs **Python 3.9 or later** and the **`mariadb` client**.

The target must be **clean** for this mode: Parallel Restartable Streaming Copy does not resume across separate invocations, so if a target database already exists from a previous attempt, drop it before you start.

The mariadb-mtk engine

This mode requires the `mariadb-mtk` data-transfer engine. The other three modes do not use it. See the "Required" section of the Installation and First Run page for details on downloading and installing mariadb-mtk.

Step 1: Download and Start the Migrator

See Installation and First Run for details on downloading and installing the MariaDB Migrator.

Step 2: Preview with Assess & Plan

Choose **1) Assess & Plan**, supply the source and target connection details when prompted, and select mode **2) Parallel Restartable Streaming Copy (sqldata) [OFFLINE]**. This phase checks connectivity and compatibility and writes its reports under `artifacts/assess_<timestamp>/` without touching the target. Review the assessment before running.

Step 3: Run the Migration

Start the launcher again, choose **2) Assess + Run**, and select Parallel Restartable Streaming Copy. The run executes four steps in order: a schema-only dump, the parallel data load, row-count validation, and object finalization.

The schema is dumped in two parts. The pre-data DDL (tables, indexes, foreign keys) is loaded first, with triggers, routines, and events held back. Those post-data objects are applied during finalization rather than before the load, so a trigger cannot fire and re-insert rows while data is still streaming in.

Watch live progress with `tail -f artifacts/run_two_step_<timestamp>/run.log` from a second shell.

How the parallel load behaves

The engine transfers the database with several concurrent sessions (the `-ss` value, default 4), working on different tables at once. In this run of `employees`, four sessions moved all six tables and 3.9 million rows transferred in about three seconds:

```
Transferring database (4 concurrent sessions):
employees.departments  - Started (1 of 6, 1 chunk, session 1)
employees.dept_emp     - Started (2 of 6, 1 chunk, session 2)
employees.employees    - Started (4 of 6, 1 chunk, session 3)
employees.salaries     - Started (5 of 6, 1 chunk, session 4)
employees.titles       - Started (6 of 6, 1 chunk, session 1)
  Rows written:  3919015 (3.9M rows)
  Transfer time: 3.4 sec (1144238 rows/s, 134.9 MB, 39.4 MB/s)
```

That parallelism is across tables. The engine can also split a single large table into parallel chunks, but that is a separate, opt-in behavior: it is gated by `large_tables_parallel` (off in the shipped `sqldata.cfg`) and additionally requires the table to have an `AUTO_INCREMENT` column. The `employees` tables use composite primary keys with no `AUTO_INCREMENT`, so each table, `salaries` included, transfers as a single stream within its session, which is what the `1 chunk` markers show. To split one very large table across sessions, set `large_tables_parallel=yes` and ensure the table has an `AUTO_INCREMENT` column.

Row-count validation

After the load, the tool validates source and target row counts per database using the engine's own validate command. This is a report, not a gate: the data transfer is the gate, so reaching validation means every database loaded successfully. A mismatch is recorded and surfaced but does not fail the migration.

```
===== row-count validation: employees =====
  Total number of tables:         6
    With the different row count: 0
  Total number of rows:           3919015 in source, 3919015 in target
[employees] row counts OK (all tables equal)
==> Row-count validation: all selected database(s) match
```

Set `MIGRATOR_SKIP_ROWCOUNT_VALIDATE=1` to skip this step.

Step 4: Verify the Result

When the run finishes, confirm the migration on the target. In this run the target `employees` matched the source exactly: 6 base tables and 2 views, with 300024 rows in `employees` and 2844047 in `salaries`. The views are part of the schema dump and are created before the data load; only triggers, routines, and events are applied during finalize.

```
mariadb -h mariadb.example.com -u migadmin -p -t -e "
  SELECT table_type, COUNT(*) FROM information_schema.tables
   WHERE table_schema='employees' GROUP BY table_type;
  SELECT COUNT(*) AS salaries FROM employees.salaries;"
```

Restart Behavior

> **Warning:**
>
> `mariadb-mtk` does not resume a load across separate invocations. An interrupted or failed run is restarted by dropping the target database, then re-running from a clean target. The launcher always starts a fresh run for this mode and reports a leftover target database as a conflict to drop.

Chunked loading is still restartable within a run: transient errors are retried automatically (`restart_attempts`, default 10). The no-resume limitation applies only across separate invocations.

Constraint Checks During Load

By default the tool disables foreign-key checks on the target during the parallel load (`TWO_STEP_KEEP_FK_CHECKS=0`) so cross-table load order does not cause failures. If you keep them on and hit foreign-key or unique-constraint ordering errors, disable the checks on the target before the load and re-enable them after finalize. The tool does not toggle these for you in that case.

```
-- Before the load:
SET GLOBAL FOREIGN_KEY_CHECKS=0;
SET GLOBAL UNIQUE_CHECKS=0;
-- After finalize:
SET GLOBAL FOREIGN_KEY_CHECKS=1;
SET GLOBAL UNIQUE_CHECKS=1;
```

After the Migration

Review the run reports under `artifacts/run_two_step_<timestamp>/` , rotate any default passwords from the user migration report, and remove infrastructure accounts that do not belong on the target. Repoint your application at the target MariaDB server once you have verified the data and credentials.

Other Modes

If Parallel Restartable Streaming Copy does not fit your situation, see the migrator overview to choose another mode: Serial Streaming Copy for a smaller database, Offline Copy for hosts that cannot reach each other, or Replication for a low-downtime cutover.

This page is licensed: CC BY-SA / Gnu FDL

Migrate with Replication

This guide walks through a complete MySQL to MariaDB migration in **Replication** (`binlog`) mode. The migrator seeds the target from a consistent snapshot with embedded binlog coordinates, starts MariaDB replication from the MySQL binary log, and verifies it. The target then stays current with the source until you perform a short cutover.

This is the mode to use when downtime must be minimal. Unlike the offline modes, it does not finish in a single pass; it establishes ongoing replication that you cut over when you are ready.

> **Note:**
>
> The migrator is in **beta**. Run this procedure against a non-production target first, and validate the result before you migrate a production database.

This guide uses the `sakila` sample database as the example. Substitute your own database name wherever `sakila` appears.

> **Note:**
>
> **Following along with the sample?** `sakila` is MySQL's official sample database. Download it from the MySQL example databases page, extract it, and load `sakila-schema.sql` then `sakila-data.sql` into your source server.

Before You Begin

You need a source **MySQL 8.0 or 8.4** server and a target **MariaDB** server already installed and running. The host running the migrator needs network connectivity to both, and the target MariaDB must be able to reach the source MySQL directly, because the replica connects to the source to read its binary log.

You need **admin credentials** on both servers (not `root` , which is blocked by default), plus a **replication user** the migrator will use; you supply its name and password as `REPL_USER` and `REPL_PASS` , and the migrator creates it on

the source if it does not exist. The migrator host needs **Python 3.9 or later** and the `mariadb` **client**.

Source requirements

> **Warning:**
>
> Replication requires `binlog_format=ROW` on the source and does not support schemas that contain JSON columns. Both conditions are enforced at the launcher, the assessment, and preflight, so a source with either is blocked upfront and routed to an offline mode. To use Replication, set `binlog_format = ROW` under `[mysqld]` in the source `my.cnf` and restart the source MySQL server.

A **MySQL 8.4** source additionally needs an upstream `mysqldump` 8.4 or later available, because 8.4 servers reject `SHOW MASTER STATUS`. An **8.0** source uses `mariadb-dump` directly and needs no extra client, which makes 8.0 the simpler source for this mode.

Step 1: Download and Start the Migrator

See Installation and First Run for details on downloading and installing the MariaDB Migrator.

On the first run, the launcher creates a project-local Python environment (`.venv`) and checks for the `mariadb` client. Your system Python is never modified.

Step 2: Preview with Assess & Plan

Choose **1) Assess & Plan**, supply the source and target connection details and the replication user when prompted, and select mode **4) Replication (binlog) [ONLINE]**. The assessment inventories the source and checks compatibility before anything is written. For Replication the decisive check is JSON columns: `sakila` has none, so the source clears the gate (the `binlog_format=ROW` requirement is confirmed when the migration runs).

```
== Precheck runner ==
Host: mysql.example.com  Port: 3306  User: migadmin
---- mysql_version ----
8.0.46
---- json_columns ----
(no rows)
---- engines_summary ----
InnoDB  59
Precheck complete.
ASSESSMENT: PASS (see artifacts/report.json and run.log)
```

If the source has a JSON column, the assessment stops and lists the offending columns, then re-prompts for the database name(s) so you can drop or exclude the offending database and retry. If the JSON columns are ones you need to migrate, choose one of the offline modes instead.

Step 3: Run the Migration

Start the launcher again, choose **2) Assess + Run**, and select Replication. The migrator first re-checks source compatibility with a Replication-specific preflight, then runs three steps: seed, start replication, and verify. Watch progress with `tail -f artifacts/run_binlog_<timestamp>/run.log` .

```
==> Preflight checks (binlog)
Source MySQL: 8.0.46 (using: SHOW MASTER STATUS;)
Checking source schemas for JSON columns...
Checking source binary logging...
Checking source binlog format...
Checking source master/binary-log status visibility...
Preflight complete.
```

Seed the target

A consistent snapshot is taken with `mariadb-dump --single-transaction --master-data=2`, which embeds the binlog coordinates, and is restored to the target. The coordinates are saved for the next step.

```
==> Binlog migration: seed target from source snapshot
Source MySQL: 8.0.46  Dump tool: mariadb-dump
Creating source snapshot with binlog coordinates (--master-data=2)...
Restoring snapshot to target...
Seed completed.
```

```
# binlog_coords.env
SRC_BINLOG_FILE=mysql-bin.000004
SRC_BINLOG_POS=66378596
```

Start replication

The migrator ensures the replication user exists on the source (created `WITH mysql_native_password`, which cross-vendor replication requires), assigns the target a distinct `server_id` if it collides with the source, and points MariaDB at the captured coordinates.

```
==> Binlog migration: configure and start replication
Ensuring replication user exists on source...
Applying replication coordinates: mysql-bin.000004:66378596
Replication started.
```

Verify

The tool polls replication status until both threads are running and lag is within `BINLOG_MAX_LAG_SECS` (default 30).

```
==> Binlog migration: verify replication
IO running: Yes
SQL running: Yes
Seconds behind master/source: 0
Replication verify passed.
```

There is no `ANALYZE TABLE` step in this mode, because replication keeps changing the tables after the seed.

Step 4: Confirm Changes Are Flowing

The target is now live-following the source, so a write on the source appears on the target within seconds. Inserting one row on the source and reading it back on the target confirms the pipeline end to end:

```
# on the source:
INSERT INTO sakila.film (title, language_id) VALUES ('LIVE REPLICATION TEST', 1);

# on the target, moments later:
+---------+-----------------------+
| film_id | title                 |
+---------+-----------------------+
|    1001 | LIVE REPLICATION TEST |
+---------+-----------------------+

# SHOW REPLICA STATUS on the target:
Master_Host: mysql.example.com
Seconds_Behind_Master: 0
```

Step 5: Cut Over

The tool stops after verification with replication running; the cutover is yours to perform when you are ready. The migrator does not stop replication or repoint your application for you. A safe cutover:

1. Stop application writes to the source. Put the application in maintenance mode or revoke write access so no new transactions are generated.
2. Wait for zero lag. Confirm `Seconds_Behind_Master: 0` on the target with `SHOW REPLICA STATUS\G`, so every committed source change has been applied.
3. Stop replication on the target with `STOP REPLICA;`, then `RESET REPLICA ALL;` once you are committed, to clear the replication configuration.
4. Repoint the application at the target MariaDB server and resume traffic.
5. Clean up the replication user on the source and any infrastructure accounts that were migrated.

Downtime is only the window between stopping writes on the source and resuming them on the target, which is short because the target is already caught up before you begin.

Reference

Beyond the common source and target variables, Replication requires `REPL_USER` and `REPL_PASS`. Optional variables include `SRC_BINLOG_FILE` and `SRC_BINLOG_POS` (auto-captured during the seed if unset), `BINLOG_MAX_LAG_SECS` (default 30), and `BINLOG_CREATE_REPL_USER` (default 1; set to 0 if the replication user already exists). See Environment Variables for the full list.

Other Modes

If Replication does not fit your situation, see the migrator overview to choose another mode: Serial Streaming Copy or Parallel Restartable Streaming Copy for an offline transfer when both servers are reachable, or Offline Copy when they are not.

Migrating to MariaDB from PostgreSQL

There are many different ways to migrate from PostgreSQL to MariaDB. This article will discuss some of those options.

MariaDB's CONNECT Storage Engine

MariaDB's CONNECT storage engine can be used to migrate from PostgreSQL to MariaDB. There are two primary ways that this can be done.

See Loading the CONNECT Storage Engine for information on how to install the CONNECT storage engine.

Tables with ODBC table_type

The CONNECT storage engine allows you to create tables that refer to tables on an external server, and it can fetch the data using a compatible ODBC driver. PostgreSQL does have a freely available ODBC driver called psqlODBC. Therefore, if you install `psqlODBC` on the MariaDB Server, and then configure the system's ODBC framework (such as unixODBC), then the MariaDB server will be able to connect to the remote PostgreSQL server. At that point, you can create tables with the ENGINE=CONNECT and table_type=ODBC table options set, so that you can access the PostgreSQL tables from MariaDB.

See CONNECT ODBC Table Type: Accessing Tables From Another DBMS for more information on how to do that.

Once the remote table is setup, you can migrate the data to local tables very simply. For example:

```
CREATE TABLE psql_tab (
   id INT,
   str VARCHAR(50)
) ENGINE = CONNECT
table_type=ODBC
tabname='tab'
CONNECTION='DSN=psql_server';

CREATE TABLE tab (
   id INT,
   str VARCHAR(50)
) ENGINE = InnoDB;

INSERT INTO tab SELECT * FROM psql_tab;
```

Tables with JDBC table_type

The CONNECT storage engine allows you to create tables that refer to tables on an external server, and it can fetch the data using a compatible JDBC driver. PostgreSQL does have a freely available JDBC driver. If you install this JDBC driver on the MariaDB server, then the MariaDB server will be able to connect to the remote PostgreSQL server via JDBC. At that point, you can create tables with the ENGINE=CONNECT and table_type=JDBC table options set, so that you can access the PostgreSQL tables from MariaDB.

See CONNECT JDBC Table Type: Accessing Tables from Another DBMS for more information on how to do that.

Once the remote table is setup, you can migrate the data to local tables very simply. For example:

```
CREATE TABLE psql_tab (
   id INT,
   str VARCHAR(50)
) ENGINE = CONNECT
table_type=JDBC
tabname='tab'
CONNECTION='jdbc:postgresql://psql_server/db1';

CREATE TABLE tab (
   id INT,
   str VARCHAR(50)
) ENGINE = InnoDB;

INSERT INTO tab SELECT * FROM psql_tab;
```

PostgreSQL's Foreign Data Wrappers

PostgreSQL's foreign data wrappers can also be used to migrate from PostgreSQL to MariaDB.

mysql_fdw

mysql_fdw allows you to create a table in PostgreSQL that actual refers to a remote MySQL or MariaDB server. Since MySQL and MariaDB are compatible at the protocol level, this should also support MariaDB.

The foreign data wrapper also supports writes, so you should be able to write to the remote MariaDB table to migrate your PostgreSQL data. For example:

```
CREATE TABLE tab (
   id INT,
   str text
);

INSERT INTO tab VALUES (1, 'str1');

CREATE SERVER mariadb_server
   FOREIGN DATA WRAPPER mysql_fdw
   OPTIONS (host '10.1.1.101', port '3306');

CREATE USER MAPPING FOR postgres
   SERVER mariadb_server
   OPTIONS (username 'foo', password 'bar');

CREATE FOREIGN TABLE mariadb_tab (
   id INT,
   str text
)
SERVER mariadb_server
OPTIONS (dbname 'db1', table_name 'tab');

INSERT INTO mariadb_tab SELECT * FROM tab;
```

PostgreSQL's COPY TO

PostgreSQL's COPY TO allows you to copy the data from a PostgreSQL table to a text file. This data can then be loaded into MariaDB with LOAD DATA INFILE.

MySQL Workbench

MySQL Workbench has a migration feature that requires an ODBC driver. PostgreSQL does have a freely available ODBC driver called psqlODBC.

See Set up and configure PostgreSQL ODBC drivers for the MySQL Workbench Migration Wizard for more information.

Known Issues

Migrating Functions and Procedures

PostgreSQL's functions and procedures use a language called PL/pgSQL. This language is quite different than the default `SQL/PSM` language used for MariaDB's stored procedures. `PL/pgSQL` is more similar to `PL/PSQL` from Oracle, so you may find it beneficial to try migrate with SQL_MODE=ORACLE set.

MariaDB / PostgreSQL Comparison

https://www.youtube.com/watch?v=l_5AgRPTa54

MariaDB and PostgreSQL: A technical deep-dive into how they differ (54 minutes • 2024)

This deep-dive explores the architectural and philosophy differences between MariaDB and PostgreSQL. It is particularly useful for users who are troubleshooting performance issues or deciding which database engine best suits their specific workload requirements.

Core Topics Covered:

- Storage Engine Architecture: Explains MariaDB's unique "pluggable storage engine" architecture (like InnoDB, MyRocks, and Aria) compared to PostgreSQL's single integrated storage engine approach.
- SQL Compatibility & Standards: A look at how PostgreSQL strictly adheres to SQL standards, whereas MariaDB prioritizes high performance and "pragmatic" features (like temporal tables and virtual columns).

- Concurrency Models: A comparison of how each handles multi-user traffic. The video highlights MariaDB's thread-pool approach versus PostgreSQL's process-per-connection model.
- JSON & Modern Data Types: How both databases have evolved to handle NoSQL-style data, comparing MariaDB's dynamic columns and JSON functions against PostgreSQL's JSONB.

Key Takeaway for Troubleshooting:

The video emphasizes that because MariaDB is a multi-engine database, connection or performance issues are often solved by tuning the specific engine being used (usually InnoDB) rather than the server as a whole – a major difference from the more "monolithic" troubleshooting approach in PostgreSQL.

Migrating to MariaDB from Oracle

See Oracle XE 11.2. and MariaDB 10.1 integration on Ubuntu 14.04 and Debian systems.

Migrate from Oracle to MariaDB Server. This page provides detailed guidance, tools, and best practices for a smooth and efficient transition of your databases and applications.

This page is licensed: CC BY-SA / Gnu FDL

Oracle XE 11.2. and MariaDB 10.1 integration on Ubuntu 14.04 and Debian systems

Part 1: Installing Oracle Database Express Edition (XE)

This section covers the installation of Java and the Oracle XE database on a Debian-based system like Ubuntu.

Step 1: Download Oracle Database XE

1. Sign up for an Oracle account (if you don't have one) and log in.
2. Navigate to the download page for legacy versions of the database. A good starting point is the Oracle Database Express Edition (XE) 11gR2 Archive Downloads Page.
3. Accept the license agreement.
4. Download Oracle Database Express Edition 11g Release 2 for Linux x64. The file will be named similarly to `oracle-xe-11.2.0-1.0.x86_64.rpm.zip`.

Step 2: Install and Configure Java 8

Oracle XE 11gR2 requires a Java environment.

A. Add the Java PPA and Install

```
sudo add-apt-repository ppa:webupd8team/java
# Press Enter to accept when prompted
sudo apt-get update
sudo apt-get install oracle-java8-installer
```

B. Verify Java Installation

After the installation completes, verify the version.

```
java -version
```

The output should be similar to:

```
java version "1.8.0_121"
```

C. Set JAVA_HOME Environment Variable

Edit the system-wide bash configuration file.

```
sudo nano /etc/bash.bashrc
```

Scroll to the bottom of the file and add the following lines:

```
export JAVA_HOME=/usr/lib/jvm/java-8-oracle
export PATH=$JAVA_HOME/bin:$PATH
```

Save the file and exit. Then, source the file to apply the changes and verify the variable is set.

```
source /etc/bash.bashrc
echo $JAVA_HOME
```

The output should be:

```
/usr/lib/jvm/java-8-oracle
```

Step 3: Install Prerequisite Packages

Additional packages are required to convert and install the Oracle RPM.

```
sudo apt-get install alien libaio1 unixodbc
```

Step 4: Convert the Oracle RPM to a DEB Package

The downloaded file is an RPM, which must be converted to a DEB package for Debian-based systems.

```
unzip oracle-xe-11.2.0-1.0.x86_64.rpm.zip
cd Disk1/
sudo alien --scripts -d oracle-xe-11.2.0-1.0.x86_64.rpm
```

> **Note:**
>
> This conversion step might take some time. You can proceed with the following configuration steps in a separate terminal window while it runs.

Step 5: Create `chkconfig` and Kernel Configuration

A. Create a `chkconfig` Compatibility Script

The Oracle installer expects the chkconfig utility, which doesn't exist on Debian-based systems. Create a compatibility script.

```
sudo nano /sbin/chkconfig
```

Add the following content to the new file:

```
#!/bin/bash
# Oracle 11gR2 XE installer chkconfig for Ubuntu
file=/etc/init.d/oracle-xe
if [[ ! `tail -n1 $file | grep INIT` ]]; then
  echo >> $file
  echo '### BEGIN INIT INFO' >> $file
  echo '# Provides: OracleXE' >> $file
  echo '# Required-Start: $remote_fs $syslog' >> $file
  echo '# Required-Stop: $remote_fs $syslog' >> $file
  echo '# Default-Start: 2 3 4 5' >> $file
  echo '# Default-Stop: 0 1 6' >> $file
  echo '# Short-Description: Oracle 11g Express Edition' >> $file
  echo '### END INIT INFO' >> $file
fi
update-rc.d oracle-xe defaults 80 01
#EOF
```

Save the file, then make it executable:

```
sudo chmod 755 /sbin/chkconfig
```

B. Configure Kernel Parameters

Create a configuration file for Oracle-specific kernel parameters.

```
sudo nano /etc/sysctl.d/60-oracle.conf
```

Copy and paste the following into the file. The value for `kernel.shmmax` should be approximately half of your system's physical RAM, specified in bytes (e.g., 512MB = 536870912 bytes).

```
# Oracle 11g XE kernel parameters
fs.file-max=6815744
net.ipv4.ip_local_port_range=9000 65000
kernel.sem=250 32000 100 128
kernel.shmmax=536870912
```

Apply the new kernel parameters and verify the `fs.file-max` setting.

```
sudo service procps start
sudo sysctl -q fs.file-max
```

The expected output is `6815744`.

Step 6: Final System Adjustments

A. Create Compatibility Links and Directories

```
sudo ln -s /usr/bin/awk /bin/awk
sudo mkdir /var/lock/subsys
sudo touch /var/lock/subsys/listener
```

B. Configure Shared Memory (/dev/shm)

To avoid a potential ORA-00845: MEMORY_TARGET error, re-mount the /dev/shm directory with a sufficient size. Replace 4096m with the amount of RAM on your machine.

```
sudo rm -rf /dev/shm
sudo mkdir /dev/shm
sudo mount -t tmpfs shmfs -o size=4096m /dev/shm
```

To make this change persistent across reboots, create a startup script.

```
sudo nano /etc/rc2.d/S01shm_load
```

Add the following content, again replacing `4096m` with your machine's RAM size.

```
#!/bin/sh
case "$1" in
start)
  mkdir /var/lock/subsys 2>/dev/null
  touch /var/lock/subsys/listener
  rm /dev/shm 2>/dev/null
  mkdir /dev/shm 2>/dev/null
  mount -t tmpfs shmfs -o size=4096m /dev/shm
  ;;
*)
  echo "Usage: $0 start"
  exit 1
  ;;
esac
```

Save the file and make it executable:

```
sudo chmod 755 /etc/rc2.d/S01shm_load
```

Step 7: Install and Configure Oracle XE

A. Install the Converted Package

By now, the .deb package should have been created. Install it using `\`.

```
sudo dpkg --install oracle-xe_11.2.0-2_amd64.deb
```

B. Run the Oracle Configuration Script

Configure the database by running the script and answering the prompts. The default answers are usually acceptable.

```
sudo /etc/init.d/oracle-xe configure
```

You will be prompted for:

- HTTP port for Oracle Application Express (default: `8080`)
- Database listener port (default: `1521`)
- A password for the `SYS` and `SYSTEM` accounts.
- Whether to start the database on boot (default: `y`)

C. Set Oracle Environment Variables

Edit `/etc/bash.bashrc` again to add the Oracle-specific variables.

```
sudo nano /etc/bash.bashrc
```

Add the following to the end of the file:

```
export ORACLE_HOME=/u01/app/oracle/product/11.2.0/xe
export ORACLE_SID=XE
export NLS_LANG=`$ORACLE_HOME/bin/nls_lang.sh`
export ORACLE_BASE=/u01/app/oracle
export LD_LIBRARY_PATH=$ORACLE_HOME/lib:$LD_LIBRARY_PATH
export PATH=$ORACLE_HOME/bin:$PATH
```

Apply and verify the changes:

```
source /etc/bash.bashrc
echo $ORACLE_HOME
```

D. Start Oracle

```
sudo service oracle-xe start
```

Part 2: Installing SQL Developer

Step 1: Download and Install SQL Developer

1. Go to the Oracle site and download the Linux RPM package for Oracle SQL Developer.
2. Use `alien` to convert the package and `dpkg` to install it.

```
sudo alien --scripts -d sqldeveloper-4.1.5.21.78-1.noarch.rpm
sudo dpkg --install sqldeveloper_4.1.5.21.78-2_all.deb
```

3. Create a configuration directory.

```
mkdir ~/.sqldeveloper
```

Step 2: Run and Connect to Oracle XE

1. Launch SQL Developer.

   Bash

   ```
   sudo /opt/sqldeveloper/sqldeveloper.sh
   ```

2. If it asks for the Java path, provide it: `/usr/lib/jvm/java-8-oracle`.
3. Inside SQL Developer, create a new connection with the following details:
   - Click: `Connections`, then `Add new connection`
   - Connection Name: `XE`
   - Username: `SYSTEM`
   - Password: `<your-password>`
   - Connection Type: `Basic`, Role: `Default`
   - Hostname: `localhost`
   - Port: `1521`
   - SID: `xe`

Part 3: Installing MariaDB and Connecting to Oracle

Step 1: Install MariaDB

Follow the official instructions on the MariaDB website for your specific OS version.

> **Important:**
>
> Do NOT copy the commands below. Go to the MariaDB Repository Configuration Tool to generate the correct commands for your system. The following is only an example.

```
# Example commands for Ubuntu 14.04 Trusty
sudo apt-get install software-properties-common
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xcbcb082a1bb943db
sudo add-apt-repository 'deb [arch=amd64,i386,ppc64el]
http://mirror.netinch.com/pub/mariadb/repo/10.1/ubuntu trusty main'
sudo apt-get update
sudo apt-get install mariadb-server
```

Step 2: Install MariaDB ODBC Connector

1. Download the “MariaDB Connector/ODBC” for Linux from the MariaDB website.
2. Extract the archive and copy the library file.

```
tar xfz mariadb-connector-odbc-2.0.13-ga-linux-x86_64.tar.gz
sudo cp -p mariadb-connector-odbc-2.0.13-ga-linux-x86_64/lib/libmaodbc.so /lib
sudo ldconfig
```

Step 3: Install UnixODBC and CONNECT Engine

```
sudo apt-get install unixodbc-dev unixodbc-bin unixodbc libodbc1 mariadb-connect-engine-10.1
```

Step 4: Configure ODBC Drivers

A. Configure the Oracle Driver

Edit `/etc/odbcinst.ini` and add the following section:

```
[Oracle ODBC driver for Oracle 11.2]
Description     = Oracle 11.2 ODBC driver
Driver          = /u01/app/oracle/product/11.2.0/xe/lib/libsqora.so.11.1
```

B. Configure the Oracle DSN

Edit `/etc/odbc.ini` and add a Data Source Name (DSN) for your Oracle XE database.

```
[XE]
Driver          = Oracle ODBC driver for Oracle 11.2
ServerName      = //localhost:1521/xe
DSN             = XE
UserName        = SYSTEM
Password        = <your-password>
```

Step 5: Test the Oracle ODBC Connection

Use `isql` to test the connection and create a sample table in Oracle.

```
isql -v XE SYSTEM <your-password>

CREATE TABLE t1 (i INT);
INSERT INTO t1 (i) VALUES (1);
INSERT INTO t1 (i) VALUES (3);
INSERT INTO t1 (i) VALUES (5);
INSERT INTO t1 (i) VALUES (8);
SELECT i FROM t1;
```

You should see the rows `1, 3, 5, 8` returned.

Step 6: Configure and Test the MariaDB CONNECT Engine

A. Set Environment Variables for MariaDB

For the CONNECT engine to find the Oracle libraries, you must add the Oracle environment variables to MariaDB's startup script. Edit /etc/init.d/mysql.

```
sudo nano /etc/init.d/mysql
```

Immediately after `### END INIT INFO`, add the following block:

```
# Oracle Environment for MariaDB CONNECT Engine
export JAVA_HOME=/usr/lib/jvm/java-8-oracle
export PATH=$JAVA_HOME/bin:$PATH
export ORACLE_HOME=/u01/app/oracle/product/11.2.0/xe
export CLIENT_HOME=$ORACLE_HOME
export ORACLE_SID=XE
export NLS_LANG=`$ORACLE_HOME/bin/nls_lang.sh`
export ORACLE_BASE=/u01/app/oracle
export LD_LIBRARY_PATH=$ORACLE_HOME/lib:$LD_LIBRARY_PATH
export PATH=$ORACLE_HOME/bin:$PATH
```

B. Restart MariaDB and Test the Connection

```
sudo /etc/init.d/mysql restart
mysql -uroot -p
```

Once logged into the MariaDB client, run the following SQL commands:

```
CREATE DATABASE mdb;
USE mdb;
INSTALL SONAME 'ha_connect';
CREATE TABLE t1 ENGINE=CONNECT TABLE_TYPE=ODBC tabname='T1' CONNECTION='DSN=XE;UID=SYSTEM;PWD=<your-
password>';

SELECT I FROM t1;
```

You should see the values `1, 3, 5, 8` retrieved from the Oracle table.

Part 4: Connecting to MariaDB via JDBC

Step 1: Install the MariaDB JDBC Driver

1. Download the "MySQL Connector/J" from the MySQL or MariaDB website.
2. Extract the archive and copy the `.jar` file to a known location.

```
tar xvfz mysql-connector-java-5.0.8.tar.gz
cd mysql-connector-java-5.0.8/
sudo mkdir -p /usr/lib/jvm/java-8-oracle/lib/mariadb/
sudo cp -p mysql-connector-java-5.0.8-bin.jar /usr/lib/jvm/java-8-oracle/lib/mariadb/
```

Step 2: Configure SQL Developer

1. Launch SQL Developer: `sudo /opt/sqldeveloper/sqldeveloper.sh`
2. Go to Tools -> Preferences.
3. Expand Database and click on Third Party JDBC Drivers.
4. Click Add Entry… and navigate to the `.jar` file you copied: `/usr/lib/jvm/java-8-oracle/lib/mariadb/mysql-connector-java-5.0.8-bin.jar`.
5. Click OK to close the preferences.

Step 3: Connect to MariaDB

1. In SQL Developer, create a new connection.

2. Switch to the MySQL tab.
3. Enter the connection details:
   - Connection Name: `MariaDB via MySQL Conn`
   - Username: `root`
   - Password: `<your-root-password>`
   - Hostname: `localhost`
   - Port: `3306`
4. Click Test Connection. It should report `Status: Success`.
5. Save and connect. You can now run queries against your MariaDB server in the worksheet.

MariaDB Backups Overview for SQL Server Users

MariaDB has the following types of backups:

- Logical backups (dumps).
- Hot backups with mariadb-backup.
- Snapshots.
- Incremental backups.

Logical Backups (Dumps)

A *dump*, also called a *logical backup*, consists of the SQL statements needed to recreate MariaDB databases and their data into another server. A dump is the slowest form of backup to restore, because it implies executing all the SQL statements needed to recreate data. However it is also the most flexible, because restoring will work on any MariaDB version, because the SQL syntax is usually compatible. It is even possible to restore a dump into an older version, though the incompatible syntax (new features) will be ignored. Under certain conditions, MariaDB dumps may also be restored on other DBMSs, including SQL Server.

The compatibility between different versions and technologies is achieved by using executable comments, but we should be aware of how they work. If we use a feature introduced in version 11.1, for example, it will be included in

the dump inside an executable comment. If we restore that backup on a server with MariaDB 10.11, the 11.1 feature will be ignored. This is the only way to restore backups in older MariaDB versions.

`mariadb-dump`

Logical backups are usually taken with mariadb-dump (previously called mysqldump).

mariadb-dump allows one to dump all databases, a single database, or a set of tables from a database. It is even possible to specify a `WHERE` clause, which under certain circumstances allows to obtain incremental dumps.

For consistency reasons, when using the default storage engine InnoDB, it is important to use the `--single-transaction` option. This will read all data in a single transaction. It's important however to understand that long transactions may have a big impact on performance.

The `--master-data` option adds the statements to setup a slave to the dump.

MariaDB also supports statements which make easy to write applications to obtain custom types of dumps. For most `CREATE <object_type>` statement, a corresponding `SHOW CREATE <object_type>` exists. For example, SHOW CREATE TABLE returns the `CREATE TABLE` statement that can be used to recreate a certain table, without data.

`mydumper`

mydumper is a 3rd party tools to take dumps from MariaDB and MySQL databases. It is much faster than `mariadb-dump` because it takes backups with several parallel threads, usually one thread for each available CPU core. It produces several files, that can be used to restore a database using the related tool myloader.

Since is it a 3rd party tool, it could be incompatible with some present or future MariaDB features.

Hot Backups (`mariadb-backup`)

`mariadb-backup` is a tool for taking a backup of MariaDB files while MariaDB is working. A lock is only held for a small amount of time, so it is suitable to backup a server without causing disruptions. It works by taking corrupted backups and then bringing them to a consistent state by using the InnoDB undo log. `mariadb-backup` also properly backups MyRocks tables and non-transactional storage engines.

Cold Backups and Snapshots

A copy of all MariaDB files is a working backup. Therefore, the easiest way to backup a dataset is to shutdown the server and copy all its files. It will be entirely possible to start another server with a copy of those files. This is often referred to as a *cold backup*. However, in most cases we don't want to do this, because it implies downtime for the server: it will not be working at least for the time necessary to copy the files.

Snapshots are usually a better idea, as they are a consistent copy of the files at a given moment in time, taken without stopping the normal operations.

A snapshot of the files can be taken at several levels: filesystem level, if the filesystem supports snapshots, for example `zfs`; Linux Logical Volume Manager (LVM) also supports snapshots; and virtual machines also allow one to take snapshots. Windows shadow copies are also snapshots, with a benefit: it is possible to restore a single file from a shadow copy. A snapshot is not an expensive operation, because it does not imply a copy of the files. The current files will not be modified anymore, and changes to them will be written in separate places.

The problem with snapshots is that they behave like a logical copy of the files as they are in a given point in time. But database files are not guaranteed to be consistent in every moment, because contents can be buffered before being flushed to the disk. You can think a database snapshot like a database after an operating system crash.

With non-transactional tables, some data is typically lost. Data changes that are present in a buffer before the snapshot, but not written on a disk, cannot be recovered in any way. Data changes in transactional tables, like

InnoDB tables, can always be recovered after restoring a snapshot (or after a crash), as long as a commit was done. Tables will still need to be repaired, just like it happens after an SQL Server crash.

Snapshots can be taken while MariaDB is running. To restore them, stop MariaDB first - or kill the process, because you don't really care of the consequences in this case. Then restore a snapshot and start MariaDB again.

For more information about snapshots, check your filesystem, LVM or virtual machine documentation.

Incremental Backups

The term incremental backup in MariaDB indicates what SQL Server calls a *differential backup*. An important difference is that in SQL Server such backups are based on the transaction log, which wouldn't be possible in MariaDB because transaction logs are handled at storage engine level.

As mentioned here, MariaDB can use the binary log instead for backup purposes. Such incremental backups can be done manually. This means that:

- The binary log files are copied just like any other regular file.
- To copy those files it is necessary to have the proper permissions at filesystem level, not in MariaDB.
- Backups do not expire until we delete the last needed complete backup.

Replaying the Binary Log

The page Using mariadb-binlog shows how to use the mariadb-binlog utility to replay a binary log file.

The page also shows how to edit the binary log before replaying it. This allows one to undo an SQL statement that was executed by mistake, for example a `DROP TABLE` against a wrong table. The high level procedure is the following:

- Restore a backup that is older than the SQL statement to undo.
- Use `mariadb-binlog` to generate a file with the SQL statements that were executed after the backup.
- Edit the SQL file, erasing the unwanted statement.
- Run the SQL file.

Incremental Backups with mariadb-backup

The simplest way to take an incremental backup is to use mariadb-backup. This tool is able to take and restore incremental backups. For the complete procedure to use, see Incremental Backup and Restore with mariadb-backup.

mariadb-backup can run on both Linux and Windows systems.

Flashback

Flashback is a feature that allows one to bring all databases, some databases or some tables back to a certain point in time. This can only be done if the binary log is enabled. Flashback is not a proper backup, but it can be used to restore a certain set of data.

Copying Individual Tables

It is entirely possible to restore a single table from a physical backup, or to copy the table to another server.

With the MyISAM storage engine it was very easy to move tables between different servers, as long as the MySQL or MariaDB version was the same.

InnoDB is nowadays the default storage engine, and it is more complex, as it supports transactions for example. It still supports restoring a table from a physical file, this feature is called *transportable tablespaces*. There is a

particular procedure to follow, and some limitations. This is basically the MariaDB equivalent of detaching and re-attaching tables in SQL Server.

For more information, see InnoDB File-Per-Table Tablespaces.

By default. all table files are located in the *data directory*, which is defined by the system variable datadir. There may be exceptions, because a table's files can be located elsewhere using the DATA DIRECTORY and INDEX DIRECTORY options in `CREATE TABLE`.

Regardless of the storage engine used, each table's structure is generally stored in a file with the `.frm` extension.

The files used for partitioned tables are different from the files used for non-partitioned tables. See Partitions Files for details.

Understanding MariaDB Architecture

MariaDB architecture is partly different from the architecture of traditional DBMSs, like SQL Server. Here we will examine the main components that a new MariaDB DBA needs to know. We will also discuss a bit of history, because this may help understand MariaDB philosophy and certain design choices.

This section is an overview of the most important components. More information is included in specific sections of this migration guide, or in other pages of the MariaDB documentation (see the links scattered over the text).

Storage Engines

MariaDB was born from the source code of MySQL, in 2008. Therefore, its history begins with MySQL.

MySQL was born at the beginning of the 90s. Back in the days, if compared to its existing competitors, MySQL was lightweight, simple to install, easy to learn. While it had a very limited set of features, it was also fast in certain common operations. And it was open source. These characteristics made it suitable to back the simple websites that existed at that time.

The web evolved rapidly, and the same happened to MySQL. Being open source helped a lot in this respect, because the community needed functionalities that weren't supported at that time.

MySQL was probably the first database system to support a pluggable storage engine architecture. Basically, this means that MySQL knows very little about creating or populating a table, reading from it, building proper indexes and caches. It just delegated all these operations to a special plugin type called a storage engine.

One of the first plugins developed by third parties was InnoDB. It is very fast, and it adds two important features that are not otherwise supported: transactions and foreign keys.

Note that when MariaDB asks a storage engine to write or read a row, the storage engine could theoretically do anything. This led to the creation of very interesting alternative engines, like BLACKHOLE (which doesn't write or read any data, acting like the /dev/null file in Linux), or CONNECT (which can read and write to files written in many different formats, or remote DBMSs, or some other special data sources).

Nowadays InnoDB is the default MariaDB storage engine, and it is the best choice for most use cases. But for particular needs, sometimes using a different storage engine is desirable. In case of doubts about the best storage engine to use for a specific case, check the Choosing the Right Storage Engine page.

When we create a table, we specify its storage engine or use the default one. It is possible to convert an existing table to another storage engine, though this is a blocking operation which requires a complete table copy. Third-party storage engines can also be installed while MariaDB is running.

Note that it is perfectly possible to use tables with different storage engines in the same transaction (even if some engines are not transactional). It is even possible to use different engines in the same query, for example with JOINs

and subqueries.

The default storage engine can be changed by changing the default_storage_engine variable. A different default can be specified for temporary tables by setting default_tmp_storage_engine. MariaDB uses Aria for system tables and temporary tables created internally to store the intermediate results of a query.

InnoDB

It is worth spending some more words here about InnoDB, the default storage engine.

Primary Key and Indexes

InnoDB primary keys are always the equivalent of SQL Server clustered indexes. In other words, an InnoDB table is always ordered by the primary key.

If an InnoDB table doesn't have a user-defined primary key, the first `UNIQUE` index whose columns are all `NOT NULL` is used as a primary key. If there is no such index, the table will have a *clustered index*. The terminology here can be a bit confusing for SQL Server and other DBMS users. A clustered index in InnoDB is a 6 bytes value that is added to the table. This index and its values are completely invisible to the users. It's important to note that clustered indexes are governed by a global mutex that greatly reduces their scalability.

Secondary indexes are ordered by the columns that are part of the index, and contain a reference to each entry's corresponding primary key value.

Some consequences of these design choices are the following:

- For performance reasons, a primary key value should be inserted in order. In other words, the last inserted value should be the highest. This order is normally followed when inserting values into an `AUTO_INCREMENT` primary key. The reason is that inserting values in the middle of an ordered data structure is slower, unless they fit into existing holes. If we insert primary key values randomly, InnoDB often has to rearrange pages to make some room for the new data.
- A big primary keys means that all secondary indexes are also big.
- A query by primary key will require a single search. A query on a secondary index that also reads columns not contained in the index will require one search on the index, plus one more search for each row that satisfies the index condition.
- We shouldn't explicitly include the primary key in a secondary index. If we do so, the primary key column will be duplicated in the index.

Tablespaces

For InnoDB, a *tablespace* is a file containing data (not a file group as in SQL Server). The types of tablespaces are:

- System tablespace.
- File-per-table tablespaces.
- Temporary tablespaces.

The system tablespace is stored in the file `ibdata`. It contains information used by InnoDB internally, like rollback segments, as well as some system tables. Historically, the system tablespace also contained all tables created by the user. In modern MariaDB versions, a table is created in the system tablespace only if the innodb_file_per_table system variable is set to 0 at the moment of the table creation. By default, innodb_file_per_table is 1.

Tables created while `innodb_file_per_table=1` are written into their own tablespace. These are `.ibd` files.

Starting from MariaDB 10.2, temporary tables are written into temporary tablespaces, which means `ibtmp*` files. Previously, they were created in the system tablespace or in file-per-table tablespaces according to the value of `innodb_file_per_table`, just like regular tables. Temporary tablespaces, if present, are deleted when MariaDB starts.

It is important to remember that tablespaces can never shrink. If a file-per-table tablespace grows too much, deleting data won't recover space. Instead, a new table must be created and data needs to be copied. Finally, the old table will be deleted. If the system tablespace grows too much, the only solution is to move data into a new MariaDB installation.

Transaction Logs

In SQL Server, the transaction log contains both the undo log and the redo log. Usually we have only one transaction log.

In MariaDB the undo log and the redo log are stored separately. By default, the redo log is written to two files, called `ib_logfile0` and `ib_logfile1`. The undo log by default is written to the *system tablespace*, which is in the `ibdata1` file. However, it is possible to write it in separate files in a specified directory.

MariaDB provides no way to inspect the contents of the transaction logs. However, it is possible to inspect the binary log.

InnoDB transaction logs are written in a circular fashion: their size is normally fixed, and when the end is reached, InnoDB continues to write from the beginning. However, if very long transactions are running, InnoDB cannot overwrite the oldest data, so it has to expand the log size instead.

InnoDB Buffer Pool

MariaDB doesn't have a central buffer pool. Each storage engine may or may not have a buffer pool. The InnoDB buffer pool is typically assigned a big amount of memory. See MariaDB Memory Allocation.

MariaDB has no extension like the SQL Server buffer pool extension.

A part of the buffer pool is called the change buffer. It contains dirty pages that have been modified in memory and not yet flushed.

InnoDB Background Threads

InnoDB has background threads that take care of flushing dirty pages from the change buffer to the tablespaces. They don't directly affect the latency of queries, but they are very important for performance.

SHOW ENGINE InnoDB STATUS shows information about them in the `BACKGROUND THREAD` section. They can also be seen using the threads table, in the performance_schema.

InnoDB flushing is similar to *lazy writes* and *checkpoints* in SQL Server. It has no equivalent for *eager writing*.

For more information, see InnoDB Page Flushing and InnoDB Purge.

Checksums and Doublewrite Buffer

InnoDB pages have checksums. After writing pages to disk, InnoDB verifies that the checksums match. The checksum algorithm is determined by innodb_checksum_algorithm. Check the variable documentation for its consequences on performance, backward compatibility and encryption.

In case of a system crash, hardware failure or power outage, a page could be half-written on disk. For some pages, this causes a disaster. Therefore, InnoDB writes essential pages to disk twice. A backup copy of the new page version is written first. Then, the old page is overwritten. The backup copies are written into a file called the *doublewrite buffer*.

- If an event prevents the first page from being written, the old version of the page will still be available.
- If an event prevents the old page from being completely overwritten by its new version, the page can still be recovered using the doublewrite buffer.

The doublewrite buffer can disabled using the innodb_doublewrite variable, but this usually doesn't bring big performance benefits. The doublewrite buffer location can be changed with innodb_doublewrite_file.

Aria

Even if we only create InnoDB tables, we use Aria indirectly, in two ways:

- For system tables.
- For internal temporary tables.

Aria is a non-transactional storage engine. By default it is crash-safe, meaning that all changes to data are durably written to a write-ahead log and can always be recovered in case of a crash.

Aria caches indexes into the pagecache. Data are not directly cached by Aria, so it's important that the underlying filesystem caches reads and writes.

The pagecache size is determined by the aria_pagecache_buffer_size system variable. To know if it is big enough we can check the proportion of free pages (the ratio between Aria_pagecache_blocks_used and Aria_pagecache_blocks_unused) and the proportion of cache misses (the ratio between Aria_pagecache_read_requests and Aria_pagecache_reads.

The proportion of dirty pages is the ratio between Aria_pagecache_blocks_used and Aria_pagecache_blocks_not_flushed tells us if the log file is big enough.

The size of Aria log is determined by aria_log_file_size.

Databases

MariaDB does not support the concept of schema. In MariaDB SQL, *schema* and *schemas* are synonyms for *database* and *databases*.

When a user connects to MariaDB, they don't connect to a specific database. Instead, they can access any table they have permissions for. There is however a concept of *default database*, see below.

A database is a container for database objects like tables and views. A database serves the following purposes:

- A database is a namespace.
- A database is a logical container to separate objects.
- A database has a default character set and collation, which are inherited by their tables.
- Permissions can be assigned on a whole database, to make permission maintenance simpler.
- Physical data files are stored in a directory which has the same name as the database to which they belong.

System Databases

MariaDB has the following system databases:

- mysql is for internal use only, and should not be read or written directly.
- information_schema contains all information that can be found in SQL Server's information_schema and more. However, while SQL Server's `information_schema` is a schema containing information about the local database, MariaDB's `information_schema` is a database that contains information about all databases.
- performance_schema contains information about MariaDB runtime. It is disabled by default. Enabling it requires setting the performance_schema system variable to 1 and restarting MariaDB.

Default Database

When a user connects to MariaDB, they can optionally specify a default database. A default database can also be specified or changed later, with the USE command.

Having a default database specified allows one to specify tables without specifying the name of the database where they are located. If no default database is specified, all table names must be fully qualified.

For example, the two following snippets are equivalent:

```
SELECT * FROM my_database.my_table;

-- is equivalent to:
USE my_database;
SELECT * FROM my_table;
```

Even if a default database is specified, tables from other databases can be accessed by specifying their fully qualified names:

```
-- this query joins my_database.my_table to your_database.your_table
USE my_database;
SELECT m.*
    FROM my_table m
    JOIN your_database.your_table y
        ON m.xyz = y.xyz;
```

MariaDB has the DATABASE() function to determine the current database:

```
SELECT DATABASE();
```

Stored procedures and triggers don't inherit a default database from the session, nor by a caller procedure. In that context, the default database is the database which contains the procedure. `USE` can be used to change it. The default database will only be valid for the rest of the procedure.

The Binary Log

Different tables can be built using different storage engines. It is important to note that not all engines are transactional, and that different engines implement the transaction logs in different ways. For this reason, MariaDB cannot replicate data from a primary to a replica using an equivalent of SQL Server transactional replication.

Instead, it needs a global mechanism to log the changes that are applied to data. This mechanism is the binary log, often abbreviated to binlog.

The binary log can be written in the following formats:

- STATEMENT logs SQL statements that modify data;
- ROW logs a reference to the rows that have been modified, if any (usually it's the primary key), and the new values that have been added or modified, in a binary format.
- MIXED is a combination of the above formats. It means that ROW is used for statements that can safely be logged in this way (see below), and STATEMENT is used in other cases. This is the default format from MariaDB 10.2.

In most cases, STATEMENT is slower because the SQL statement needs to be re-executed by the replica, and because certain statements may produce a different result in the replica (think about queries that use LIMIT without ORDER BY, or the CURRENT_TIMESTAMP() function). But there are exceptions, and besides, DDL statements are always logged as STATEMENT to avoid flooding the binary log. Therefore, the binary log may well contain both ROW and STATEMENT entries.

See Binary Log Formats.

The binary log allows:

- replication, if enabled on the primary;
- promoting a replica to a primary, if enabled on that replica;

- incremental backups;
- seeing data as they were in a point of time in the past (flashback);
- restoring a backup and re-appling the binary log, with the exception of a data change which caused problems (human mistake, application bug, SQL injection);
- Capture Data Changes (CDC), by streaming the binary log to technologies like Apache Kafka.

If you don't plan to use any of these features on a server, it is possible to disable the binary log to slightly improve the performance.

The binary log can be inspected using the mariadb-binlog utility, which comes with MariaDB. Enabling or disabling the binary log requires restarting MariaDB.

See also MariaDB Replication Overview for SQL Server Users and MariaDB Backups Overview for SQL Server Users for a better understanding of how the binary log is used.

Plugins

Storage engines are a special type of plugin. But others exist. For example, plugins can add authentication methods, new features, SQL syntax, functions, informative tables, and more.

A plugin may add some server variables and some status variables. Server variables can be used to configure the plugin, and status variables can be used to monitor its activities and status. These variables generally use the plugin's name as a prefix. For example InnoDB has a server variable called innodb_buffer_pool_size to configure the size of its buffer pool, and a status variable called Innodb_pages_read which indicates the number of memory pages read from the buffer pool. The category system variables of the MariaDB documentation has specific pages for system and status variables associated with various plugins.

Many plugins are installed by default, or available but not installed by default. They can be installed or uninstalled at runtime with SQL statements, like `INSTALL PLUGIN`, `UNINSTALL PLUGIN` and others; see Plugin SQL Statements. 3rd party plugins can be made available for installation by simply copying them to the plugin_dir.

It is important to note that different plugins may have different maturity levels. It is possible to prevent the installation of plugins we don't consider production-ready by setting the plugin_maturity system variable. For plugins that are distributed with MariaDB, the maturity level is determined by the MariaDB team based on the bugs reported and fixed.

Some plugins are developed by 3rd parties. Even some 3rd party plugins are included in MariaDB official distributions - the ones available on mariadb.org.

In MariaDB every authorization method (including the default one) is provided by an authentication plugin. A user can be required to use a certain authentication plugin. This gives us much flexibility and control. Windows users may be interested in gsapi (which supports Windows authentication, Kerberos and NTLM) and named_pipe (which uses named pipe impersonation).

Other plugins that can be very useful include userstat, which includes statistics about resources and table usage, and METADATA_LOCK_INFO, which provides information about metadata locks.

Thread Pool

MariaDB supports thread pool. It works differently on UNIX and on Windows. On Windows, it is enabled by default and its implementation is quite similar to SQL Server. It uses the Windows native CreateThreadpool API.

If we don't use the thread pool, MariaDB will use its traditional method to handle connections. It consists of using a dedicated thread for each client connection. Creating a new thread has a cost in terms of CPU time. To mitigate this cost, after a client disconnects, the thread may be preserved for a certain time in the thread cache.

Whichever connection method we use, MariaDB has a maximum number of simultaneous connections, which can be changed at runtime. When the limit is reached, if more clients try to connect they will receive an error. This prevents MariaDB from consuming all the server resources and freezing or crashing. See Handling Too Many Connections.

Configuration

MariaDB has many settings that control the server behavior. These can be set up when starting mysqld (mysqld options), and the vast majority are also accessible as server system variables. These can be classified in these ways:

- Dynamic or static;
- Global, session, or both.

Note that server system variables are not to be confused with user-defined variables. The latter are not used for MariaDB configuration.

Configuration Files

MariaDB can use several configuration files. Configuration files are searched in several locations, including in the user directory, and if present they all are read and used. They are read in a consistent order. These locations depend on the operating system; see Default Option File Locations. It is possible to tell MariaDB which files it should read; see Global Options Related to Option Files.

On Linux, by default the configuration files are called `my.cnf`. On Windows, by default the configuration files can be called `my.ini` or `my.cnf`. The former is more common.

If a variable is mentioned multiple times in different files, the occurrence that is read last will overwrite the others. Similarly, if a variable is mentioned several times in a single file, the occurrence that is read last overwrites the others.

The contents of each configuration file are organized by *option groups*. MariaDB Server and client programs read different groups. The read groups also depend on the MariaDB version. See Option Groups for the details. Most commonly, the `[server]` or `[mysqld]` groups are used to contain all server configuration. The `[client-server]` group can be used for options that are shared by the server and the clients (like the port to use), to avoid repeating those variables multiple times.

Dynamic and Static Variables

Dynamic variables have a value that can be changed at runtime, using the SET SQL statement. Static variables have a value that is decided at startup (see below) and cannot be changed without a restart.

The Server System Variables page states if variables are dynamic or static.

Scope

A global system variable is one that affects the general behavior of MariaDB. For example innodb_buffer_pool_size determines the size of the InnoDB buffer pool, which is used by read and write operations, no matter which user issued them. A session system variable is one that affects MariaDB behavior for the current connection; changing it will not affect other connected users, or future connections from the current user.

A variable could exist in both the global and session scopes. In this case, the session value is what affects the current connection. When a user connects, the current global value is copied to the session scope. Changing the global value afterward will not change existing connections.

The Server System Variables page states the scope of each variable.

Global variables and some session variables can only be modified by a user with the SUPER privilege (typically root).

Syntax

To see the value of a system variable:

```
-- global variables:
SELECT @@global.variable_name;
-- session variables:
SELECT @@session.variable_name;
-- or just use the shortcut:
SELECT @@variable_name;
```

A longer syntax, which is mostly useful to get multiple variables, makes use of the same pattern syntax that is used by the LIKE operator:

```
-- global variables whose name starts with 'innodb':
SHOW GLOBAL VARIABLES LIKE 'innodb%';
-- session variables whose name starts with 'innodb':
SHOW SESSION VARIABLES LIKE 'innodb%';
SHOW VARIABLES LIKE 'innodb%';
```

To modify the global or session value of a dynamic variable:

```
SET @@global.variable_name = 'new 'value';
SET @@session.variable_name = 'new 'value';
```

Notice that if we modify a global variable in this way, the new value will be lost at server restart. For this reason we probably want to change the value in the configuration file too.

For further information see:

- The SET statement.
- The SHOW VARIABLES statement.

Setting System Variables with Startup Parameters

System variables can be set at server startup without writing their values into a configuration file. This is useful if we want a value to be set once, until we change it or restart MariaDB. Values passed in this way override values written in the configuration files.

The general rule is that every global variable can be passed as an argument of `mysqld` by prefixing its name with `--` and by replacing every occurrence of `_` with `-` in its name.

For example, to pass `bind_address` as a startup argument:

```
mysqld --bind-address=127.0.0.1
```

Debugging Configuration

Mistyping a variable can prevent MariaDB from starting. We cannot set a variable that doesn't exist in the MariaDB version in use. In these cases, an error is written in the error log.

Having several configuration files and configuration groups, as well as being able to pass variables as command-line arguments, brings a lot of flexibility but can sometimes be confusing. When we are unsure about which values will be used, we can run:

```
mysqld --print-defaults
```

Status Variables

MariaDB status variables and some system tables allow external tools to monitor a server, building graphs on how they change over time, and allow the user to inspect what is happening inside the server.

Status variables cannot be directly modified by the user. Their values indicate how MariaDB is operating. Their scope can be:

- Global, meaning that the value is about some MariaDB activity.
- Session, meaning that the value measures activities taking place in the current session.

Many status variables exist in both scopes. For example,Cpu_time at global level indicates how much time the CPU was used by the MariaDB process (including all user sessions and all the background threads). At session level, it indicates how much time the CPU was used by the current session.

The status variables created by a plugin, usually, use the plugin name as a prefix.

The SHOW STATUS statement prints the values of the status variables that match a certain pattern.

```
-- Show all InnoDB global status variables
SHOW GLOBAL STATUS LIKE 'innodb%';
-- Show all InnoDB session status variables
SHOW SESSION STATUS LIKE 'innodb%';
SHOW STATUS LIKE 'innodb%';
-- Show global variables that contain the "size" substring:
SHOW GLOBAL STATUS LIKE '%size%';
```

Some status variables values are reset when FLUSH STATUS is executed. A possible use:

```
DELIMITER ||
BEGIN NOT ATOMIC
SET @i = 0;
WHILE @i < 60 DO
    SHOW GLOBAL STATUS LIKE 'Com_select';
    FLUSH STATUS;
    DO SLEEP(1);
    SET @i = @i + 1;
END WHILE;
END ||
```

This page is licensed: CC BY-SA / Gnu FDL

MariaDB Features Not Available in SQL Server

Some MariaDB features are not available in SQL Server.

At first glance, it is not important to know about those features to migrate from SQL Server to MariaDB. However, this is not the case. Using MariaDB features that are not in SQL Server allows one to obtain more advantages from the migration, getting the most from MariaDB.

This page has a list of MariaDB features that are not supported in SQL Server. The list is not exhaustive.

Plugin Architecture

- Storage engines.
- Authentication plugins.
- Encryption plugins.
- ColumnStore is a columnar storage engine designed to scale horizontally. It runs on a specific edition of MariaDB, so currently it cannot be used in combination with other engines.

SQL

- The sql_mode variable determines in which cases an SQL statement should fail with an error, and in which cases it should succeed with a warning even if it is not entirely correct. For example, when a statement tries to insert a string in a column which is not big enough to contain it, it could fail, or it could insert a truncated string and emit a warning. It is a tradeoff between reliability and flexibility.
  - SQL_MODE=MSSQL allows one to use a small subset of SQL Server proprietary syntax.
- The CREATE … IF EXISTS, CREATE OR REPLACE, DROP … IF NOT EXISTS options are supported for most DDL statements.
- SHOW statements.
- SHOW CREATE statements.
- SHOW PROCESSLIST and PERFORMANCE_SCHEMA THREAD table provide much richer information, compared to SQL Server `sp_who()` and `sp_who2()` procedures.
- CHECKSUM TABLE statement.
- PL/SQL support (only for stored procedures and stored functions).
- Row constructors.
- `BEFORE` triggers.
- HANDLER statements, to scroll table rows ordered by an index or in their physical order.
- DO statement, to call functions without returning a result set.
- BENCHMARK() function, to measure the speed of an SQL expression.

See also Syntax Differences between MariaDB and SQL Server.

Types

- Character sets and collations don't depend on column type. They can be set globally, or at database, table or column level.
- Columns may use non-constant expressions as the DEFAULT value. TIMESTAMP columns may have a `DEFAULT` value.
- UNSIGNED numeric types.
- Dynamic columns (note that JSON is usually preferred to this feature).

See also SQL Server and MariaDB Types Comparison.

JSON

For compatibility with some other database systems, MariaDB supports the JSON pseudo-type. However, it is just an alias for:

```
LONGTEXT CHECK (JSON_VALID(column_name))
```

JSON_VALID() is the MariaDB equivalent of SQL Server's `ISJSON()`.

Features

- Flashback functionality allows one to "undo" the changes that happened after a certain point in time.
- Partitioned tables support the following features:
  - Tables can be partitioned based on multiple columns.
  - Several partitioning types are available.
  - Subpartitions.
- Progress reporting for some typically expensive statements.

This page is licensed: CC BY-SA / Gnu FDL

SQL Server Features Not Available in MariaDB

When planning a migration between different DBMSs, one of the most important aspects to consider is that the new database system will probably miss some features supported by the old one. This is not relevant for all users. The most widely used features are supported by most DBMSs. However, it is important to make a list of unsupported features and check which of them are currently used by applications. In most cases it is possible to implement such features on the application side, or simply stop using them.

This page has a list of SQL Server features that are not supported in MariaDB. The list is not exhaustive.

Introduced in SQL Server versions older than 2016

- Full outer joins.
- `GROUP BY CUBE` syntax.
- `MERGE` statement.
- In MariaDB, indexes are always ascending. Defining them as `ASC` or `DESC` has no effect.
  - For single-column indexes, the performance difference between an `ORDER BY ... ASC` and `DESC` is negligible.
  - For multiple-column indexes, an index may be unusable for certain queries because `DESC` is not supported. In some cases, a generated column can be used to invert the order of an index (for example, the expression `0 - price` can be indexed to index the prices in a descending order).
- The WITH syntax is currently only supported for the `SELECT` statement.
- Filtered indexes (`CREATE INDEX ... WHERE`).
- Autonomous transactions.
- User-defined types.
- Rules.
- Triggers don't support the following features:
  - Triggers on DDL and login.
  - `INSTEAD OF` triggers.
  - The `DISABLE TRIGGER` syntax.
- Cursors advanced features.
  - Global cursors.
  - `DELETE ... CURRENT OF`, `UPDATE ... CURRENT OF` statements: MariaDB cursors are read-only.
  - Specifying a direction (MariaDB cursors can only advance by one row).
- Synonyms.
- Table variables.
- Queues.
- XML indexes, XML schema collection, XQuery.
- User access to system functionalities, for example:
  - Running system commands (`xp_cmdshell()`).
  - Sending emails (`sp_send_dbmail()`).
  - Sending HTTP requests.
- External languages, external libraries (MariaDB only supports procedural SQL and PL/SQL).
- Negative permissions (the `DENY` command).
- Snapshot replication. See Provisioning a Slave.

Introduced in SQL Server 2016

- Native data masking
- PolyBase (however, MariaDB 10.5 supports accessing Amazon S3 via the S3 storage engine and several DBMSs via CONNECT)
- R and Python services
- ColumnStore indexes. MariaDB has a storage engine called ColumnStore, but this is a completely different feature.

Introduced in SQL Server 2017

- Adaptive joins
- Graph SQL

SQL Server Features Implemented Differently in MariaDB

Modern DBMSs implement several advanced features. While an SQL standard exists, the complete feature list is different for every database system. Sometimes different features allow achieving the same purpose, but with a different logic and different limitations. This is something to take into account when planning a migration.

Some features are implemented by different DBMSs, with a similar logic and similar syntax. But there could be important differences that users should be aware of.

This page has a list of SQL Server features that MariaDB implements in a different way, and SQL Server features for which MariaDB has an alternative feature. Minor differences are not taken into account here. The list is not exhaustive.

SQL

- The list of supported data types is different.
- There are relevant differences in transaction isolation levels.
- `SNAPSHOT` isolation level is not supported. Instead, you can use `START TRANSACTION WITH CONSISTENT SNAPSHOT` to acquire a snapshot at the beginning of the transaction. This is compatible with all isolation levels. See How Isolation Levels are Implemented in MariaDB.
- JSON support is different.

Indexes and Performance

- Clustered indexes. In MariaDB, the physical order of rows is delegated to the storage engine. InnoDB uses the primary key as a clustered index.
- Hash indexes. Only some storage engines support `HASH` indexes.
  - The InnoDB storage engine has a feature called adaptive hash index, enabled by default. It means that in InnoDB all indexes are created as `BTREE`, and depending on how they are used, InnoDB could convert them from BTree to hash indexes, or the other way around. This happens in the background.
  - The MEMORY storage engine uses hash indexes by default, if we don't specify the `BTREE` keyword.
  - See Storage Engine Index Types for more information.
- Query store. MariaDB allows query performance analysis using the slow log and performance_schema. Some open source or commercial 3rd party tools read that information to produce statistics and make it easy to identify slow queries.

Tables

- Computed columns are called generated columns in MariaDB and are created with a different syntax. See also Implementation Differences Compared to Microsoft SQL Server.
- Temporal tables use a different (more standard) syntax on MariaDB. In MariaDB, the history is stored in the same table as current data (but optionally in different partitions). MariaDB supports both SYSTEM_TIME and APPLICATION_TIME.
- Hidden columns are Invisible columns in MariaDB.
- Temporary tables are implemented and used differently.

High Availability

- `NOT FOR REPLICATION`
  - MariaDB supports replication filters to exclude some tables or databases from replication
  - It is possible to keep a table empty in a slave (or in the master) by using the BLACKHOLE storage engine.
  - The master can have columns that are not present in a slave (the other way around is also supported). Before using this feature, carefully read the Replication When the Master and Slave Have Different Table Definitions page.
  - With MariaDB it's possible to prevent a trigger from running on slaves.
  - It's possible to run events without replicating them. The same applies to some administrative statements.
  - MariaDB superusers can run statements without replicating them, by using the sql_log_bin system variable.
  - Constraints and triggers cannot be disabled for replication, but it is possible to drop them on the slaves.
  - The `IF EXISTS` syntax allows one to easily create a table on the master that already exists (possibly in a different version) on a slave.
- pollinginterval option. See Delayed Replication.

Security

- The list of permissions is different.
- Security policies. MariaDB allows one to achieve the same results by assigning permissions on views and stored procedures. However, this is not a common practice and it's more complicated than defining security policies. See Other Uses of Views.
- MariaDB does not support an `OUTPUT` clause. Instead, we can use DELETE RETURNING and, since MariaDB 10.5, INSERT RETURNING and REPLACE RETURNING.

Other Features

- Linked servers. MariaDB supports storage engines to read from, and write to, remote tables. When using the CONNECT engine, those tables could be in different DBMSs, including SQL Server.
- Job scheduler: MariaDB uses an event scheduler to schedule events instead.

SQL Server and MariaDB Types Comparison

This page helps to map each SQL Server type to the matching MariaDB type.

Numbers

In MariaDB, numeric types can be declared as `SIGNED` or `UNSIGNED`. By default, numeric columns are `SIGNED`, so not specifying either will not break compatibility with SQL Server.

When using `UNSIGNED` values, there is a potential problem with subtractions. When subtracting an `UNSIGNED` valued from another, the result is usually of an `UNSIGNED` type. But if the result is negative, this will cause an error. To solve this problem, we can enable the NO_UNSIGNED_SUBTRACTION flag in sql_mode.

For more information see Numeric Data Type Overview.

Integer Numbers

SQL Server Types	Size (bytes)	MariaDB Types	Size (bytes)	Notes
tinyint	1	TINYINT	1	
smallint	2	SMALLINT	2	
		MEDIUMINT	3	Takes 3 bytes on disk, but 4 bytes in memory
int	4	INT / INTEGER	4	
bigint	8	BIGINT	8	

Real Numbers (approximated)

SQL Server Types	Precision	Size	MariaDB Types	Size
float(1-24)	7 digits	4	FLOAT(0-23)	4
float(25-53)	15 digits	8	FLOAT(24-53)	8

MariaDB supports an alternative syntax: `FLOAT(M, D)`. M is the total number of digits, and D is the number of digits after the decimal point.

See also: Floating-point Accuracy.

Aliases

In SQL Server `real` is an alias for `float(24)`.

In MariaDB DOUBLE, and DOUBLE PRECISION are aliases for `FLOAT(24-53)`.

Normally, `REAL` is also a synonym for `FLOAT(24-53)`. However, the sql_mode variable can be set with the `REAL_AS_FLOAT` flag to make `REAL` a synonym for `FLOAT(0-23)`.

Real Numbers (Exact)

SQL Server Types	Precision	Size (bytes)	MariaDB Types	Precision	Size (bytes)
decimal	0 - 38	Up to 17	DECIMAL	0 - 38	See table

MariaDB supports this syntax: `DECIMAL(M, D)`. M and D are both optional. M is the total number of digits (10 by default), and D is the number of digits after the decimal point (0 by default). In SQL Server, defaults are 18 and 0, respectively. The reason for this difference is that SQL standard imposes a default of 0 for D, but it leaves the implementation free to choose any default for M.

SQL Server `DECIMAL` is equivalent to MariaDB `DECIMAL(18)`.

Aliases

The following aliases for `DECIMAL` are recognized in both SQL Server and MariaDB: `DEC`, `NUMERIC`. MariaDB also allows one to use `FIXED`.

Money

SQL Server `money` and `smallmoney` types represent real numbers guaranteeing a very low level of approximation (five decimal digits are accurate), optionally associated with one of the supported currencies.

MariaDB doesn't have monetary types. To represent amounts of money:

- Store the currency in a separate column, if necessary. It's possible to use a foreign key to a currencies table, or the ENUM type.
- Use a non-approximated type:
  - DECIMAL is very convenient, as it allows one to store the number as-is. But calculations are potentially slower.
  - An integer type is faster for calculations. It is possible to store, for example, the amount of money multiplied by 100.

There is a small incompatibility that users should be aware about. `money` and `smallmoney` are accurate to about 4 decimal digits. This means that, if you use enough decimal digits, operations on these types may produce different results than the results they would produce on MariaDB types.

Bits

The BIT type is supported in MariaDB. Its maximum size is `BIT(64)`. The `BIT` type has a fixed length. If we insert a value which requires less bits than the ones that are allocated, zero-bits are padded on the left.

In MariaDB, binary values can be written in one of the following ways:

- `b'value'`
- `0value` where `value` is a sequence of 0 and 1 digits. Hexadecimal syntax can also be used. For more details, see Binary Literals and Hexadecimal Literals.

MariaDB and SQL Server have different sets of bitwise operators. See Bit Functions and Operators.

BOOLEAN Pseudo-Type

In SQL Server, it is common to use `bit` to represent boolean values. In MariaDB it is possible to do the same, but this is not a common practice.

A column can also be defined as BOOLEAN or `BOOL`, which is just a synonym for TINYINT. `TRUE` and `FALSE` keywords also exist, but they are synonyms for 1 and 0. To understand what this implies, see Boolean Literals.

In MariaDB `'True'` and `'False'` are always strings.

Date and Time

SQL Server Types	Range	Precision	Size (bytes)	MariaDB Types	Range	Size (bytes)	Precision	Notes
date	0001-01-01 - 9999-12-31	3	/	DATE	0001-01-01 - 9999-12-31	3	/	They cover the same range
datetime	1753-01-01 - 9999-12-31	8	0 to 3, rounded	DATETIME	001-01-01 - 9999-12-31	8	0 to 6	MariaDB values are not approximated, see below.
datetime2	001-01-01 - 9999-12-31	8	6 to 8	DATETIME	001-01-01 - 9999-12-31	8	0 to 6	MariaDB values are not approximated, see below.
smalldatetime				DATETIME				
datetimeoffset				DATETIME				
time				TIME				

You may also consider the following MariaDB types:

- TIMESTAMP has little to do with SQL Server's `timestamp`. In MariaDB it is the number of seconds elapsed since the beginning of 1970-01-01, with a decimal precision up to 6 digits (0 by default). The maximum allowed value is '2038-01-19 03:14:07'. Values are always stored in UTC. A TIMESTAMP column can optionally be automatically set to the current timestamp on insert, on update, or both. It is not meant to be a unique row identifier. Also, in MariaDB the range of TIMESTAMP values is
- YEAR is a 1-byte type representing years between 1901 and 2155, as well as 0000.

Zero Values

MariaDB allows a special value where all the parts of a date are zeroes: `'0000-00-00'`. This can be disallowed by setting sql_mode=NO_ZERO_DATE.

It is also possible to use values where only some date parts are zeroes, for example `'1994-01-00'` or `'1994-00-00'`. These values can be disallowed by setting sql_mode=NO_ZERO_IN_DATE. They are not affected by `NO_ZERO_DATE`.

Syntax

Several different date formats are understood. Typically used formats are `'YYYY-MM-DD'` and `YYYYMMDD`. Several separators are accepted.

The syntax defined in standard SQL and ODBC are understood - for example, `DATE '1994-01-01'` and `{d '1994-01-01'}`. Using these eliminates possible ambiguities in contexts where a temporal value could be interpreted as a string or as an integer.

See Date and Time Literals for the details.

Precision

For temporal types that include a day time, MariaDB allows a precision from 0 to 6 (microseconds), 0 being the default. The subsecond part is never approximated. It adds up to 3 bytes. See Data Type Storage Requirements for the details.

String and Binary

Binary Strings

SQL Server Types	Size (bytes)	MariaDB Types	Notes
binary	1 to 8000	VARBINARY or BLOB	See below for BLOB types
varbinary	1 to 8000	VARBINARY or BLOB	See below for BLOB types
image	2^31-1	VARBINARY or BLOB	See below for BLOB types

The `VARBINARY` type is similar to `VARCHAR`, but stores binary byte strings, just like SQL Server `binary` does.

For large binary strings, MariaDB has four `BLOB` types, with different sizes. See BLOB and TEXT Data Types for more information.

Character Strings

One important difference between SQL Server and MariaDB is that **in MariaDB character sets do not depend on types and collations**. Character sets can be set at database, table or column level. If this is not done, the default character sets applies, which is specified by the character_set_server system variable.

To create a MariaDB table that is identical to a SQL Server table, **it may be necessary to specify a character set for each string column**. However, in many cases using UTF-8 will work.

SQL Server Types	Size (bytes)	MariaDB Types	Size (bytes)	Character set
char	1 to 8000	CHAR	0 to 255	utf8mb4 (1, 4)
varchar	1 to 8000	VARCHAR	0 to 65,532 (2)	utf8mb4 (1)
text	2^31-1	TEXT	2^31-1	ucs2
nchar	2 to 8000	CHAR	0 to 255	utf16 or ucs2 (3, 4)
nvarchar	2 to 8000	VARCHAR	0 to 65,532 (2) (5)	utf16 or ucs2 (1) (3)
ntext	2^30 - 1	TEXT	2^31-1	ucs2

Notes:

1. If SQL Server uses a non-unicode collation, a subset of UTF-8 is used. So it is possible to use a smaller character set on MariaDB too.
2. InnoDB has a maximum row length of 65,535 bytes. TEXT columns do not contribute to the row size, because they are stored separately (except for the first 12 bytes).
3. In SQL Server, UTF-16 is used if data contains Supplementary Characters, otherwise UCS-2 is used. If not sure, use `utf16` in MariaDB.
4. In SQL Server, the value of `ANSI_PADDING` determines if `char` values should be padded with spaces to their maximum length. In MariaDB, this depends on the PAD_CHAR_TO_FULL_LENGTH sql_mode flag.
5. See JSON, below.

SQL Server Special Types

rowversion

MariaDB does not have the `rowversion` type.

If the only purpose is to check if a row has been modified since its last read, a TIMESTAMP column can be used instead. Its default value should be `ON UPDATE CURRENT_TIMESTAMP`. In this way, the timestamp will be updated whenever the column is modified.

A way to preserve much more information is to use a temporal table. Past versions of the row will be preserved.

sql_variant

MariaDB does not support the `sql_variant` type.

MariaDB is quite flexible about implicit and explicit type conversions. Therefore, for most cases storing the values as a string should be equivalent to using `sql_variant`.

Be aware that the maximum length of an `sql_variant` value is 8,000 bytes. In MariaDB, you may need to use `TINYBLOB`.

uniqueidentifier

While MariaDB does not support the `uniqueidentifier` type, the UUID type can typically be used for the same purpose.

`uniqueidentifier` columns contain 16-bit GUIDs. MariaDB UUID columns store UUIDv1 values (128 bits).

The UUID type was implemented in MariaDB 10.7. On older versions, you can generate unique values with the UUID() or UUID_SHORT() functions, and store them in `BIT(128)` or `BIT(64)` columns, respectively.

xml

MariaDB does not support the `xml` type.

XML data can be stored in string columns. MariaDB supports several XML functions.

JSON

With SQL Server, typically JSON documents are stored in `nvarchar` columns in a text form.

MariaDB has a JSON pseudo-type that maps to LONGTEXT. However, from MariaDB 10.5 the `JSON` pseudo-type also checks that the value is valid a JSON document.

MariaDB supports different JSON functions than SQL Server. MariaDB currently has more functions, and SQL Server syntax will not work. See JSON functions for more information.

MariaDB Specific Types

The following types are supported by MariaDB and don't have a direct equivalent in SQL Server. If you are migrating your database to MariaDB, you can consider using these types.

- INET6 - IPv6 addresses.
- INET4 - IPv4 addresses.

This page is licensed: CC BY-SA / Gnu FDL

Syntax Differences between MariaDB and SQL Server

This article contains a non-exhaustive list of syntax differences between MariaDB and SQL Server and is written for SQL Server users who are unfamiliar with MariaDB.

Compatibility Features

Some features are meant to improve syntax and semantics compatibility between MariaDB versions, between MariaDB and MySQL, and between MariaDB and other DBMSs. This section focuses on compatibility between MariaDB and SQL Server.

sql_mode and old_mode

SQL semantics and syntax, in MariaDB, are affected by the sql_mode variable. Its value is a comma-separated list of flags, and each of them, if specified, affects a different aspect of SQL syntax and semantics.

A particularly important flag for users familiar with SQL Server is MSSQL.

sql_mode can be changed locally, in which case it only affects the current session; or globally, in which case it will affect all new connections (but not the connections already established). sql_mode must be assigned a comma-separated list of flags.

A usage example:

```
# check the current global and local sql_mode values
SELECT @@global.sql_mode;
SELECT @@session.sql_mode;
# empty sql_mode for all users
SET GLOBAL sql_mode = '';
# add MSSQL flag to the sql_mode for the current session
SET SESSION sql_mode = CONCAT(sql_mode, ',MSSQL');
```

old_mode is very similar to sql_mode, but its purpose is to provide compatibility with older MariaDB versions. Its flags shouldn't affect compatibility with SQL Server (though it is theoretically possible that some of them do, as a side effect).

Executable Comments

MariaDB supports executable comments. These are designed to write generic queries that are only executed by MariaDB, and optionally only certain versions.

The following examples show how to insert SQL code that will be ignored by SQL Server but executed by MariaDB, or some of its versions.

- Executed by MariaDB and MySQL (see below):

```
SELECT * FROM tab /*! FORCE INDEX (idx_a) */ WHERE a = 1 OR b = 2;
```

- Executed by MariaDB only:

```
SELECT * /*M! , @in_transaction */ FROM tab;
```

- Executed by MariaDB starting from version 10.0.5:

```
DELETE FROM user WHERE id = 100 /*!M100005 RETURNING email */;
```

As explained in the Understanding MariaDB Architecture page, MariaDB was initially forked from MySQL. At that time, executable comments were already supported by MySQL. This is why the `/*! ... */` syntax is supported by both MariaDB and MySQL. But because MariaDB also supports specific syntax not supported by MySQL, it added the `/*M! ... */` syntax.

Generic Syntax

Here we discuss some differences between MariaDB and SQL Server syntax that may affect any user, as well as some hints to make queries compatible with a reasonable amount of work.

Delimiters

SQL Server uses two different terminators:

- The batch terminator is the `go` command. It tells Microsoft clients to send the text we typed to SQL Server.
- The query terminator is a semicolon (`;`) and it tells SQL Server where a query ends.

It is rarely necessary to use `;` in SQL Server. It is required for certain common table expressions, for example.

But the same doesn't apply to MariaDB. **Normally, with MariaDB, you only use `;`.**

However, MariaDB also has some situations where you want to use a `;` but you don't want the mariadb command-line client to send the query yet. This can be done in any situation, but it is particularly useful when creating stored routines or using BEGIN NOT ATOMIC.

The reason is better explained with an example:

```
CREATE PROCEDURE p()
BEGIN
    SELECT * FROM t1;
    SELECT * FROM t2;
END;
```

If we enter this procedure in this way in the `mariadb` client, as soon as we type the first `;` (after the first `SELECT`) and press enter, the statement will be sent. MariaDB will try to parse it and will return an error.

To avoid this, `mariadb` implements the DELIMITER statement. This client statement is never sent to MariaDB. Instead, the client uses it to find out when the typed query should be sent. Let's correct the above example:

```
DELIMITER ||

CREATE PROCEDURE p()
BEGIN
    SELECT * FROM t1;
    SELECT * FROM t2;
END;

DELIMITER ;
```

Names

In MariaDB, most names have a maximum length of 64 characters. When migrating an SQL Server database to MariaDB, check if some names exceed this limit (SQL Server maximum length is 128).

By default, MariaDB names are case-sensitive if the operating system has case-sensitive file names (Linux), and case-insensitive if the operating system is case-insensitive (Windows). SQL Server is case-insensitive by default on all operating systems.

When migrating a SQL Server database to MariaDB on Linux, to avoid problems, you may want to set the lower_case_table_names system variable to 1, making table names, database names, and aliases case-insensitive.

Names can be quoted inside backtick characters (```). This character can be used in names, in which case it should be doubled. By default, this is the only way to quote names.

To also enable the use of double quotes (`"`), modify sql_mode by adding the `ANSI_QUOTES` flag. This is the equivalent of setting QUOTED_IDENTIFIER ON in SQL Server.

To also enable the use of SQL Server style quotes (`[` and `]`), modify sql_mode by adding the `MSSQL` flag.

The case-sensitivity of stored procedures and functions is never a problem, as they are case-insensitive in SQL Server.

Quoting Strings

In SQL Server, by default, strings can only be quoted with single-quotes (`'`), and to use a double quote in a string, it should be doubled (`''`). This also works by default in MariaDB.

SQL Server also allows to use of double quotes (`"`) to quote strings. This works by default in MariaDB, but as mentioned before, it won't work if sql_mode contains the `ANSI_QUOTES` flag.

NULL

The default semantics of NULL in SQL Server and MariaDB are the same, by default.

However, SQL Server allows one to change it globally with SET ANSI_NULLS OFF, or at the database level with ALTER DATABASE.

There is no way to achieve exactly the same result in MariaDB. To perform NULL-safe comparisons in MariaDB, one should replace the = operator with the <=> operator.

Also, note that MariaDB doesn't support the `UNKNOWN` pseudo-value. An expression like `NULL OR 0` returns `NULL` in MariaDB.

LIKE

In MariaDB, LIKE expressions only have two characters with special meanings: `%` and `_`. These two characters have the same meanings they have in SQL Server.

The additional characters recognized by SQL Server (`[`, `]` and `^`) are part of regular expressions. MariaDB supports the REGEXP operator that supports the full regular expression syntax.

Data Definition Language

Here we discuss some DDL differences that database administrators will want to be aware of.

While this section is meant to highlight the most noticeable DDL differences between MariaDB and SQL Server, there are many others, both in the syntax and in the semantics. See the ALTER statement documentation.

Altering Tables Online

Altering tables online can be a problem, especially when the tables are big and we don't want to cause a disruption.

MariaDB offers the following solutions to help:

- The ALTER TABLE … ALGORITHM clause allows one to specify which algorithm should be used to run a certain operation. For example, `INPLACE` tells MariaDB not to create a table copy (perhaps because we don't have enough disk space), and `INSTANT` tells MariaDB to execute the operation instantaneously. Not all algorithms are supported for certain operations. If the algorithm we've chosen cannot be used, the ALTER TABLE statement will fail with an error.
- The ALTER TABLE … LOCK clause allows one to specify which lock type should be used. For example, `NONE` tells MariaDB to avoid any lock on the table and `SHARED` only allows one to acquire a share lock. If the operation requires a lock that is more strict than the one, we are requesting, the ALTER TABLE statement will fail with an error. Sometimes this happens because the `LOCK` level we want is not available for the specified `ALGORITHM`.

To find out which operations require a table copy and which lock levels are necessary, see InnoDB Online DDL Overview.

An `ALTER TABLE` can be queued because a long-running statement (even a `SELECT`) requires a metadata lock. Since this may cause trouble, sometimes we want the operation to simply fail if the wait is too long. This can be achieved with the WAIT and NOWAIT clauses, whose syntax is a bit different from SQL Server.

SQL Server `WITH ONLINE = ON` is equivalent to MariaDB `LOCK = NONE`. However, note that most ALTER TABLE statements support `ALGORITHM = INSTANT`, which is non-blocking and much faster (almost instantaneous, as the syntax suggests).

IF EXISTS, IF NOT EXISTS, OR REPLACE

Most DDL statements, including ALTER TABLE, support the following syntax:

- `DROP IF EXISTS`: A warning (not an error) is produced if the object does not exist.
- `OR REPLACE`: If the object exists, it is dropped and recreated; otherwise, it is created. This operation is atomic, so at no point in time does the object not exist.
- `CREATE IF NOT EXISTS`: If the object already exists, a warning (not an error) is produced. The object will not be replaced.

These statements are functionally similar (but less verbose) than SQL Server snippets similar to the following:

```
IF NOT EXISTS (
        SELECT name
            FROM sysobjects
            WHERE name = 'my_table' AND xtype = 'U'
    )
    CREATE TABLE my_table (
        ...
    )
go
```

Altering Columns

With SQL Server, the only syntax to alter a table column is `ALTER TABLE ... ALTER COLUMN`. MariaDB provides more ALTER TABLE commands to obtain the same result:

- CHANGE COLUMN allows one to perform any change by specifying a new column definition, including the name.
- MODIFY COLUMN allows any change, except renaming the column. This is a slightly simpler syntax that we can use when we don't want to change a column name.
- ALTER COLUMN allows one to change or drop the `DEFAULT` value.
- RENAME COLUMN allows one to only change the column name.

Using a more specific syntax is less error-prone. For example, by using `ALTER TABLE ... ALTER COLUMN`,we will not accidentally change the data type.

The word `COLUMN` is usually optional, except in the case of `RENAME COLUMN`.

SHOW Statements

MariaDB supports SHOW statements to quickly list all objects of a certain type (tables, views, triggers…). Most `SHOW` statements support a `LIKE` clause to filter data. For example, to list the tables in the current database whose name begins with 'wp_':

```
SHOW TABLES LIKE 'wp\_%';
```

This is the equivalent of this query, which would work on both MariaDB and SQL Server:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_NAME LIKE 'wp\_';
```

SHOW CREATE Statements

In general, for each `CREATE` statement, MariaDB also supports a `SHOW CREATE` statement. For example, there is a SHOW CREATE TABLE that returns the CREATE TABLE statement that can be used to recreate a table.

Though SQL Server has no way to show the DDL statement to recreate an object, `SHOW CREATE` statements are functionally similar to `sp_helptext()`.

Database Comments

MariaDB does not support extended properties. Instead, it supports a `COMMENT` clause for most CREATE and ALTER statements.

For example, to create and then change a table comment:

```
CREATE TABLE counter (
    c INT UNSIGNED AUTO_INCREMENT PRIMARY KEY
)
    COMMENT 'Monotonic counter'
;
ALTER TABLE counter COMMENT
    'Counter. It can contain many values, we only care about the max';
```

Comments can be seen with `SHOW CREATE` statements or by querying `information_schema` tables. For example:

```
SELECT TABLE_COMMENT
    FROM information_schema.TABLES
    WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'counter';
+-------------------------------------------------------------------+
| TABLE_COMMENT                                                     |
+-------------------------------------------------------------------+
| Counter. It can contain many values, we only care about the max |
+-------------------------------------------------------------------+
```

Error Handling

MariaDB SHOW ERRORS and SHOW WARNINGS statements can be used to show errors, or warnings and errors. This is convenient for clients, but stored procedures cannot work with the output of these commands.

Instead, inside stored procedures, you can:

- Use the GET DIAGNOSTICS command to assign error properties to variables. This is the equivalent of using SQL Server functions like `ERROR_NUMBER()` or `ERROR_STATE()`.
- Add a DECLARE HANDLER block to handle all errors, a class of errors, or a specific error. This is the equivalent of SQL Server `TRY ... CATCH`.
- An error or warning can be generated on purpose using SIGNAL. Inside a `DECLARE HANDLER` block, RESIGNAL can be used to issue the error again and interrupt the execution of the block. These are the equivalents of SQL Server `RAISERROR()`.

Administration

Administration and maintenance commands in MariaDB use a different syntax from SQL Server.

- OPTIMIZE TABLE rebuilds table data and indexes. It can be considered as the MariaDB equivalent of SQL Server's `ALTER INDEX REBUILD`. See Defragmenting InnoDB Tablespaces for more information. This statement is always locked. It supports WAIT and NOWAIT syntax,
- MariaDB has an ANALYZE TABLE command, which is equivalent to `UPDATE STATISTICS`.

BULK INSERT

MariaDB has no `BULK INSERT` statement. Instead, it supports:

- LOAD DATA INFILE to load data from files in CSV or similar formats;
- LOAD XML INFILE to load data from XML files.

See also How to Quickly Insert Data Into MariaDB.

MariaDB Authorization and Permissions for SQL Server Users

Understanding Accounts and Users

MariaDB authorizes access and check permissions on accounts, rather than users. Even if MariaDB supports standard SQL commands like CREATE USER and DROP USER, it is important to remember that it actually works with accounts.

An account is specified in the format `'user'@'host'`. The quotes are optional and allow one to include special characters, like dots. The host part can actually be a pattern, which follows the same syntax used in `LIKE` comparisons. Patterns are often convenient because they can match several hostnames.

Here are some examples.

Omitting the host part indicates an account that can access from any host. So the following statements are equivalent:

```
CREATE USER viviana;
CREATE USER viviana@'%';
```

However, such accounts may be unable to connect from localhost if an anonymous user `''@'%'` is present. See localhost and % for the details.

Accounts are not bound to a specific database. They are global. Once an account is created, it is possible to assign it permissions on any existing or non existing database.

The sql_mode system variable has a NO_AUTO_CREATE_USER flag. In recent MariaDB versions it is enabled by default. If it is not enabled, a GRANT statement specifying privileges for a non-existent account will automatically create that account.

For more information: Account Management SQL Commands.

Setting or Changing Passwords

Accounts with the same username can have different passwords.

By default, an account has no password. A password can be set, or changed, in the following way:

- By specifying it in CREATE USER.
- By the user, with SET PASSWORD.
- By root, with `SET PASSWORD` or ALTER USER.

With all these statements (`CREATE USER`, `ALTER USER`, `SET PASSWORD`) it is possible to specify the password in plain or as a hash:

```
-- specifying plain passwords:
CREATE USER tom@'%.example.com' IDENTIFIED BY 'plain secret';
ALTER USER tom@'%.example.com' IDENTIFIED BY 'plain secret';
SET PASSWORD = 'plain secret';
-- specifying hashes:
CREATE USER tom@'%.example.com' IDENTIFIED BY PASSWORD 'secret hash';
ALTER USER tom@'%.example.com' IDENTIFIED BY PASSWORD 'secret hash';
SET PASSWORD = PASSWORD('secret hash');
```

The PASSWORD() function uses the same algorithm used internally by MariaDB to generate hashes. Therefore it can be used to get a hash from a plain password. Note that this function should not be used by applications, as its output may depend on MariaDB version and configuration.

`SET PASSWORD` applies to the current account, by default. Superusers can change other accounts passwords in this way:

```
SET PASSWORD FOR tom@'%.example.com' = PASSWORD 'secret hash';
```

Passwords can have an expiry date, set by default_password_lifetime. To set a different date for a particular user:

```
CREATE USER 'tom'@'%.example.com' PASSWORD EXPIRE INTERVAL 365 DAY;
```

To set no expiry date for a particular user:

```
CREATE USER 'tom'@'%.example.com' PASSWORD EXPIRE NEVER;
```

For more details, see User Password Expiry.

It is also possible to lock an account with immediate effect:

```
CREATE USER 'tom'@'%.example.com' ACCOUNT LOCK;
```

See Account Locking for more details.

Authentication Plugins

MariaDB supports authentication plugins. These plugins implement user's login and authorization before they can use MariaDB.

Each user has one or more authentication plugins assigned. The default one is mysql_native_password. It is the traditional login using the username and password set in MariaDB, as described above.

On UNIX systems, root is also assigned the unix_socket plugin, which allows a user logged in the operating system to be recognized by MariaDB.

Windows users may be interested in the named pipe and GSSAPI plugins. GSSAPI also requires the use of a plugin on the client side.

A plugin can be assigned to a user with `CREATE USER`, `ALTER USER` or `GRANT`, using the `IDENTIFIED VIA` syntax. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA named_pipe;
```

TLS connections

A particular user can be required to use TLS connections. Additional requirements can be set:

- Having a valid X509 certificate.
- The certificate may be required to be issued by a particular authority.
- A particular certificate subject can be required.
- A particular certificate cipher suite can be required.

These requirements can be set with `CREATE USER`, `ALTER USER` or `GRANT`. For the syntax, see CREATE USER.

MariaDB can be bundled with several cryptography libraries, depending on its version. For more information about the libraries, see TLS and Cryptography Libraries Used by MariaDB.

For more information about secure connections, see Secure Connections Overview.

Permissions

Permissions can be granted to accounts. As mentioned before, the specified accounts can actually be patterns, and multiple accounts may match a pattern. For example, in this example we are creating three accounts, and we are assigning permissions to all of them:

```
CREATE USER 'tom'@'example.com';
CREATE USER 'tom'@'123.123.123.123;
CREATE USER 'tom'@'tomlaptop';
GRANT USAGE ON *.* TO tom@'%';
```

The following permission levels exist in MariaDB:

- Global privileges;

- Database privileges;
- Table privileges;
- Column privileges;
- Function and procedure privileges.

Note that database and schema are synonymous in MariaDB.

Permissions can be granted for non-existent objects that could exist in the future.

The list of supported privileges can be found in the GRANT page. Some highlights can be useful for SQL Server users:

- `USAGE` privilege has no effect. The `GRANT` command fails if we don't grant at least one privilege; but sometimes we want to run it for other purposes, for example to require a user to use TLS connections. In such cases, it is useful to grant `USAGE`.
- Normally we can obtain a list of all databases for which we have at least one permission. The `SHOW DATABASES` permission allows getting a list of all databases.
- There is no `SHOWPLAN` privilege in MariaDB. Instead, EXPLAIN requires the `SELECT` privilege for each accessed table and the `SHOW VIEW` privilege for each accessed view.
- The same permissions are needed to see a table structure (`SELECT`) or a view definition (`SHOW VIEW`).
- `REFERENCES` has no effect.

MariaDB does not support negative permissions (the `DENY` command).

Some differences concerning the SQL commands:

- In MariaDB `GRANT` and `REVOKE` statements can only assign/revoke permissions to one user at a time.
- While we can assign/revoke privileges at column level, we have to run a `GRANT` or `REVOKE` statement for each column. The `table (column_list)` syntax is not recognized by MariaDB.
- In MariaDB it is not needed (or possible) to specify a class type.

Roles

MariaDB supports roles. Permissions can be assigned to roles, and roles can be assigned to accounts.

An account may have zero or one default roles. A default role is a role that is automatically active for a user when they connect. To assign an account or remove a default role, these SQL statements can be used:

```
SET DEFAULT ROLE some_role FOR username@hostname;
SET DEFAULT ROLE NONE FOR username@hostname;
```

Normally a role is not a default role. If we assign a role in this way:

```
GRANT some_role TO username@hostname;
```

…the user will not have that role automatically enabled. They will have to enable it explicitly:

```
SET ROLE some_role;
```

MariaDB does not have predefined roles, like public.

For an introduction to roles, see Roles Overview.

This page is licensed: CC BY-SA / Gnu FDL

MariaDB Replication Overview for SQL Server Users

MariaDB supports the following types of replication:

- Asynchronous replication.
- Semi-synchronous replication.
- Galera Cluster.

MariaDB starting with 10.5.1

Note: in the snippets in this page, several SQL statements use the keyword `SLAVE`. This word is considered inappropriate by some persons or cultures, so from MariaDB 10.5 it is possible to use the `REPLICA` keyword, as a synonym.
Similar synonyms will be created in the future for status variables and system variables. See MDEV-18777 to track the status of these changes.

Asynchronous Replication

The original MariaDB replication system is asynchronous primary-replica replication.

A primary needs to have the binary log enabled. The primary logs all data changes in the binary log. Every *event* (a binary log entry) is sent to all the replicas.

For a high-level description of the binary log for SQL Server users, see Understanding MariaDB Architecture.

The events can be written in two formats: as an SQL statement (*statement-based replication*, or SBR), or as a binary representation of the change (*row-based replication*, or RBR). The former is generally slower, because the statement needs to be re-executed by the replicas. It is also less reliable, because some SQL statements are not deterministic, so they could produce different results on the replicas. On the other hand row-based replication could make the binary log much bigger, and require more network traffic. For this reason, DML statements are always logged in statement format.

For more details on replication formats, see binary log formats.

The replicas have an I/O thread that receives the binary log events and writes them to the relay log. These events are then read by the SQL thread. This thread could directly apply the changes to the local databases, and this was the only option before MariaDB 10.0.5. If parallel replication is enabled, the SQL thread hands the events to the worker thread, that apply them to the databases. The latter method is recommended for performance reasons.

When a replica cannot apply an event to the local data, the SQL thread stops. This happens, for example, if the event is a row deletion but that row doesn't exist on the replica. There can be several reasons for this, for example non-deterministic statements, or a user deleted the row in the replica. To reduce the risk, it is recommended to set read_only to 1 in the replicas.

SHOW SLAVE STATUS has columns named `Slave_SQL_State` and `Slave_IO_State` that show, respectively, if the SQL thread and the IO thread are running. If they are not, the column `Last_IO_Errno` and `Last_IO_Error` (for the IO thread) or `Last_SQL_Errno` and `Last_SQL_Error` (for the SQL thread) show what the problem is.

In a replication chain, every server must have a unique server_id.

For more information on replication, see standard replication.

Binary Log Coordinates, Relay Log Coordinates and GTID

The binary log coordinates provide a way to identify a certain data change made by a server. Coordinates consist of a file name and the position of the latest event, expressed as an integer. The last event coordinates can be seen with the SHOW MASTER STATUS columns `File` and `Position`. mariadb-dump includes them in a dump if the `--master-data` option is used.

A replica uses primary binary log coordinates to identify the last event it read. This can be seen with the SHOW SLAVE STATUS columns `Master_Log_File` and `Read_Master_Log_Pos`.

The columns `Relay_Master_Log_File` and `Exec_Master_Log_Pos` identify the primary event that corresponds to the last event applied by the SQL thread.

The replica relay log also has coordinates. The coordinates of the last applied event can be seen with the `SHOW SLAVE STATUS` columns `Relay_Log_File` and `Relay_Log_Pos`.

To easily find out how far the replica is lagging behind the primary, we can look at `Seconds_Behind_Master`.

Coordinates represented in this way have a problem: they are different on each server. Each server can use files with different (or the same) names, depending on its configuration. And files can be rotated at different times, including when a user runs FLUSH LOGS. By enabling the GTID (global transaction id) an event will have the same id on the primary and on all the replicas.

When GTID is enabled, `SHOW SLAVE STATUS` shows two GTIDs: `Gtid_IO_Pos` is the last event written into the relay log, and `Gtid_Slave_Pos` is the last event applied by the SQL thread. There is no need for a column identifying the same event in the primary, because the id is the same.

Provisioning a Replica

MariaDB does not have an equivalent to SQL Server's snapshot replication.

To setup a replica, it is necessary to manually provision it. It can be provisioned from the primary in this way:

- A backup from the primary must be restored on the new replica;
- The binary log coordinates at the moment of the backup should be set as replication coordinates in the replica, via CHANGE MASTER TO.

However, if there is at least one existing replica, it is better to use it to provision the new replica:

- A backup from the existing replica must be restored in the new replica;
- The backup should include the system tables. In this way it will not be necessary to set the correct coordinates manually.

For more information see Setting Up Replication and Setting up a Replica with mariadb-backup.

Replication and Permissions

A replica connects to a primary using its credentials. See CHANGE MASTER TO.

The appropriate account must be created in the primary, and it needs to have the `REPLICATION SLAVE` permission.

See Setting Up Replication for more information.

Parallel Replication and Group Commit

MariaDB uses group commit, which means that a group of events are physically written in the binary log altogether. This reduces the number of IOPS (input/output operations per second). Group commit cannot be disabled, but it can be tuned with variables like binlog_commit_wait_count and binlog_commit_wait_usec.

Replicas can apply the changes using multiple threads. This is known as parallel replication. Before MariaDB 10.0.5 only one thread was used to apply changes. Since a primary can use many threads to write data, mono-thread replication is a well-known bottleneck. Parallel replication is not enabled by default. To use it, set the slave_parallel_threads variable to a number greater than 1. If replication is running, the replica threads must be stopped in order to change this value:

```
STOP SLAVE SQL_THREAD;
SET GLOBAL slave_parallel_threads = 4;
START SLAVE SQL_THREAD;
```

There are different parallel replication styles available: in-order and out-of-order. The exact mode in use is determined by the slave_parallel_mode system variable. In parallel replication, the events are not replicated exactly in the same order as they occurred in the primary. But with an in-order replication mode the commit phase is always applied simultaneously. In this way data in the replica always reflect data as they have been in the primary at a certain point in time. Out-of-order replication is faster because there is less queuing, but it's not completely consistent with the primary. If two transactions modified different sets of rows in the primary, they could become visible in the replica in a different order.

`conservative` relies on primary group commit: events in different groups are executed in a parallel way.

`optimistic` does not try to find out which transaction can be executed in a parallel way - except for transactions that conflicted on the primary. Instead, it always tries to apply many events together, and rolls transactions back when there is a conflict.

`aggressive` is similar to optimistic, but it does not take into account which transactions conflicted in the primary.

`minimal` applies commits together, but all other events are applied in order.

Out-of-order replication cannot be enabled automatically by changing a variable in the replica. Instead, it must be enabled by the applications that run transactions in the primary. They can do this if the GTID is enabled. They can set different values for the gtid_domain_id variable in different transactions. This shifts a lot of responsibility to the application layer; however, if the application is aware of which transactions are not going to conflict and this information allows one to sensibly increase the parallelism, and using out-of-order replication can be a good idea.

Even if out-of-order replication is not normally used, it can be a good idea to use it for long running transactions or ALTER TABLEs, so they can be applied at the same time as normal operations that are not conflicting.

The impact of the number of threads and mode on performance can be partly seen with SHOW PROCESSLIST, which shows the state of all threads. This includes the replication worker threads, and shows if they are blocking each other.

Differences Between the Primary and the Replicas

As a general rule, we want the primary and the replicas to contain exactly the same data. In this way, no conflicts are possible. Conflicts are the most likely cause of replication outages.

To reduce the possible causes of conflicts, the following best practices are recommended:

- Users must not change data in the replica directly. Set read_only to 1. Note that this won't prevent root from making changes.
- Use the same table definitions in the primary and in the replica.
- Use `ROW` binary log format on the primary.

Another cause of inconsistencies include MariaDB bugs and failover in case the primary crashes.

An open source third party tool is available to check if the primary and a replica are consistent. It is called pt-table-checksum. Another tool, pt-table-sync, can be used to eliminate the differences. Both are part of Percona Toolkit. The advice is to run pt-table-checksum periodically, and use pt-table-sync if inconsistencies are found.

If a replication outage occurs because an inconsistency is found, sometimes we want to quickly bring the replica up again as quickly as possible, and solve the core problem later. If GTID is not used, a way to do this is to run SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1, which skips the problematic replication event.

If GTID is used, the gtid_slave_pos variable can be used instead. See the link for an explanation of how it works.

There are ways to have different data on the replicas. For example:

- Multi-source replication is possible. In this way, a replica will replicate data from multiple primaries. This feature is described below.

- Replication filters are supported. This allows one to exclude or include in replication specific tables, entire databases, or tables whose name matches a certain pattern. This allows one to avoid replicating data that is present in the primary but can always be rebuilt.
- Differences in table definitions are also possible. For example, a replica could have more columns or less columns compared to the primary. In this way we can avoid replicating columns whose values can be rebuilt. Or we can add columns for analytics purposes, without having them in the primary. Be sure to understand the limitations and risks of this technique.

Delayed Replication

MariaDB supports delayed replication. This is the equivalent of setting a `pollinginterval` in SQL Server.

To delay replication in a MariaDB replica, use CHANGE MASTER TO to specify a delay in seconds.

For more information, see Delayed Replication.

Multi-Source Replication

Multi-source replication is an equivalent to peer-to-peer replication, available in SQL Server Enterprise Edition.

A MariaDB replica can replicate from any number of primaries. It is very important that different primaries don't have the same tables. Otherwise there could be conflicts between data changes made on different primaries, and this will result in a replication outage.

In multi-source replication different channels exist, one for each primary.

This changed the way SQL replication statements work. SHOW PROCESSLIST returns a different row for each channel. Several statements, like CHANGE MASTER TO, START SLAVE or STOP SLAVE. accept a parameter which specifies which replication channel they should affect. For example, to stop a channel called `wp1`:

```
STOP SLAVE "wp1";
```

Furthermore, variables that affect parallel replication can be prefixed with a channel name. This allow one to only use parallel replication for certain channels, or to tune it differently for each channel. For example, to enable parallel replication on a channel called `wp1`:

```
SET GLOBAL wp1.slave_parallel_threads = 4;
```

Dual Primary

It is possible to configure two servers in a way that each of them acts as a primary for the other server.

In this way, data could theoretically be inserted into any of these servers, and will then be replicated to the other server. However, in such a configuration conflicts are very likely. So it is impractical to use this technique to scale writes.

A dual primary (or primary-primary) configuration however can be useful for failover. In this case we talk about an *active primary* that receives reads and writes from the clients, and a *passive primary* that is not used until the active primary crashes.

Several problems should be considered in this scenario:

- If the active primary crashes, it is very possible that the passive primary did not receive all events yet, because replication is asynchronous. If the primary data are lost (for example because the disk is damaged), some data are also lost.
- If data is not lost, when we bring the primary up again, the latest events will be replicated by the other server. There could be conflicts that will break replication.

- When is the active primary considered down? Even if a server cannot reach it, the active primary could be running and it could be able to communicate with the passive primary. Switching the clients to the passive primary could lead to unnecessary problems. It is a good idea to always check `SHOW SLAVE STATUS` to be sure that the two primary are not communicating.
- If we want to have more replicas, we should attach some of them to the active primary, and some of them to the passive primary. The reason is that when a server crashes, its replicas stop receiving any data. Failover is still possible, but it's better to have some servers that will not need any failover.

A safe primary-primary configuration where both servers accept writes, however, is possible. This is the case is data never conflicts. For example, the two servers could accept writes on different databases. We will have to decide what should happens in case of a server crash:

- Writes can be stopped until the server is up again. Reads can be sent to the other server, but keep in mind that the most recently written data could be missing.
- Both writes and reads can failover to the other server. All the problems mentioned above may apply to this situation.

See Sveta Smirnova's slides at MariaDB Day 2020: "How Safe is Asynchronous Master-Master Setup?".

Semi-Synchronous Replication

Semi-synchronous replication was initially implemented as a plugin, in MySQL. Two different plugins needed to be used, one on the primary and the other on the replicas. Starting from MariaDB 10.3.3 it is built-in, which improved its performance.

The problem with standard replication is that there is no guarantee that it will not lag, even by long amounts of time. Semi-synchronous replication reduces this problem, at the cost of reducing the speed of the primary.

In semi-synchronous replication, when a transaction is committed on the primary, the primary does not immediately return control to the client. Instead, it sends the event to the replicas. After one replica reported that the commit was executed with success, the primary reports success to the client.

Semi-synchronous replication is useful for failover, therefore a dual primary setup is not needed in this case. If the primary crashes, the most up-to-date replica can be promoted to primary without losing any data.

Enabling Semi-Synchronous Replication

Semi-synchronous replication can be enabled at runtime in this way on the primary:

```
SET GLOBAL rpl_semi_sync_master_enabled = ON;
```

Semi-synchronous replication is not used until it has been enabled on the replicas also. If the replicas are already replicating, the io_thread needs to be stopped and restarted. This can be done as follows:

```
SET GLOBAL rpl_semi_sync_slave_enabled = ON;
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

Tuning the Wait Point and the Primary Timeout

The most important aspects to tune are the wait point and the primary timeout.

When the binary log is enabled, transactions must be committed both in the storage engine (usually InnoDB) and in the binary log. Semi-synchronous replication requires that the transaction is also acknowledged by at least one replica before the primary can report success to the client.

The wait point determines at which point the primary must stop and wait for a confirmation from a replica. This is an important decision from disaster recovery standpoint, in case the primary crashes when a transaction is not fully

committed. The rpl_semi_sync_master_wait_point is used to set the wait point, Its allowed values are:

- `AFTER_SYNC`: After committing the transaction in the binary log, but before committing it to the storage engine. After a crash, a transaction may be present in the binary log even if it was not committed.
- `AFTER_COMMIT`. After committing a transaction both in the binary log and in the storage engine. In case of a crash, a transaction could possibly be committed in the primary but not replicated in the slaves. This is the default.

Primary timeout is meant to avoid that a primary remains stuck for a long time, or virtually forever, because no replica acknowledges a transaction. If primary timeout is reached, the primary switches to asynchronous replication. Before doing that, the primary writes an error in the error log and increments the Rpl_semi_sync_master_no_times status variable.

The timeout is set via the rpl_semi_sync_master_timeout variable.

Galera Cluster

Galera is a technology that implements virtually synchronous, primary-primary replication for a cluster of MariaDB servers.

Raft and the Primary Cluster

Nodes of the cluster communicate using the Raft protocol. In case the cluster is partitioned or some nodes crash, a cluster knows that it's still the *primary cluster* if it has the *quorum*: half of the nodes + 1. Only the primary cluster accepts reads and writes.

For this reason a cluster should consist of an odd number of nodes. Imagine for example that a cluster consists of two nodes: if one of them crashes of the connection between them is interrupted, there will be no primary cluster.

Transaction Certification

A transaction can be executed against any node. The node will use a 2-phase commit. After running the transaction locally, the node will ask other nodes to *certify* it. This means that other nodes will receive it, and will try to apply it, and will report success or a failure. The node that received the transaction will not wait for an answer from all the nodes. Once it succeeded on more than half of the nodes (the quorum) the node will run the final commit and data becomes visible.

It is desirable to write data on only one node (unless it fails), or write different databases on different nodes. This will minimize the risk of conflicts.

Galera Cache and SST

Data changes applied are recorded for some time in the *Galera cache*. This is an on-disk cache, written in a circularly written file.

The size of Galera cache can be tuned using the wsrep_provider_options system variable, which contains many flags. We need to tune gcache.size. To tune it, add a line similar to the following to a configuration file:

```
wsrep_provider_options = 'gcache.size=2G';
```

If a single transaction is bigger than half of the Galera cache, it needs to be written in a separate file, as *on-demand pages*. On-demand pages are regularly replaced. Whether a new page replaces an old one depends on another wsrep_provider_options flag: `wsrep_provider_options#gcachekeep_pages_size|gcache.keep_pages_size`, which limits the total size of on-demand pages.

When a node is restarted (after a crash or for maintenance reasons), it will need to receive all the changes that were written by other nodes since the moment it was unreachable. A node is therefore chosen as a donor, possibly using

the gcssync_donor wsrep_provider_options flag.

If possible, the donor will send all the recent changes, reading them from the Galera cache and on-demand pages. However, sometimes the Galera cache is not big enough to contain all the needed changes, or the on-demand pages have been overwritten because `gcache.keep_pages_size` is not big enough. In these cases, a State Snapshot Transfer (SST) needs to be sent. This means that the donor will send the whole dataset to the restarted node. Most commonly, this happens using the mariadb-backup method.

Flow Control

While transaction certification is synchronous, certified transactions are applied locally in asynchronous fashion. However, a node should never lag too much behind others. To avoid that, a node may occasionally trigger a mechanism called *flow control* to ask other nodes to stop replication until its situation improves. Several wsrep_provider_options flags affect flow control.

gcs.fc_master_slave should normally be set to 1 if all writes are sent to a single node.

gcs.fc_limit is tuned automatically, unless gcs.fc_master_slave is set to 0. The *receive queue* (the transactions received and not yet applied) should not exceed this limit. When this happens, flow control is triggered by the node to pause other node's replication.

Once flow control is activated, gcs.fc_factor determines when it is released. It is a number from 0 to 1, and it represents a fraction. When the receive queue is below this fraction, the flow control is released.

Flow control and the receive queue can and should be monitored. The most useful metrics are:

- wsrep_flow_control_paused indicates how many times the replication has been paused as requested by other nodes, since the last `FLUSH STATUS`.
- wsrep_flow_control_sent indicates how many times this node requested other nodes to pause replication.
- wsrep_local_recv_queue is the size of the receive queue.

Configuration

Galera is implemented as a plugin. Starting from version 10.1, MariaDB comes with Galera pre-installed, but not in use by default. To enable it one has to set the wsrep_on system variable.

Like asynchronous replication, Galera uses the binary log. It also requires that data changes are logged in the `ROW` format.

For other required settings, see Mandatory Options.

Galera Limitations

Galera is not suitable for all databases and workloads.

- Galera only replicates InnoDB tables. Other storage engines should not be used.
- For performance reasons, it is highly desirable that all tables have a primary key.
- Long transactions will damage performance.
- Some applications use an integer AUTO_INCREMENT primary key. In case of failover from a crashed node to another, Galera does not guarantee that `AUTO_INCREMENT` follows a chronological order. Therere, applications should use TIMESTAMP columns for chronological order instead.

MariaDB Transactions and Isolation Levels for SQL Server Users

This page explains how transactions work in MariaDB, and highlights the main differences between MariaDB and SQL Server transactions.

Note that XA transactions are handled in a completely different way and are not covered in this page. See XA Transactions.

Missing Features

These SQL Server features are not available in MariaDB:

- Autonomous transactions;
- Distributed transactions.

Transactions, Storage Engines and the Binary Log

In MariaDB, transactions are optionally implemented by storage engines. The default storage engine, InnoDB, fully supports transactions. Another transactional storage engine is MyRocks. Most storage engines are not transactional, therefore they should not considered general purpose engines.

Most of the information in this page refers to generic MariaDB server behaviors or InnoDB. For MyRocks please check the proper documentation section.

Writing into a non-transactional table in a transaction can still be useful. The reason is that a metadata lock is acquired on the table for the duration of the transaction, so that ALTER TABLEs are queued.

It is possible to write into transactional and non-transactional tables within a single transaction. It is important to remember that non-transactional engines will have the following limitations:

- In case of rollback, changes to non-transactional engines won't be undone. We will receive a warning `1196` which reminds us of this.
- Data in transactional tables cannot be changed by other connections in the middle of a transaction, but data in non-transactional tables can.
- In case of a crash, committed data written into a transactional table can always be recovered, but this is not necessarily true for non-transactional tables.

If the binary log is enabled, writing into different transactional storage engines in a single transaction, or writing into transactional and non-transactional engines inside the same transaction, implies some extra work for MariaDB. It needs to perform a two-phase commit to be sure that changes to different tables are logged in the correct order. This affects the performance.

Transaction Syntax

The first read or write to an InnoDB table starts a transaction. No data access is possible outside a transaction.

By default autocommit is on, which means that the transaction is committed automatically after each SQL statement. We can disable it, and manually commit transactions:

```
SET SESSION autocommit = 0;
SELECT ... ;
DELETE ... ;
COMMIT;
```

Whether autocommit is enabled or not, we can start transactions explicitly, and they will not be automatically committed:

```
START TRANSACTION;
SELECT ... ;
DELETE ... ;
COMMIT;
```

`BEGIN` can also be used to start a transaction, but does not work in stored procedures.

Read-only transactions are also available using `START TRANSACTION READ ONLY`. This is a small performance optimization. MariaDB will issue an error when trying to write data in the middle of a read-only transaction.

Only DML statements are transactional and can be rolled back. This may change in a future version, see MDEV-17567 - Atomic DDL and MDEV-4259 - transactional DDL.

Changing autocommit and explicitly starting a transaction will implicitly commit the active transaction, if any. DDL statements, and several other statements, implicitly commit the active transaction. See SQL statements That Cause an Implicit Commit for the complete list of these statements.

A rollback can also be triggered implicitly, when certain errors occur.

You can experiment with transactions to check in which cases they implicitly commit or rollback. The in_transaction system variable can help: it is set to 1 when a transaction is in progress, or 0 when no transaction is in progress.

This section only covers the basic syntax for transactions. Much more options are available. For more information, see Transactions.

Constraint Checking

MariaDB supports the following constraints:

- Primary keys
- UNIQUE
- CHECK
- Foreign keys

In some databases, constraints can temporarily be violated during a transaction, and their enforcement can be deferred to the commit time. SQL Server does not support this, and always validates data against constraints at the end of each statement.

MariaDB does something different: it always checks constraints after each row change. There are cases this policy makes some statements fail with an error, even if those statements would work on SQL Server.

For example, suppose you have an `id` column that is the primary key, and you need to increase its value for some reason:

```
SELECT id FROM customer;
```

```
+----+
| id |
+----+
|  1 |
|  2 |
|  3 |
|  4 |
|  5 |
+----+
```

```
UPDATE customer SET id = id + 1;
```

```
ERROR 1062 (23000): Duplicate entry '2' for key 'PRIMARY'
```

The reason why this happens is that, as the first thing, MariaDB tries to change 1 to 2, but a value of 2 is already present in the primary key.

A solution is to use this non-standard syntax:

```
UPDATE customer SET id = id + 1 ORDER BY id DESC;
Query OK, 5 rows affected (0.00 sec)
Rows matched: 5  Changed: 5  Warnings: 0
```

Changing the ids in reversed order won't duplicate any value.

Similar problems can happen with `CHECK` constraints and foreign keys. To solve them, we can use a different approach:

```
SET SESSION check_constraint_checks = 0;
-- run some queries
-- that temporarily violate a CHECK clause
SET SESSION check_constraint_checks = 1;

SET SESSION foreign_key_checks = 0;
-- run some queries
-- that temporarily violate a foreign key
SET SESSION foreign_key_checks = 1;
```

The last solutions temporarily disable `CHECK` constraints and foreign keys. Note that, while this may solve practical problems, it is dangerous because:

- This doesn't disable a single `CHECK` or foreign key, but also others, that you don't expect to violate.
- This doesn't defer the constraint checks, but it simply disables them for a while. This means that, if you insert some invalid values, they will not be detected.

See check_constraint_checks and foreign_key_checks system variables.

Isolation Levels and Locks

For more information about MariaDB isolation levels see SET TRANSACTION.

Locking Reads

In MariaDB, the locks acquired by a read do not depend on the isolation level (with one exception noted below).

As a general rule:

- Plain SELECTs are not locking, they acquire snapshots instead.
- To force a read to acquire a shared lock, use SELECT … LOCK IN SHARED MODE.
- To force a read to acquire an exclusive lock, use SELECT … FOR UPDATE.

Changing the Isolation Level

The default, the isolation level in MariaDB is `REPEATABLE READ`. This can be changed with the tx_isolation system variable.

Applications developed for SQL Server and later ported to MariaDB may run with `READ COMMITTED` without problems. Using a stricter level would reduce scalability. To use `READ COMMITTED` by default, add the following line to the MariaDB configuration file:

```
tx_isolation = 'READ COMMITTED'
```

It is also possible to change the default isolation level for the current session:

```
SET SESSION tx_isolation = 'read-committed';
```

Or just for one transaction, by issuing the following statement before starting a transaction:

```
SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
```

How Isolation Levels are Implemented in MariaDB

MariaDB supports the following isolation levels:

- `READ UNCOMMITTED`
- `READ COMMITTED`
- `REPEATABLE READ`
- `SERIALIZABLE`

MariaDB isolation levels differ from SQL Server in the following ways:

- `REPEATABLE READ` does not acquire share locks on all read rows, nor a range lock on the missing values that match a `WHERE` clause.
- It is not possible to change the isolation level in the middle of a transaction.
- `SNAPSHOT` isolation level is not supported. Instead, you can use `START TRANSACTION WITH CONSISTENT SNAPSHOT` to acquire a snapshot at the beginning of the transaction. This is compatible with all isolation levels.

Here is an example of `WITH CONSISTENT SNAPSHOT` usage:

```
-- session 1
SELECT * FROM t1;
```

```
+----+
| id |
+----+
|  1 |
+----+
```

```
SELECT * FROM t2;
```

```
+----+
| id |
+----+
|  1 |
+----+
```

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

```
-- session 2
INSERT INTO t1 VALUES (2);
```

```
-- session 1
SELECT * FROM t1;
```

```
+----+
| id |
+----+
|  1 |
+----+
```

```
-- session 2
INSERT INTO t2 VALUES (2);
```

```
-- session 1
SELECT * FROM t2;
```

```
+----+
| id |
+----+
|  1 |
+----+
```

As you can see, session 1 uses `WITH CONSISTENT SNAPSHOT`, thus it sees all tables as they were when the transaction begun.

Avoiding Lock Waits

When we try to read or modify a row that is exclusive-locked by another transaction, our transaction is queued until that lock is released. There could be more queued transactions waiting to acquire the same lock, in which case we will wait even more.

There is a timeout for such waits, defined by the innodb_lock_wait_timeout variable. If it is set to 0, statements that encounter a row lock will fail immediately. When the timeout is exceeded, MariaDB produces the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

It is important to note that this variable has two limitations (by design):

- It only affects transactional statements, not statements like `ALTER TABLE` or `TRUNCATE TABLE`.
- It only concerns row locks. It does not put a timeout on metadata locks, or table locks acquired - for example - with the LOCK TABLES statement.

Note however that lock_wait_timeout can be used for metadata locks.

There is a special syntax that can be used with `SELECT` and some non-transactional statements including `ALTER TABLE`: the WAIT and NOWAIT clauses. This syntax puts a timeout in seconds for all lock types, including row locks, table locks, and metadata locks. For example:

```
Session 1:
START TRANSACTION;
-- let's acquire a metadata lock
SELECT id FROM t WHERE 0;

Session 2:
DROP TABLE t WAIT 0;
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

InnoDB Transactions

InnoDB Lock Types

InnoDB locks are classified based on what exactly they lock, and which operations they lock.

The first classification is the following:

- Record Locks lock a row or, more precisely, an index entry.
- Gap Locks lock an interval between two index entries. Note that indexes have virtual values of -Infinum and Infinum, so a gap lock can cover the gap before the first or after the last index entry.
- Next-Key Locks lock an index entry and the gap between it and the next entry. They're a combination of record locks and gap locks.
- Insert Intention Locks are gap locks acquired before inserting a new row.

Lock modes are the following:

- Exclusive Locks (X) are generally acquired on writes, e.g. immediately before deleting a row. Only one exclusive lock can be acquired on a resource simultaneously.
- Shared Locks (S) can be acquired on reads. Multiple shared locks can be acquired at the same time (because the rows are not supposed to change when shared-locked) but are incompatible with exclusive locks.
- Intention locks (IS, XS) are acquired when it is not possible to acquire an exclusive lock or a shared lock. When a lock on a row or gap is released, the oldest intention lock on that resource (if any) is converted to an X or S lock.

For more information see InnoDB Lock Modes.

Information Schema

Querying the information_schema is the best way to see which transactions have acquired some locks and which transactions are waiting for some locks to be released.

In particular, check the following tables:

- INNODB_LOCKS: requests for locks not yet fulfilled, or that are blocking another transaction.
- INNODB_LOCK_WAITS: queued requests to acquire a lock.
- INNODB_TRX: information about all currently executing InnoDB transactions, including SQL queries that are running.

Here is an example of their usage.

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT l.*, t.*
    FROM information_schema.INNODB_LOCKS l
    JOIN information_schema.INNODB_TRX t
        ON l.lock_trx_id = t.trx_id
    WHERE trx_state = 'LOCK WAIT' \G
```

```
*************************** 1. row ***************************
                   lock_id: 840:40:3:2
               lock_trx_id: 840
                 lock_mode: X
                 lock_type: RECORD
                lock_table: `test`.`t`
                lock_index: PRIMARY
                lock_space: 40
                 lock_page: 3
                  lock_rec: 2
                 lock_data: 10
                    trx_id: 840
                 trx_state: LOCK WAIT
               trx_started: 2019-12-23 18:43:46
     trx_requested_lock_id: 840:40:3:2
          trx_wait_started: 2019-12-23 18:43:46
                trx_weight: 2
       trx_mysql_thread_id: 46
                 trx_query: DELETE FROM t WHERE id = 10
       trx_operation_state: starting index read
         trx_tables_in_use: 1
         trx_tables_locked: 1
          trx_lock_structs: 2
     trx_lock_memory_bytes: 1136
           trx_rows_locked: 1
         trx_rows_modified: 0
   trx_concurrency_tickets: 0
       trx_isolation_level: REPEATABLE READ
         trx_unique_checks: 1
    trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
          trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

Deadlocks

InnoDB detects deadlocks automatically. Since this consumes CPU time, some users prefer to disable this feature by setting the innodb_deadlock_detect variable to 0. If this is done, locked transactions will wait until the they exceed the innodb_lock_wait_timeout. Therefore it is important to set innodb_lock_wait_timeout to a very low value, like 1.

When InnoDB detects a deadlock, it kills the transaction that modified the least amount of data. The client will receive the following error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

The latest detected deadlock, and the killed transaction, can be viewed in the output of SHOW ENGINE InnoDB STATUS. Here's an example:

```
------------------------
LATEST DETECTED DEADLOCK
------------------------
2019-12-23 18:55:18 0x7f51045e3700
*** (1) TRANSACTION:

3 lock struct(s), heap size 1136, 2 row lock(s), undo log entries 1
MySQL thread id 39, OS thread handle 139985942361856, query id 840 localhost root Updating
delete from t where id = 11
*** (2) HOLDS THE LOCK(S):
RECORD LOCKS space id 40 page no 3 n bits 80 index PRIMARY of table `test`.`t` trx id 846 lock_mode X
locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 32
 0: len 4; hex 8000000a; asc     ;;
 1: len 6; hex 00000000034e; asc      N;;
 2: len 7; hex 760000019c0495; asc v      ;;

*** (2) WAITING FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 40 page no 3 n bits 80 index PRIMARY of table `test`.`t` trx id 846 lock_mode X
locks rec but not gap waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 32
 0: len 4; hex 8000000b; asc     ;;
 1: len 6; hex 00000000034f; asc      O;;
 2: len 7; hex 770000019d031d; asc w      ;;

*** WE ROLL BACK TRANSACTION (2)
```

The latest detected deadlock never disappears from the output of `SHOW ENGINE InnoDB STATUS`. If you cannot see any, MariaDB hasn't detected any InnoDB deadlocks since the last restart.

Another way to monitor deadlocks is to set innodb_print_all_deadlocks to 1 (0 is the default). InnoDB will log all detected deadlocks into the error log.

Moving Data Between SQL Server and MariaDB

There are several ways to move data between SQL Server and MariaDB. Here we will discuss them and we will highlight some caveats.

Moving Data Definition from SQL Server to MariaDB

To copy SQL Server data structures to MariaDB, one has to:

1. Generate a CSV file from SQL Server data.
2. Modify the syntax so that it works in MariaDB.
3. Run the file in MariaDB.

Variables That Affect DDL Statements

DDL statements are affected by some server system variables.

sql_mode determines the behavior of some SQL statements and expressions, including how strict error checking is, and some details regarding the syntax. Objects like stored procedures, stored functions triggers and views, are always executed with the sql_mode that was in effect during their creation. sql_mode='MSSQL' can be used to have MariaDB behaving as close to SQL Server as possible.

innodb_strict_mode enables the so-called InnoDB strict mode. Normally some errors in the CREATE TABLE options are ignored. When InnoDB strict mode is enabled, the creation of InnoDB tables will fail with an error when certain mistakes are made.

updatable_views_with_limit determines whether view updates can be made with an UPDATE or DELETE statement with a `LIMIT` clause if the view does not contain all primary or not null unique key columns from the underlying table.

Dumps and sys.sql_modules

SQL Server Management Studio allows one to create a working SQL script to recreate a database - something that MariaDB users refer to as a *dump*. Several options allow fine-tuning the generated syntax. It could be necessary to adjust some of these options to make the output compatible with MariaDB. It is possible to export schemas, data or both. One can create a single global file, or one file for each exported object. Normally, producing a single file is more practical.

Alternatively, the sp_helptext() procedure returns information about how to recreate a certain object. Similar information is also present in the sql_modules table (`definition` column), in the `sys` schema. Such information, however, is not a ready-to-use set of SQL statements.

Remember however that MariaDB does not support schemas. An SQL Server schema is approximately a MariaDB database.

To execute a dump, we can pass the file to mariadb, the MariaDB command-line client.

Provided that a dump file contains syntax that is valid in MariaDB, it can be executed in this way:

```
mariadb --show-warnings < dump.sql
```

`--show-warnings` tells MariaDB to output any warnings produced by the statements contained in the dump. Without this option, warnings will not appear on screen. Warnings don't stop the dump execution.

Errors will appear on screen. Errors will stop the dump execution, unless the `--force` option (or just `-f`) is specified.

For other `mariadb` options, see mariadb Command-line Client Options.

Another way to achieve the same purpose is to start the `mariadb` client in interactive mode first, and then run the `source` command. For example:

```
root@d5a54a082d1b:/# mariadb -uroot -psecret
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.4.7-MariaDB-1:10.4.7+maria~bionic mariadb.org binary distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> \W
Show warnings enabled.
MariaDB [(none)]> source dump.sql
```

In this case, to show warnings we used the `\W` command, where "w" is uppercase. To hide warnings (which is the default), we can use `\w` (lowercase).

For other `mariadb` commands, see mariadb Commands.

CSV Data

If the table structures are already in MariaDB, we need only to import table data. While this can still be done as explained above, it may be more practical to export CSV files from SQL Server and import them into MariaDB.

SQL Server Management Studio and several other Microsoft tools allow one to export CSV files.

MariaDB allows importing CSV files with the LOAD DATA INFILE statement, which is essentially the MariaDB equivalent of `BULK INSERT`.

It can happen that we don't want to import the whole data, but some filtered or transformed version of it. In that case, we may prefer to use the CONNECT storage engine to access CSV files and query them. The results of a query can be inserted into a table using INSERT SELECT.

Moving Data from MariaDB to SQL Server

There are several ways to move data from MariaDB to SQL Server:

- If the tables don't exist at all in SQL Server, we need to generate a dump first. The dump can include data or not.
- If the tables are already in SQL Server, we can use CSV files instead of dumps to move the rows. CSV files are the most concise format to move data between different technologies.
- With the tables already in SQL Server, another way to move data is to insert the rows into CONNECT tables that "point" to remote SQL Server tables.

Using a Dump (Structure)

mariadb-dump can be used to generate dumps of all databases, a specified database, or a set of tables. It is even possible to only dump a set of rows by specifying the `WHERE` clause.

By specifying the `--no-data` option we can dump the table structures without data.

`--compatible=mssql` will produce an output that should be usable in SQL Server.

Using a Dump (Data)

mariadb-dump by default produces an output with both data and structure.

`--no-create-info` can be used to skip the CREATE TABLE statements.

`--compatible=mssql` will produce an output that should be usable in SQL Server.

`--single-transaction` should be specified to select the source data in a single transaction, so that a consistent dump is produced.

`--quick` speeds up the dump process when dumping big tables.

Using a CSV File

CSV files can also be used to export data to SQL Server. There are several ways to produce CSV files from MariaDB:

- The SELECT INTO OUTFILE statement.
- The CONNECT storage engine, with the CSV table type.
- The CSV storage engine (note that it doesn't support `NULL` and indexes).

Using CONNECT Tables

The CONNECT storage engine allows one to access external data, in many forms:

- Data files (CSV, JSON, XML, HTML and more).
- Remote databases, using the ODBC or JDBC standards, or MariaDB/MySQL native protocol.
- Some special data sources.

`CONNECT` was mentioned previously because it could allow one to read a CSV file and query it in SQL, filtering and transforming the data that we want to move into regular MariaDB tables.

However, `CONNECT` can also access remote SQL Server tables. We can read data from it, or even write data.

To enable `CONNECT` to work with SQL Server, we need to fulfill these requirements:

- Install the ODBC driver, downloadable form Microsoft website. The driver is also available for Linux and MacOS.
- Install unixODBC.
- Install CONNECT (unless it is already installed).

Here is an example of a `CONNECT` table that points to a SQL Server table:

```
CREATE TABLE city (
    id INT PRIMARY KEY,
    city_name VARCHAR(100),
    province_id INT NOT NULL
)
    ENGINE=CONNECT,
    TABLE_TYPE=ODBC,
    TABNAME='city'
    CONNECTION='Driver=SQL Server Native Client 13.0;Server=sql-server-
hostname;Database=world;UID=mariadb_connect;PWD=secret';
```

The key points here are:

- `ENGINE=CONNECT` tells MariaDB that we want to create a `CONNECT` table.
- `TABLE_TYPE` must be 'ODBC', so `CONNECT` knows what type of data source it has to use.
- `CONNECTION` is the connection string to use, including server address, username and password.
- `TABNAME` tells `CONNECT` what the remote table is called. The local name could be different.

`CONNECT` is able to query SQL Server to find out the remote table structure. We can use this feature to avoid specifying the column names and types:

```
CREATE TABLE city
    ENGINE=CONNECT,
    TABLE_TYPE=ODBC,
    TABNAME='city'
    CONNECTION='Driver=SQL Server Native Client 13.0;Server=sql-server-
hostname;Database=world;UID=mariadb_connect;PWD=secret';
```

However, we may prefer to manually specify the MariaDB types, sizes and character sets to use.

Linked Server

Instead of using MariaDB `CONNECT`, it is possible to use SQL Server Linked Server functionality. This will allow one to read data from a remote MariaDB database and copy it into local SQL Server tables. However, note that `CONNECT` allows more control on types and character sets mapping.

Refer to Linked Servers section in Microsoft documentation.

Repairing MariaDB Tables for SQL Server Users

Repairing tables in MariaDB is not similar to repairing tables in SQL Server.

The first thing to understand is that every MariaDB table is handled by a storage engine. Storage engines are plugins that know how to physically read and write a table, so each storage engine allows one to repair tables in different ways. The default storage engine is InnoDB.

MariaDB provides specific SQL statements to deal with corrupted tables:

- CHECK TABLE checks if a table is corrupted;
- REPAIR TABLE repairs a table if it is corrupted.

As a general rule, there is no reason why a table that is corrupted on a master should also be corrupted on the slaves. Therefore, `REPAIR` is generally used with the `NO_WRITE_TO_BINLOG` option, to avoid replicating it to the slaves.

Partitioned Tables

Partitioned tables are normally split into multiple physical files (one per partition). Even if one of the partitions is corrupted, in most cases other partitions are healthy.

For this reason, `CHECK TABLE` and `REPAIR TABLE` don't work on partitioned tables. Instead, use ALTER TABLE to check or repair a single partition.

For example:

```
ALTER TABLE orders CHECK PARTITION p_2019, p_2020;
ALTER TABLE orders REPAIR PARTITION p_2019, p_2020;
```

Indexes

Indexes can get corrupted. However, as long as data is not corrupted, indexes can always be dropped and rebuilt with ALTER TABLE:

```
ALTER TABLE customer DROP INDEX idx_email;
ALTER TABLE customer ADD INDEX idx_email (email);
```

Checking and Repairing Tables

Here we discuss how to repair tables, depending on the storage engine.

InnoDB

InnoDB follows the "fail fast" philosophy. If table corruption is detected, by default InnoDB deliberately causes MariaDB to crash to avoid corruption propagation, logging an error into the error log. This happens even if the corruption is found with a `CHECK TABLE` statement. This behavior can be changed with the innodb_corrupt_table_action server variable.

To repair an InnoDB table after a crash:

1. Restart MariaDB with the –innodb-force-recovery option set to a low but non-zero value.
2. If MariaDB fails to start, retry with a higher value. Repeat until you succeed.

At this point, you can follow two different procedures, depending if you can use a backup or not. Provided that you have a usable backup, it is often the best option to bring the database up quickly. But if you want to reduce the data loss as much as possible, you prefer to follow the second method.

Restoring a backup:

1. Drop the whole database with DROP DATABASE.
2. Restore a backup of the database. The exact procedure depends on the type of backup.

Recovering existing data:

1. Dump data from the corrupter table, ordered by primary key. MariaDB could crash when it finds damaged data. Repeat the process skipping damaged data.
2. Save somewhere the table structure with SHOW CREATE TABLE.
3. Restart MariaDB.
4. Drop the table with DROP TABLE.
5. Recreate the table and restore the dump.

For more details, see InnoDB Recovery Modes.

Aria and MyISAM

MyISAM is not crash-safe. In case of a MariaDB crash, the changes applied to MyISAM tables but not yet flushed to the disk are lost.

Aria is crash-safe by default, which means that in case of a crash, after repairing any table that is damaged, no changes are lost. However, Aria tables are not crash-safe if created with `TRANSACTIONAL=0` or `ROW_FORMAT` set to `FIXED` or `DYNAMIC`.

System tables use the Aria storage engine and they are crash-safe.

To check if a MyISAM/Aria table is corrupted, we can use CHECK TABLE. To repair a MyISAM/Aria table, one can use REPAIR TABLE. Before running `REPAIR TABLE` against big tables, consider increasing myisam_repair_threads or aria_repair_threads.

MyISAM and Aria tables can also be automatically repaired when corruption is detected. This is particularly useful for Aria, in case corrupted system tables prevent MariaDB from starting. See myisam_recover_options and aria_recover_options. By default Aria runs the quickest repair type. Occasionally, to repair a system table, we may have to start MariaDB in this way:

```
mysqld --aria-recover-options=BACKUP,FORCE
```

It is also possible to stop MariaDB and repair MyISAM tables with myisamchk, and Aria tables with aria_chk. With default values, a repair can be unnecessarily very slow. Before running these tools, be sure to check the Memory and Disk Use With myisamchk page.

Other Storage Engines

Notes on the different storage engines:

- For MyRocks, see MyRocks and CHECK TABLE.
- With ARCHIVE, `REPAIR TABLE` also improves the compression rate.
- For CSV, see Checking and Rpairing CSV Tables.
- Some special storage engines, like MEMORY or BLACKHOLE, do not support any form of check and repair.

Setting Up MariaDB for Testing for SQL Server Users

This page contains links and hints to setup MariaDB for testing. The page is designed for SQL Server users, assuming that they are mostly familiar with Windows and they are not familiar with MariaDB.

Choosing a MariaDB Version

As a general rule, for new installations it's better to choose the latest Generally Available (GA) version.

If you need a feature that is only present in a version that is not yet production-ready, and the project will surely not go to production before that version is GA, it could make sense to use a non-GA version. In this case however, keep in mind that you are using a version that is only suitable for testing.

If you need to work with an existing production instance, you should of course use the same version in testing. However, deprecated versions should not be used in production, because they could be exposed to vulnerabilities that will never be fixed. See deprecation policies if you are not sure about the version you are using.

Setting up MariaDB on Windows

There are two different ways to use MariaDB on Windows natively: using Zip packages or MSI packages.

In both cases, 32-bit platforms are still supported.

Check the page Installation issues on Windows to verify if current versions of MariaDB have troubles on Windows. More generally, it is a good idea to check the Troubleshooting Installation Issues category.

ZIP Packages

Windows users don't necessarily need to install MariaDB to use it. They can download ready-to-use ZIP packages to avoid any change in the system (except for downloading MariaDB and writing databases on the disk). This is very useful for testing without risking some undesired side effect on the machine in use. And it avoids the hassle of installing Docker or virtual machines.

It is necessary to run mysql_install_db.exe to install the data directory.

The drawback is that MariaDB will need to be started and stopped from the command line.

See Installing MariaDB Windows ZIP Packages.

MSI Packages

MSI packages provide a friendly graphical interface to install MariaDB. The installation process is easy but flexible. For example, the user can decide which components to install, whether to install it as a service or not, and if networking should be enabled. An interface to uninstall MariaDB is also provided.

See Installing MariaDB MSI Packages on Windows.

Installing MariaDB on Docker

Docker is a container platform that runs natively on Linux. A Docker image is a representation of a basic Linux system, which usually runs a single process - in our case, that process is MariaDB. A container is an instance of an image, which can be created or destroyed instantaneously. Once a container is started, it can be used just like a normal system.

Docker runs on all major operating systems. On Windows and MacOS it runs on a Linux virtual machine, but this additional complexity is transparent for the end user.

Docker's characteristics makes it optimal to test MariaDB functionalities without wasting time on installation and without making changes to the host system. However, it is not ideal to test MariaDB performance.

See Installing and Using MariaDB via Docker.

Reinitializing MariaDB Data Directory

While experimenting with MariaDB, you could end up with an unusable installation. This occurs for example if you deliberately delete files that you shouldn't delete. If it happens, there is no need to uninstall and reinstall MariaDB.

Instead, you can simply delete the contents of the data directory and run mariadb-install-db. The program will recreate your system tables and the essential files.

To know where your data directory is, check the datadir system variable.

Migrating From MariaDB RDS to MariaDB Cloud

This guide covers migrating from a self-managed or AWS MariaDB RDS instance to MariaDB Cloud using AWS Database Migration Service (DMS), utilizing binary log streaming for Change Data Capture (CDC)[19] to enable a near-zero downtime cutover.

Phase 1: Preparing Your Source and Target Environments

DMS reads changes from MariaDB using binary log replication. These settings must be in place before creating DMS endpoints or starting any task.

Step 1

Source AWS MariaDB RDS Configuration

- Enable automated backups: Set *Backup Retention Period* to at least 1 day.
- Create a custom parameter group: Apply the following parameters to ensure DMS can read row-level changes:
- `binlog_format = ROW`
- `binlog_row_image = FULL`
- `binlog_checksum = NONE`

Option groups
default:mariadb-11-8 In sync

Amazon Resource Name (ARN)
arn:aws:rds:ap-south-1:221033228277:db:
database-1

Resource ID
db-Z6IHGACSNVD5Z63SP4IWC5JOMI

Created time
April 20, 2026, 10:31 (UTC+05:30)

DB instance parameter group
mariadb118custom In sync

- Apply and reboot: Associate the custom parameter group with your RDS instance and **reboot** to finalize the `ROW` mode.
- Set log retention: Provide a buffer for DMS to read the continuous logs. Run this command: `CALL mysql.rds_set_configuration('binlog retention hours', 24);`
- Verify that all of the following variables are set, by running the following statements:

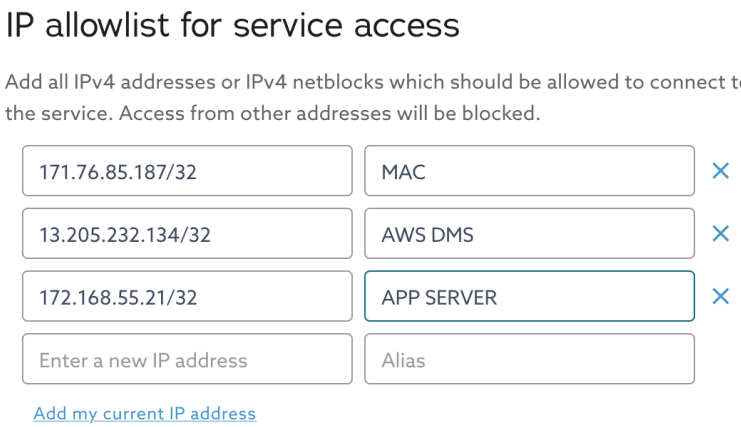
```
MariaDB [(none)]> SHOW VARIABLES LIKE 'net%';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| net_buffer_length | 16384 |
| net_read_timeout  | 30    |
| net_retry_count   | 10    |
| net_write_timeout | 60    |
+-------------------+-------+

MariaDB [(none)]> SHOW VARIABLES LIKE 'binlog_format';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| binlog_format | ROW   |
+---------------+-------+
```

Step 2

MariaDB Cloud Target Configuration

- Create database: Log into MariaDB Cloud and run `CREATE DATABASE db_name;`.
- Create user (optional): Use the default user to create additional users with privileges (for instance, users in RDS, `dms_admin` etc.), setting the Allowed Host to `%` or to the specific IP of your DMS instance.
- Verify settings: Issue the same `SHOW VARIABLES` statements as in the previous step.
- Enable connectivity: Open the MariaDB Cloud allowlist during setup, narrow it to the *NAT Gateway EIP* (or *DMS Public IP*) before go-live.

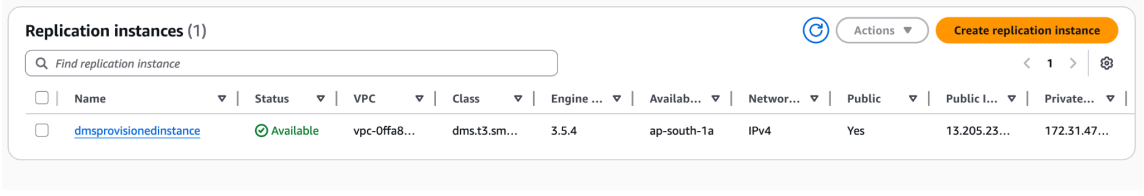


> **Note:**
>
> Note on Serverless: Unlike Provisioned instances, MariaDB Serverless creates temporary Elastic Network Interfaces (ENIs) in your subnets. These ENIs lack default Public IPs and cannot reach the internet via an Internet Gateway. A NAT Gateway in your VPC is required.

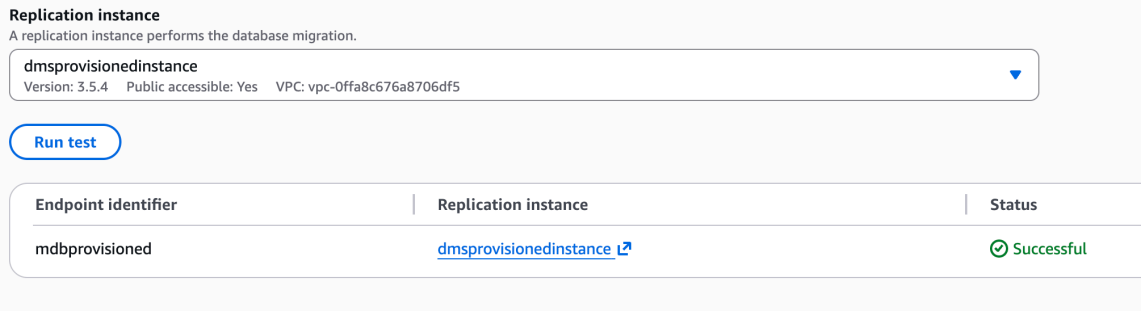
Phase 2: Provisioning the AWS DMS Networking and Compute

The replication instance is the compute resource that handles the data migration.

- Instance type: Using a *Provisioned* instance is highly recommended for static IP stability.
- VPC architecture: Deploy resources within private subnets for enhanced security, utilizing a NAT Gateway to establish the required outbound internet connection to MariaDB Cloud.
- Public accessibility: Select *Publicly Accessible: Yes* if your traffic is routing over the internet. Note the allocated *Public IP* and add it to your MariaDB Cloud allowlist if you are not using an open `0.0.0.0/0` rule.



- Test Connections: Ensure both endpoints return a *Successful* status.



> **Note:**
>
> Serverless Limits: Similar to the target database, DMS Serverless relies on ENIs without Public IPs and inherently struggles to reach MariaDB Cloud over the internet without a properly configured NAT Gateway.

Phase 3: Migrating Schema Definitions and Secondary Objects

AWS DMS only migrates table data and basic primary keys. It does not migrate secondary objects such as views, stored procedures, or triggers.

Export metadata from RDS source: Use `mariadb-dump` from your terminal to grab all schema objects except the table data. Run this command:

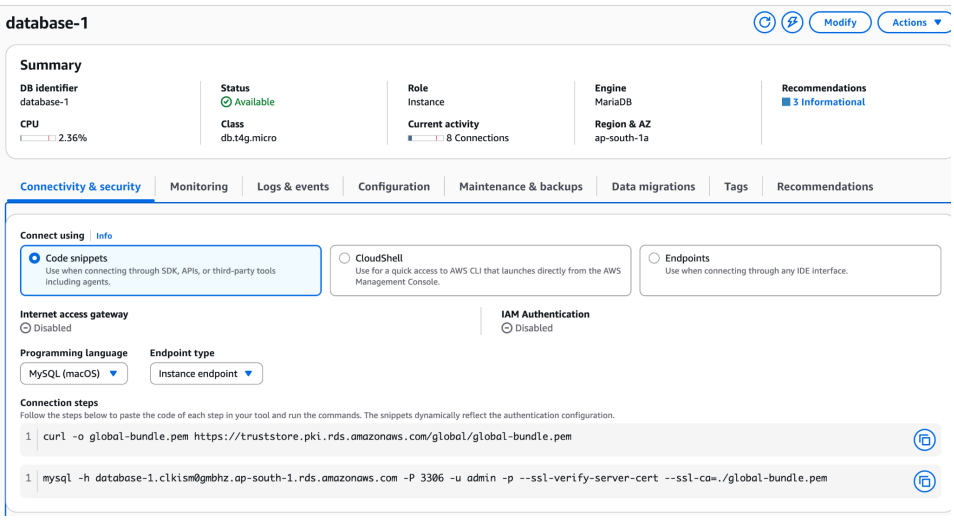
```
mariadb-dump
  -h [RDS_HOST] -u [USER] -p
  --no-data --no-create-info --routines --triggers
  --databases db_name | sed -e 's/DEFINER=`[^`]*`@`[^`]*`//g'  > metadata.sql
```

Phase 4: Configuring Migration Endpoints and Sync Tasks

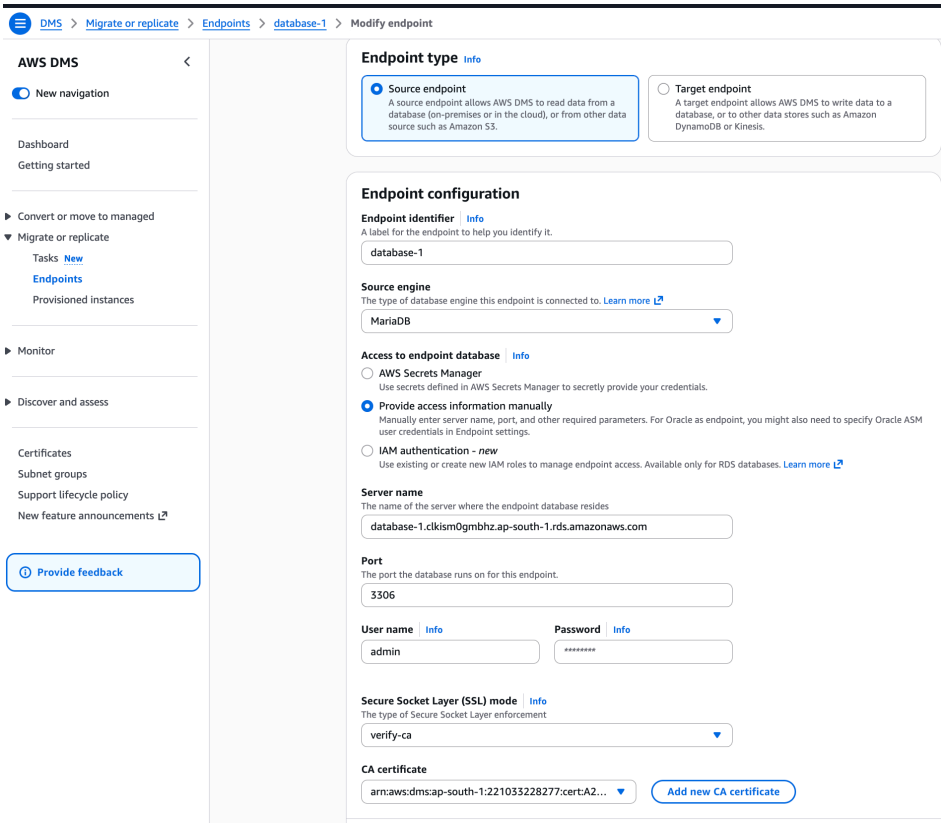
Before creating endpoints, establish secure CA certificate trust between AWS DMS and your database servers.

Source Endpoint (RDS)

1. Download the Global Bundle or Regional CA from the AWS RDS connection information section.

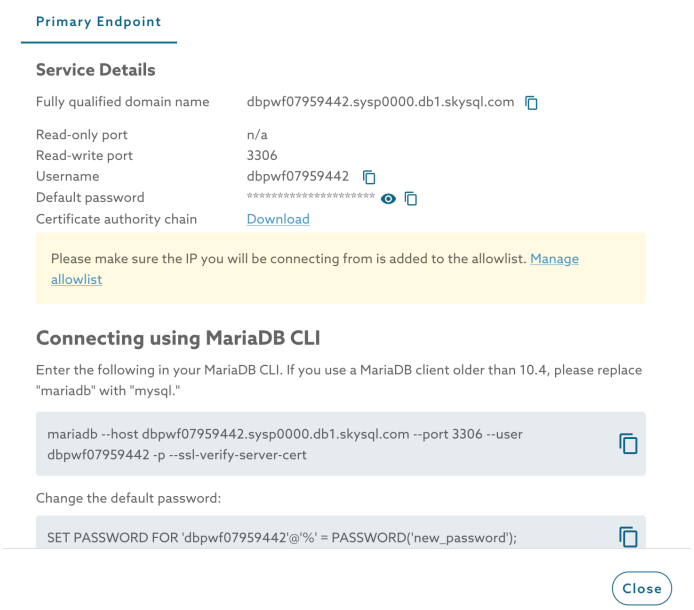


2. In the DMS Console, go to *Certificates* > *Import Certificate*. Upload the `global-bundle.pem` file and rename it to `rds-source-ca`.
3. In the *Source Endpoint* settings, select SSL mode: `verify-ca` and choose the `rds-source-ca` certificate. Point to your RDS endpoint using the MariaDB user.

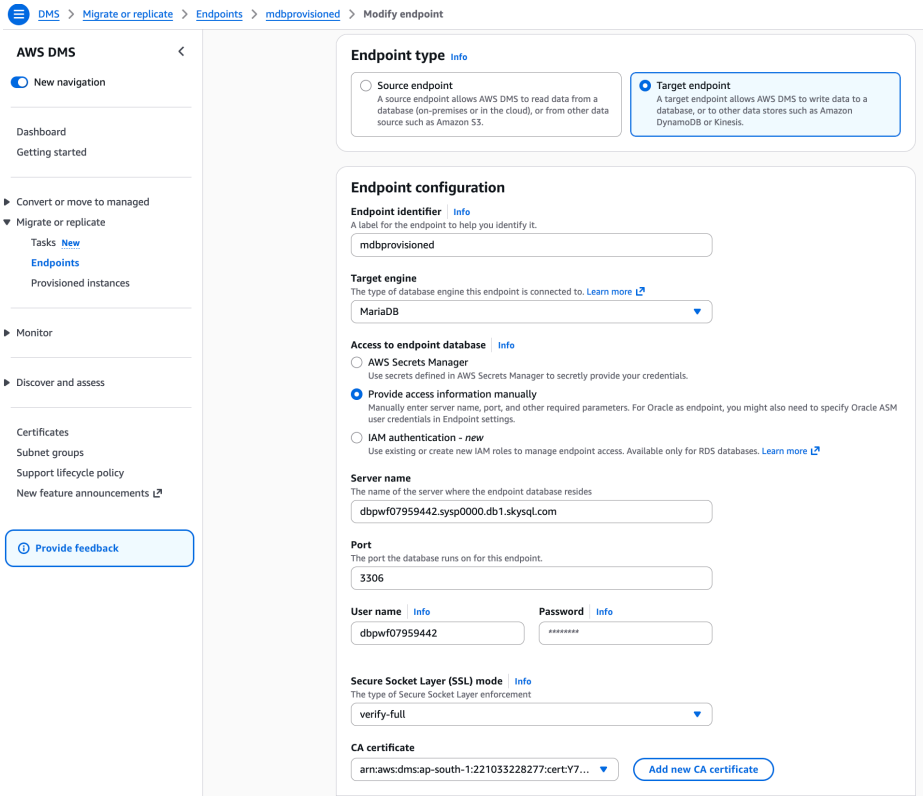


Target Endpoint (MariaDB Cloud)

1. Download the MariaDB Cloud CA Certificate from your MariaDB Cloud portal (found in the Security or Connect tab).



2. Import this into the DMS Console as MariaDB Cloud-target-ca.
3. Create the Target Endpoint, select SSL mode: `verify-full`, and point it to the MariaDB Cloud endpoint on Port `3306`.

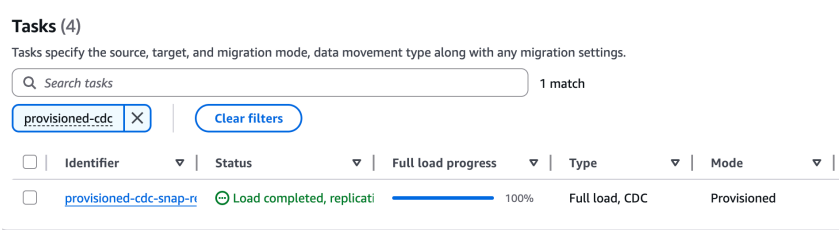


Create the DMS Migration Task

- Migration type: Select Migrate existing data and replicate ongoing changes (enables Snapshot + Replica mode).
- Target table preparation mode: Choose *Drop tables on target* if you want DMS to build the structures, or *Do nothing* if you precreated the tables.
- Stop task after full load completes: Select *Don't stop* so it transitions into CDC mode automatically.
- Include LOB columns in replication: Select *Limited LOB* mode.
- Table Mappings: Add a selection rule with *Schema <your Schema Name>*, *Table name* `%`, and *Action Include*.
- Transformation Rules: Add rules here if you need to rename schemas (for instance, rename `sakila` to `sakila_prod`).
- *Premigration Assessment*: Enable this to let AWS check for potential issues (unsupported data types, missing primary keys) before launching.

Phase 5: Live Replication, Target Cutover, and Decommissioning

1. Executing the *Snapshot + Replica:* Select *Start on create* to initiate the *Full Load*. Watch the *Full Load* progress bar until it hits 100%. The task status will transition to *Load complete, replication ongoing*. From this point forward, any `INSERT` or `UPDATE` statement on the RDS source is replicated to MariaDB Cloud instantaneously.



2. Post-table migration (views, triggers, and procedures): AWS DMS does not migrate secondary objects. Once DMS shows the load is complete, apply the metadata you exported in Part 3 to your MariaDB Cloud Instance:

```
mariadb -h [MariaDB Cloud_HOST] -P 4000 -u [USER] -p db_name < metadata.sql
```

> **Note:**
>
> Important CDC considerations for triggers: If you have triggers on the Target (MariaDB Cloud) that update other tables, DMS might accidentally trigger them again while replicating CDC events, causing duplicate data. It is best practice to keep triggers disabled on the target until the final cutover.

3. Cutover: Identify a low-traffic window, stop the application from writing to the RDS source, and wait for the CDC lag to hit zero. Update your connection strings to point to MariaDB Cloud, re-enable your triggers, and finally terminate the DMS task and infrastructure.

Phase 6 (Optional): Reverse Replication

Switch master and slave to make MariaDB Cloud the master.

Establishe MariaDB SkySQL as the primary (master) and AWS RDS as the replica (slave).

1. Prepare MariaDB Cloud (new master)

Before RDS can follow MariaDB Cloud, the target environment must be configured to allow inbound replication.

- Add the AWS RDS *Public IP* (or *NAT Gateway EIP*) to the SkySQL Allowlist (Port `3306`).
- Identity: Create a dedicated replication user on MariaDB Cloud (SkySQL):

```
CREATE USER 'repl_user'@'%' IDENTIFIED BY 'YourSecurePassword';
GRANT REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO 'repl_user'@'%';
```

- Checkpoint: Capture the current binary log coordinates to tell RDS where to start:

```
SHOW MASTER STATUS; -- note the file and position
```

2. Configure AWS RDS (new slave): Because RDS is a managed service, standard `CHANGE MASTER` statements are restricted. You must use AWS stored procedures.

- Initialize: Clear old migration metadata and point RDS to the SkySQL endpoint using the file and position from step 1:

```
CALL mysql.rds_set_external_master ('skysql-hostname.net', 4000, 'repl_user', 'YourSecurePassword',
'[File_from_SkySQL]', [Position_from_SkySQL], 1 );
```

- Activate: Start the replication threads:

```
CALL mysql.rds_start_replication;
```

3. Monitoring & verification: The “source of truth” for the health of this link moves from the DMS Console to the database command line.

- Status check on RDS: Run `CALL mysql.rds_replica_status\G;` to verify connectivity.
- Success criteria: Ensure `Slave_IO_Running` is `Yes`, `Slave_SQL_Running` is `Yes`, and `Seconds_Behind_Master` is `0`.
- Status check on MariaDB Cloud: Run `SHOW MASTER STATUS\G` and `SHOW SLAVE STATUS\G` (this should return an empty set).

Decommissioning: Once `Seconds_Behind_Master` remains at `0`, the AWS DMS infrastructure is redundant. To eliminate unnecessary costs:

1. Stop and Delete the AWS DMS Task.
2. Terminate the DMS Replication Instance.
3. Delete the NAT Gateway (if no longer required for outbound RDS traffic).

> **Note:**
>
> The DMS Task Console will now show *Zero Activity* and may report *High Source Latency*. This is expected, as the data flow has successfully moved from the DMS pipe to native MariaDB replication.

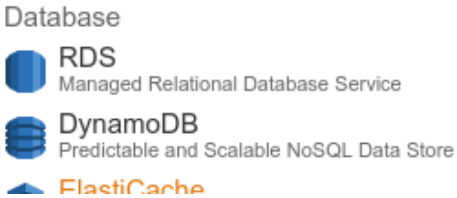
MariaDB on Amazon RDS

MariaDB is available on Amazon AWS, as one of the database options when using Amazon's RDS service, or using a MariaDB AMI on Amazon EC2 from the AWS Marketplace.

Amazon RDS

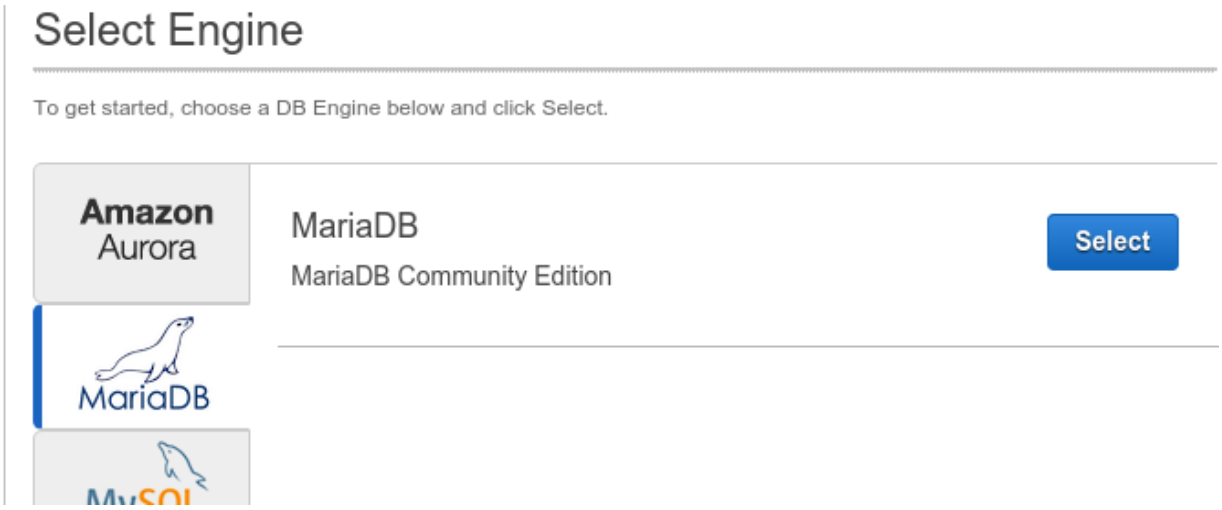
To get started with MariaDB on Amazon's RDS service, click on the RDS link in the Database section of the AWS console.



rds-link

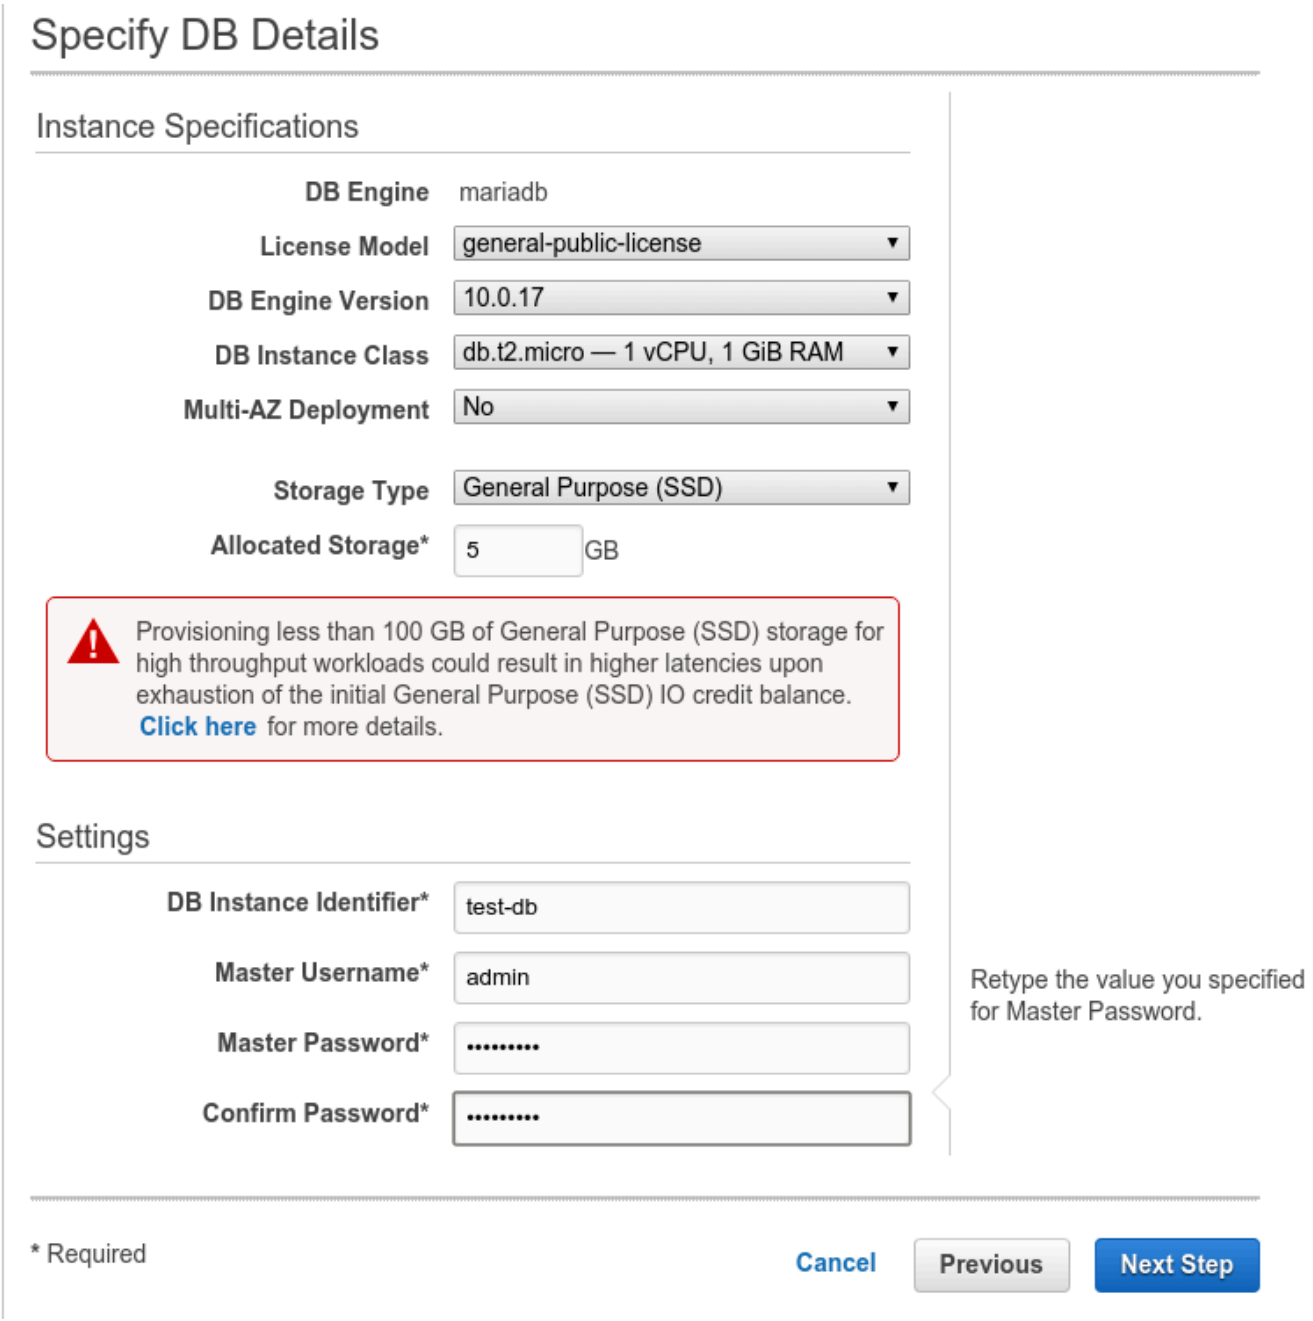
Next, click on the **Get Started Now** button. Alternatively, you can click on the **Launch DB Instance** button from the Instances section of the RDS Dashboard.

In either case, you will be brought to the page where you can select the database engine you want to use. Click on the **MariaDB** logo and then click on the **Select** button.



You will then move to step 2 where you choose whether or not you want to use your MariaDB instance for production or non-production usage. Amazon has links on this page to documentation on the various options.

After selecting the choice you want you will move to step 3 where you specify the details for your database, including setting up an admin user in the database.



You will then move to step 4 where you can configure advanced settings, including security settings, various options, backup settings, maintenance defaults, and so on.

Refer to Amazon's RDS documentation for complete documentation on all the various settings and for information on connecting to and using your RDS MariaDB instances.

AMI on EC2

MariaDB AMIs (Amazon Machine Images) are available in the AWS Marketplace. These AMIs, kept up-to-date with the most recently released versions of MariaDB, are a great way to try out the newest MariaDB versions before they make it to RDS and/or to use MariaDB in a more traditional server environment.

Complete Starting and Stopping Overview guide for MariaDB. Complete reference documentation for implementation, configuration, and usage for production use.

See launchd (macOS).

Instructions for configuring MariaDB to start automatically on macOS using a launchd plist file in /Library/LaunchDaemons.

See systemd (Linux).

MariaDB on systemd (Linux): overview, supported distributions, and links to operational and configuration guidance.

See sysVinit.

Describes how to manage MariaDB using SysVinit scripts (mysql.server), common on older Linux distributions, using commands like `service` and `chkconfig`.

See mariadbd-safe.

Details the `mariadbd-safe` wrapper script, which adds safety features like auto-restart upon crash and error logging to syslog.

See mariadbd-multi.

Explains how to use `mariadbd-multi` to manage multiple MariaDB server processes on a single host using GNR groups in the configuration file.

See mariadbd Options.

A reference list of command-line options available for the `mariadbd` server binary, covering configuration, replication, and service installation.

See mariadbd.

Describes the `mariadbd` binary (formerly `mysqld`), which is the core database server executable.

See mysql.server.

Documentation for the `mysql.server` script, a SysVinit-style wrapper used to start and stop `mariadbd-safe`.

See Running MariaDB From the Build Directory.

Instructions for developers on how to run MariaDB directly from the source build directory without installing it to system paths.

See Running Multiple MariaDB Server Processes.

A guide on configuring and running multiple independent MariaDB instances on the same machine by isolating data directories, ports, and sockets.

See Specifying Permissions for Schema (Data) Directories and Tables.

Explains default file permissions for data directories and how to customize them using `UMASK` and `UMASK_DIR` environment variables.

See Switching Between Different Installed MariaDB Versions.

Techniques for managing parallel installations of different MariaDB versions, typically using symlinks and separate data directories for testing.

See What to Do if MariaDB Doesn't Start.

Complete What to Do if MariaDB Doesn't Start guide for MariaDB. Complete reference documentation for implementation, configuration, and usage.

This page is licensed: CC BY-SA / Gnu FDL

Starting and Stopping Overview

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually.

Service Managers

sysVinit and systemd are the most common Linux service managers. launchd is used in MacOS X. Upstart is a less common service manager.

Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use systemd by default.

For information on how to start and stop MariaDB with this service manager, see systemd: Interacting with the MariaDB Server Process.

SysVinit

RHEL/CentOS 6 and below, and Debian 7 Wheezy and below use sysVinit by default.

For information on how to start and stop MariaDB with this service manager, see sysVinit: Interacting with the MariaDB Server Process.

launchd

launchd is used in MacOS X.

Upstart

Ubuntu 14.10 and below use Upstart by default.

Starting the Server Process Manually

mariadbd

mariadbd is the actual MariaDB Server binary. It can be started manually on its own.

mariadbd-safe

mariadbd-safe is a wrapper that can be used to start the mariadbd server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See mariadbd-safe for more information.

mariadbd-multi

mariadbd-multi is a wrapper that can be used to start the mariadbd server process if you plan to run multiple server processes on the same host. See mariadbd-multi for more information.

mysql.server

mysql.server is a wrapper that works as a standard sysVinit script. However, it can be used independently of sysVinit as a regular `sh` script. The script starts the mariadbd server process by first changing its current working directory to the MariaDB install directory and then starting mariadbd-safe. The script requires the standard sysVinit arguments, such as `start`, `stop`, and `status`. See mysql.server for more information.

This page is licensed: CC BY-SA / Gnu FDL

launchd (macOS)

If you install MariaDB on macOS using Homebrew – which is the only option – starting and stopping `mariadbd` (MariaDB server) is done as described on this page. The below instructions don't need to be performed.

On macOS, create a file called `/Library/LaunchDaemons/com.mariadb.server.plist` with the following contents (edit to suit):

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-
1.0.dtd">
<plist version="1.0">
<dict>
  <key>Label</key> <string>com.mariadb.server</string>
  <key>KeepAlive</key><true/>
  <key>RunAtLoad</key><true/>
  <key>LaunchOnlyOnce</key><false/>
  <key>ExitTimeOut</key><integer>600</integer>
  <key>WorkingDirectory</key><string>/usr/local/var</string>
  <key>Program</key><string>/usr/local/bin/mysqld</string>
  <key>ProgramArguments</key>
  <array>
    <string>/usr/local/bin/mysqld</string>
    <string>--user=_mysql</string>
    <string>--basedir=/usr/local/opt/mariadb</string>
    <string>--plugin-dir=/usr/local/opt/mariadb/lib/plugin</string>
    <string>--datadir=/usr/local/var/mysql</string>
    <string>--log-error=/usr/local/var/mysql/Data-Server.local.err</string>
    <string>--pid-file=/usr/local/var/mysql/Data-Server.local.pid</string>
    <string>--sql-mode=ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION</string>
  </array>
</dict>
</plist>
```

Then from a shell, run `launchctl load /Library/LaunchDaemons/com.mariadb.server.plist` and MariaDB will run immediately, and also upon reboot.

This page is licensed: CC BY-SA / Gnu FDL

systemd (Linux)

`systemd` is a sysVinit replacement that is the default service manager on the following Linux distributions:

- RHEL 7 and above
- CentOS 7 and above
- Fedora 15 and above
- Debian 8 and above
- Ubuntu 15.04 and above
- SLES 12 and above
- OpenSUSE 12.2 and above

MariaDB's `systemd` unit file is included in the server packages for RPMs and DEBs. It is also included in certain binary tarballs.

The service name is `mariadb.service`.

In this Section

See Starting MariaDB on systemd.

Installing, starting, stopping, restarting, and inspecting the MariaDB service, including multi-instance setups, Galera Cluster integration, and the systemd journal.

See Configuring MariaDB for systemd.

Drop-in configuration files, timeouts, open-file and core-size limits, `LimitMEMLOCK` (`io_uring` and `aio`), error-log redirection, home-directory access, umask, data directory, socket activation, and converting `mariadbd-safe` options to `systemd` options. Also includes a quick-setup script for developers running MariaDB from a build directory.

Contents of the MariaDB Service's Unit File

The contents of the `mariadb.service` file can be examined with `systemctl show mariadb.service`.

This page is licensed: CC BY-SA / Gnu FDL

Starting MariaDB on systemd

This page covers the operational side of running MariaDB under systemd. For drop-in configuration, limits, socket activation, and `mariadbd-safe`-to-systemd conversion, see Configuring MariaDB for systemd.

Installing & Starting MariaDB

When installing using the MariaDB server RPM or DEB package, it automatically runs the mariadb-install-db script which creates the initial databases and users.

When MariaDB is started with the `systemd` unit file, it directly starts the mariadbd process as the `mysql` user. Unlike with sysVinit, the mariadbd process is not started with mariadbd-safe. As a consequence, options are not read from the `[mariadbd-safe]` option group from option files.

Interacting with the MariaDB Server Process

The service can be interacted with by using the systemctl command.

Starting the MariaDB Server Process on Boot

MariaDB's `systemd` service can be configured to start at boot by executing the following:

```
sudo systemctl enable mariadb.service
```

Starting the MariaDB Server Process

MariaDB's `systemd` service can be started by executing the following:

```
sudo systemctl start mariadb.service
```

MariaDB's `systemd` unit file has a default startup timeout of about 90 seconds on most systems. If certain startup tasks, such as crash recovery, take longer than this default startup timeout, then `systemd` assumes that `mariadbd` has failed to startup, which causes `systemd` to kill the `mariadbd` process. To work around this, you can reconfigure the MariaDB `systemd` unit to have an infinite timeout.

Note that systemd 236 added the EXTEND_TIMEOUT_USEC environment variable that allows services to extend the startup timeout during long-running processes. On systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long. Therefore, if you are using `systemd` 236 or later, then you should not need to manually override `TimeoutStartSec`, even if your startup tasks, such as crash recovery, run for longer than the configured value. See MDEV-14705 for more information.

Stopping the MariaDB Server Process

MariaDB's `systemd` service can be stopped by executing the following:

```
sudo systemctl stop mariadb.service
```

Restarting the MariaDB Server Process

MariaDB's `systemd` service can be restarted by executing the following:

```
sudo systemctl restart mariadb.service
```

Checking the Status of the MariaDB Server Process

The status of MariaDB's `systemd` service can be obtained by executing the following:

```
sudo systemctl status mariadb.service
```

Interacting with Multiple MariaDB Server Processes

On some operating systems, a `systemd` template unit file called `mariadb@.service` is installed in `INSTALL_SYSTEMD_UNITDIR`. See Contents of the MariaDB Service's Unit File for how to inspect the unit file on your system.

This template unit file allows you to interact with multiple MariaDB instances on the same system using the same template unit file. When you interact with a MariaDB instance using this template unit file, you have to provide an instance name as a suffix. For example, the following command tries to start a MariaDB instance with the name `node1`:

```
sudo systemctl start mariadb@node1.service
```

MariaDB's build system cannot include the `mariadb@.service` template unit file in RPM packages on platforms that have cmake versions older than 3.3.0, because these `cmake` versions have a bug that causes it to encounter errors when packaging a file in RPMs if the file name contains the `@` character. To use this functionality on a MariaDB version that does not have the file, you can copy the file from a package that contains the file.

Default Configuration of Multiple Instances

`systemd` also looks for an option file for a specific MariaDB instance based on the instance name.

It uses the `.%I` as the custom option group suffix that is appended to any server option group, in any configuration file included by default.

In all distributions, the `%I` is the MariaDB instance name. In the above `node1` case, it would use the option file at the path `/etc/mynode1.cnf`.

When using multiple instances, each instance also needs their own datadir, socket, and port (unless `skip_networking` is specified). Because mariadb-install-db reads the same sections as the server, and `ExecStartPre=run mariadb-install-db` within the service, the instances are automatically created if there are sufficient privileges.

Custom Configuration of Multiple Instances

Because users may want to do many various things with their multiple instances, we've provided a way to let the user define how they wish their multiple instances to run. The systemd environment variable `MYSQLD_MULTI_INSTANCE` can be set to anything that mariadbd and mariadb-install-db recognize.

A hosting environment where each user has their own instance looks like this (with `sudo systemctl edit mariadb@.service`):

```
[Service]
ProtectHome=false
Environment='MYSQLD_MULTI_INSTANCE=--defaults-file=/home/%I/my.cnf \
                        --user=%I \
                        --socket=/home/%I.sock \
                        --datadir=/home/%I/mariadb_data \
                        --skip-networking'
```

Here the instance name is the unix user of the service.

Systemd and Galera Cluster

Bootstrapping a New Cluster

When using Galera Cluster with systemd, the first node in a cluster has to be started with `galera_new_cluster`. See Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster for more information.

Recovering a Node's Cluster Position

When using Galera Cluster with systemd, a node's position in the cluster can be recovered with `galera_recovery`. See Getting Started with MariaDB Galera Cluster: Determining the Most Advanced Node for more information.

SSTs and Systemd

MariaDB's `systemd` unit file has a default startup timeout of about 90 seconds on most systems. If an SST takes longer than this default startup timeout on a joiner node, then `systemd` assumes that `mariadbd` has failed to startup, which causes `systemd` to kill the `mariadbd` process on the joiner node. To work around this, you can reconfigure the MariaDB `systemd` unit to have an infinite timeout. See Introduction to State Snapshot Transfers (SSTs): SSTs and Systemd for more information.

Note that systemd 236 added the EXTEND_TIMEOUT_USEC environment variable that allows services to extend the startup timeout during long-running processes. On systems with `systemd` versions that support it, MariaDB uses this feature to extend the startup timeout during long SSTs. Therefore, if you are using `systemd` 236 or later, you do not need to manually override `TimeoutStartSec` even if your SSTs run for longer than the configured value. See MDEV-15607 for more information.

Systemd Journal

`systemd` has its own logging system called the `systemd` journal. The `systemd` journal contains information about the service startup process. It is a good place to look when a failure has occurred.

The MariaDB `systemd` service's journal can be queried by using the journalctl command:

```
$ sudo journalctl n 20 -u mariadb.service
-- Logs begin at Fri 2019-01-25 13:49:04 EST, end at Fri 2019-01-25 18:07:02 EST. --

Configuring MariaDB for systemd

This page covers configuration for MariaDB running under systemd. For starting, stopping, and inspecting the service, see Starting MariaDB on systemd.

> **Note:**
>
> The per-option sections on this page apply to **installed-service deployments** — MariaDB started via `mariadb.service`. If you are a developer running `mariadbd` from a build directory (for example, running `mysql-test-run`), most of those settings don't apply, because your workflow doesn't go through `mariadb.service`. See Configuring systemd for MariaDB Development below for a one-shot setup script that covers the developer case.

Configuring systemd for MariaDB Development

When developing MariaDB, you typically run `mariadbd` directly from a build directory rather than installing it as a service. In that case, the per-service drop-in files described below (under `/etc/systemd/system/mariadb.service.d/`) have no effect, because no `mariadb.service` is involved. Instead, the limits need to be set in `systemd`'s system-wide manager configuration (`/etc/systemd/system.conf.d/`), `sysctl`, and PAM.

The following script applies the settings that are typically needed to run `mariadbd` and `mysql-test-run` (`mtr`) on a developer workstation, including support for `io_uring` asynchronous I/O in InnoDB, a sufficient number of open files, large core dumps, the `aio` limit fix for `mtr`, predictable core file locations, and `perf` / `rr` access. Run it as root:

```
#!/bin/bash
#
# Fixes needed for openSUSE (systemd) to be able to run and develop MariaDB
# without having to install it as a service
# This script needs to be run as root

set -e

# ── systemd limits ──────────────────────────────────────────────────────────

mkdir -p /etc/systemd/system.conf.d

cat > /etc/systemd/system.conf.d/memlock.conf << 'EOF'
# Needed for io_uring asynchronous IO used by InnoDB
[Manager]
DefaultLimitMEMLOCK=infinity
EOF

cat > /etc/systemd/system.conf.d/nofile.conf << 'EOF'
# Databases need a lot of open files
[Manager]
DefaultLimitNOFILE=65535
EOF

cat > /etc/systemd/system.conf.d/bigcore.conf << 'EOF'
# Allow big cores (needed to be able to debug MariaDB core files)
[Manager]
LimitCORE=infinity
EOF

# Apply systemd changes
systemctl daemon-reexec

# ── sysctl ──────────────────────────────────────────────────────────────────

mkdir -p /etc/sysctl.d

cat > /etc/sysctl.d/50-aio.conf << 'EOF'
# Fix "io_setup(1024) returned Unknown error -11 when running mtr tests"
fs.aio-max-nr=1048576
EOF

cat > /etc/sysctl.d/50-coredump.conf << 'EOF'
# Store core files in the current directory
kernel.core_pattern=core.%p
EOF

cat > /etc/sysctl.d/50-perf_event_paranoid.conf << 'EOF'
# Allow usage of perf/RR
kernel.perf_event_paranoid=1
EOF

# Apply sysctl changes
sysctl --system

# ── PAM limits ──────────────────────────────────────────────────────────────

mkdir -p /etc/security/limits.d

cat > /etc/security/limits.d/nofile.conf << 'EOF'
# Takes effect on next login
*    soft    nofile    65535
*    hard    nofile    65535
root soft    nofile    65535
root hard    nofile    65535
EOF

echo ""
```

```
echo "Done. PAM (number of open files) limits (/etc/security/limits.d/nofile.conf) will take effect on
next login."
```

Warning:

The PAM limit change in `/etc/security/limits.d/nofile.conf` only takes effect on your next login. Log out and back in (or open a new shell session) before running `mtr`.

Configuring the Systemd Service

You can configure MariaDB's `systemd` service by creating a "drop-in" configuration file for the `systemd` service. On most systems, the `systemd` service's directory for "drop-in" configuration files is `/etc/systemd/system/mariadb.service.d/`. You can confirm the directory and see what "drop-in" configuration files are currently loaded by executing:

```
$ sudo systemctl status mariadb.service
● mariadb.service - MariaDB 10.1.37 database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; enabled; vendor preset: disabled)
  Drop-In: /etc/systemd/system/mariadb.service.d
           └─migrated-from-my.cnf-settings.conf, timeoutstartsec.conf
...
```

If you want to configure the `systemd` service, you can create a file with the `.conf` extension in that directory. The configuration options you would like to change need to be placed in an appropriate section within the file, usually `[Service]`. If a `systemd` option is a list, you may need to set the option to empty before you set the replacement values:

```
[Service]

ExecStart=
ExecStart=/usr/bin/numactl --interleave=all  /usr/sbin/mariadbd $MYSQLD_OPTS $_WSREP_NEW_CLUSTER
$_WSREP_START_POSITION
```

After any configuration change, you need to execute the following for the change to take effect:

```
sudo systemctl daemon-reload
```

Useful Systemd Options

Useful `systemd` options are listed below. If an option is equivalent to a common mariadbd-safe option, then that is also listed. Use `systemctl edit mariadb.service` to create the systemd option under a `[Service]` section header.

mariadbd-safe option	systemd option	Comments
no option	ProtectHome=false	If any MariaDB files are in `/home/`
no option	PrivateDevices=false	If any MariaDB storage references raw block devices
no option	ProtectSystem=	If any MariaDB write any files to anywhere under `/boot`, `/usr` or `/etc`
no option	TimeoutStartSec={time}	Service startup timeout. See Configuring the Systemd Service Timeout.
no option (see MDEV-9264)	OOMScoreAdjust={priority}	For instance, `-600` to lower priority of OOM killer for `mariadbd`

mariadbd-safe option	systemd option	Comments
open-files-limit	LimitNOFILE={limit}	Limit on number of open files. See Configuring the Open Files Limit.
core-file-size	LimitCORE={size}	Limit on core file size. Useful when enabling core dumps. See Configuring the Core File Size.
	LimitMEMLOCK={size} or infinity	Limit on how much can be locked in memory. Useful when large-pages or memlock is used
nice	Nice={nice value}	
syslog	StandardOutput=syslog	See Configuring MariaDB to Write the Error Log to Syslog.
	StandardError=syslog	
	SyslogFacility=daemon	
	SyslogLevel=err	
syslog-tag	SyslogIdentifier	
flush-caches	ExecStartPre=/usr/bin/sync	
	ExecStartPre=/usr/sbin/sysctl -q -w vm.drop_caches=3	
malloc-lib	Environment=LD_PRELOAD=/path/to/library	
numa-interleave	NUMAPolicy=interleave	from systemd v243 onwards
	or: ExecStart=/usr/bin/numactl –interleave=all /usr/sbin/mariadbd $MYSQLD_OPTS $_WSREP_NEW_CLUSTER $_WSREP_START_POSITION	prepending ExecStart=/usr/bin/numactl –interleave=all to existing ExecStart setting
no-auto-restart	Restart={exit-status}	

> **Note:**
>
> The systemd manual contains the official meanings for these options. The manual also lists considerably more options than the ones listed above.

There are other options and the `mariadb-service-convert` script attempts to convert these as accurately as possible.

Configuring the Systemd Service Timeout

MariaDB's systemd unit file has a default startup timeout of about 90 seconds on most systems. If a service startup takes longer than this default startup timeout, then `systemd` assumes that `mariadbd` has failed to startup, which causes `systemd` to kill the `mariadbd` process. To work around this, it can be changed by configuring the TimeoutStartSec option for the `systemd` service.

A similar problem can happen when stopping the MariaDB service. Therefore, it may also be a good idea to set TimeoutStopSec.

For example, you can reconfigure the MariaDB `systemd` service to have an infinite timeout by executing one of the following commands:

If you are using `systemd` 228 or older, then you can execute the following to set an infinite timeout:

```
sudo systemctl edit mariadb.service

[Service]

TimeoutStartSec=0
TimeoutStopSec=0
```

Systemd 229 added the infinity option, so if you are using `systemd` 229 or later, you can execute the following to set an infinite timeout:

```
sudo systemctl edit mariadb.service

[Service]

TimeoutStartSec=infinity
TimeoutStopSec=infinity
```

Note that systemd 236 added the EXTEND_TIMEOUT_USEC environment variable that allows services to extend the startup timeout during long-running processes. On systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long, like when upgrading MariaDB to a newer main version or recovering after a crash with a very big transaction that needs to roll back.

Configuring the Open Files Limit

When using `systemd`, rather than setting the open files limit by setting the open-files-limit option for `mariadbd-safe` or the open_files_limit system variable, the limit can be changed by configuring the LimitNOFILE option for the MariaDB `systemd` service. The default is set to `LimitNOFILE=16364` in `mariadb.service`.

For example, you can reconfigure the MariaDB `systemd` service to have a larger limit for open files by executing the following command – then restart the server for the changes to take effect:

```
sudo systemctl edit mariadb.service

[Service]
LimitNOFILE=infinity
```

> **Note:**
>
> Setting `LimitNOFILE=infinity` doesn't actually set the open file limit to *infinite*.

In `systemd` 234 and later, setting `LimitNOFILE=infinity` actually sets the open file limit to the value of the kernel's `fs.nr_open` parameter. Therefore, in these `systemd` versions, you may have to change this parameter's value.

The value of the `fs.nr_open` parameter can be changed permanently by setting the value in /etc/sysctl.conf and restarting the server.

The value of the `fs.nr_open` parameter can be changed temporarily by executing the sysctl utility:

```
sudo sysctl -w fs.nr_open=1048576
```

In `systemd` 233 and before, setting `LimitNOFILE=infinity` actually sets the open file limit to `65536`. See systemd issue #6559 for more information. Therefore, in these `systemd` versions, it is not generally recommended to set `LimitNOFILE=infinity`. Instead, it is generally better to set `LimitNOFILE` to a very large integer. For example:

```
sudo systemctl edit mariadb.service

[Service]
LimitNOFILE=1048576
```

Configuring the Core File Size

When using `systemd`, if you would like to enable core dumps, rather than setting the core file size by setting the core-file-size option for `mariadbd-safe`, the limit can be changed by configuring the LimitCORE option for the MariaDB `systemd` service. For example, you can reconfigure the MariaDB `systemd` service to have an infinite size for core files by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]
LimitCORE=infinity
```

Configuring MariaDB to Write the Error Log to Syslog

When using `systemd`, if you would like to redirect the error log to the syslog, then that can easily be done by doing the following:

- Ensure that log_error system variable is not set.
- Set StandardOutput=syslog.
- Set StandardError=syslog.
- Set SyslogFacility=daemon.
- Set SysLogLevel=err.

For example:

```
sudo systemctl edit mariadb.service

[Service]
StandardOutput=syslog
StandardError=syslog
SyslogFacility=daemon
SysLogLevel=err
```

If you have multiple instances of MariaDB, then you may also want to set SyslogIdentifier with a different tag for each instance.

Configuring LimitMEMLOCK

Configuring Support for io_uring Asynchronous IO in InnoDB

If using `--memlock`, or the `io_uring` `asynchronous` IO in InnoDB in MariaDB 10.6 or above, with a Linux Kernel version < 5.12, you need to raise the `LimitMEMLOCK` limit.

```
sudo systemctl edit mariadb.service

[Service]
LimitMEMLOCK=2M
```

Increasing the Limit for aio

When running the server with lots of users, the default `aio` value is too small. When running `mysql-test-run`, you could see an error like this:

```
io_setup(1024) returned Unknown error -11
```

The fix is to configure a higher aio value:

1. Create this file: `/etc/sysctl.d/50-aio.conf`

2. Add the following to that file:

```
# Fix "io_setup(1024) returned Unknown error -11 when running mtr tests"
fs.aio-max-nr=1048576
```

Configuring Access to Home Directories

MariaDB's systemd unit file restricts access to `/home`, `/root`, and `/run/user` by default. This restriction can be overridden by setting the ProtectHome option to `false` for the MariaDB `systemd` service. This is done by creating a "drop-in" directory `/etc/systemd/system/mariadb.service.d/` and in it a file with a `.conf` suffix that contains the `ProtectHome=false` directive.

You can reconfigure the MariaDB `systemd` service to allow access to `/home` by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]

ProtectHome=false
```

Configuring the umask

When using `systemd`, the default file permissions of `mariadbd` can be set by setting the `UMASK` and `UMASK_DIR` environment variables for the `systemd` service. For example, you can configure the MariaDB `systemd` service's umask by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]

Environment="UMASK=0750"
Environment="UMASK_DIR=0750"
```

These environment variables do not set the umask. They set the default file system permissions. See MDEV-23058 for more information.

Keep in mind that configuring the umask this way only affects the permissions of files created by the `mariadbd` process that is managed by `systemd`. The permissions of files created by components that are not managed by `systemd`, such as mariadb-install-db, are not affected.

See Specifying Permissions for Schema (Data) Directories and Tables for more information.

Configuring the Data Directory

When doing a standard binary tarball installation, the *datadir* is under `/usr/local/data`. However, the default `systemd` service file makes the whole `/usr` directory tree write protected.

When just copying the distributed service file a tarball install does not start up, complaining for instance about this:

```
[Warning] Can't create test file /usr/local/.../data/ubuntu-focal.lower-test
[ERROR] mariadbd: File '/usr/local/.../data/aria_log_control' not found (Errcode: 30 "Read-only file
system")
[ERROR] mariadbd: Got error 'Can't open file' when trying to use aria control file
'/usr/local/.../data/aria_log_control'
```

So when using a data directory under `/usr/local` that specific directory needs to be made writable for the service using the `ReadWritePaths` setting:

```
sudo systemctl edit mariadb.service

[Service]
ReadWritePaths=/usr/local/mysql/data
```

Systemd Socket Activation

> **Note:**
>
> Systemd socket activation is available from MariaDB 10.6.

MariaDB can use systemd's socket activation. This is an on-demand service for MariaDB that activates when required.

Systemd socket activation uses a `mariadb.socket` definition file to define a set of UNIX and TCP sockets. Systemd listens on these sockets, and when they are connected to, systemd starts the `mariadb.service` and hand over the socket file descriptors for MariaDB to process the connection.

MariaDB remains running at this point, and has all sockets available and process connections exactly like it did before 10.6.

When MariaDB is shut down, the systemd `mariadb.socket` remains active, and a new connection restarts the `mariadb.service`.

Using Systemd Socket Activation

To use MariaDB systemd socket activation, instead of enabling/starting `mariadb.service`, `mariadb.socket` is used instead.

So the following commands work exactly like the `mariadb.service` equivalents.

```
systemctl start mariadb.socket
systemctl enable mariadb.socket
```

These files alone only contain the UNIX and TCP sockets and basic network connection information to which the server is listening for connections. `@mariadb` is a UNIX abstract socket, which means it doesn't appear on the filesystem. Connectors based on MariaDB Connector/C is able to connect with these by using the socket name directly, provided the higher level implementation doesn't try to test for the file's existence first. Some connectors like PHP use `mysqlnd` that is a pure PHP implementation and as such are only able to connect to on filesystem UNIX sockets.

With systemd activated sockets there is only a file descriptor limit on the number of listening sockets that can be created.

When to Use Systemd Socket Activation

A common use case for systemd socket activated MariaDB is when there needs to be a quick boot up time. MariaDB needs to be ready to run, but it doesn't need to be running.

The ideal use case for systemd socket activation for MariaDB is for infrastructure providers running many multiple instances of MariaDB, where each instance is dedicated for a user.

Downsides to Using Systemd Socket Activation

From the time the connection occurs, the client is going to be waiting until MariaDB has fully initialized before MariaDB can process the awaiting connection. If MariaDB was previously hard shutdown and needs to perform an extensive InnoDB rollback, then the activation time may be larger than the desired wait time of the client connection.

Configuring Systemd Socket Activation

When MariaDB is run under systemd socket activation, the usual socket, port, and backlog system variables are ignored, as these settings are contained within the systemd socket definition file.

There is no configuration required in MariaDB to use MariaDB under socket activation.

The systemd options available are from the systemd documentation, however ListenStream and BackLog would be the most common configuration options.

As MariaDB isn't creating these sockets, the sockets don't need to be created with a `mysql` user. The sockets MariaDB may end up listening to under systemd socket activation, it may have not had the privileges to create itself.

Changes to the default `mariadb.socket` can be made in the same way as services, `systemctl edit mariadb.socket`, or using `/etc/systemd/system/mariadb.socket.d/someconfig.conf` files.

Extra Port

A `systemd` socket can be configured as an extra_port, by using `[FileDescriptorName=extra]` in the `.socket` file.

The `mariadb-extra.socket` file is already packaged and ready for use.

Multi-Instance Socket Activation

`mariadb@.socket` is MariaDB's packaged multi-instance definition. It creates multiple UNIX sockets based on the socket file started.

Starting `mariadb@bob.socket` uses the `mariadb@.socket` definition with `%I` within the definition replaced with "bob".

When something connects to a socket defined there, the `mariadb@bob.service` are started.

Systemd Socket Activation for Hosting Service Providers

A `systemd` socket activation service with multi-instance can provide an on-demand per user access to a hosting service provider's dedicated database. Here, "user" refers to the customer of the hosting service provider.

End User Benefits

This provides the following benefits for the user:

- Each user has their own dedicated instance with the following benefits:
  - The instance is free from the database contention of neighbors on MariaDB shared resources (table cache, connections, etc)
  - The user is free to change their own configuration of MariaDB, within the limits and permissions of the service provider.
  - Database service level backups, like mariadb-backup, are now directly available.
  - A user can install their own plugins.
  - The user can run a different database version to their neighbors.
  - If a user's neighbor triggers a fault in the server, the uder's instance isn't affected.
- The database runs as their unix user in the server facilitating:
  - User can directly migrate their MariaDB data directory to a different provider.
  - The user's data is protected from other users on a kernel level.

Hosting Service Provider Benefits

In addition to providing user benefits as a sales item, the following are additional benefits for the hosting service provider compared to a monolith service:

- Without passwords for the database, while still having security, support may be easier.
- When a user's database isn't active, there is no resource usage, only listening file descriptors by systemd.
- The socket activation transparently, with a minor startup time, starts the service as required.
- When the user's database hasn't had any activity after a time, it deactivates (MDEV-25282).
- Planned enhancements in InnoDB provide:
  - an on-demand consumption of memory (MDEV-25340 .
  - a proactive reduction in memory (MDEV-25341).
  - a memory resource pressure reduction in memory use (MDEV-24670).
- The service provider can still cap the user's database memory usage in a ulimit way that a user cannot override in settings.
- The service provider may choose a CPU/memory/IO based billing to the user on Linux `cgroup` accounting rather than the available comprared to the rather limited options in CREATE USER.
- Because a user's database shuts down when inactive, a database upgrade on the server does not take effect for the user until it passively shuts down, restarts, and then gets reactivated hence reducing user downtime..

Downsides to the Hosting Service Provider

The extra memory used by more instances. This is mitigated by the on-demand activation. The deactivation when idle, and improved InnoDB memory management.

With plenty of medium size database servers running, the Linux OOM kill has the opportunity to kill off only a small number of database servers running rather than everyones.

Configuration Items for a Per-User systemd Socket-Activitated Multi-Instance Service

From a server perspective the operation are as follows. To make the socket ready to connect and systemd listening to the socket, run these commands:

```
# systemctl start mariadb@username.socket
# systemctl start mariadb-extra@username.socket
```

To enable this on reboot (the same way as a `systemd` service):

```
# systemctl enable mariadb@username.socket
# systemctl enable mariadb-extra@username.socket
```

A MariaDB Template File

A global template file. Once installed as a user's `$HOME/.my.cnf` file, it becomes the default for many applications and for the MariaDB server itself.

```
# cat /etc/my.cnf.templ
[client]
socket=/home/USER/mariadb.sock

[client-server]
user=USER

[mariadbd]
datadir=/home/USER/mariadb-datadir
```

Custom Configuration for the Multi-Instance Service

This extends/modifies the MariaDB multi-instance service.

The features of this extension are:

- It automatically creates configuration file for user applications.
- It installs the database on first service start.
- `auth-root-*` in mariadb-install-db means that the user is their own privileged user with unix socket authentication active. This means non-that user cannot access another users service, even with access to the unix socket(s). For more information, see unix socket authentication security.
- If the MariaDB version was upgraded, the upgrade changes are made automatically.
- `LimitData` places a hard upper limit so the user doesn't exceed a portion of the server resources.

```
# cat /etc/systemd/system/mariadb@.service.d/user.conf
[Service]
User=%I
ProtectHome=false

Environment=MYSQLD_MULTI_INSTANCE="--defaults-file=/home/%I/.my.cnf"

ExecStartPre=
ExecStartPre=/bin/sh -c "[ -f /home/%I/.my.cnf ] || sed -e \"s/USER/%I/g\" /etc/my.cnf.templ >
/home/%I/.my.cnf"
ExecStartPre=mkdir -p /home/%I/mariadb-datadir
ExecStartPre=/usr/bin/mariadb-install-db $MYSQLD_MULTI_INSTANCE --rpm \
   --auth-root-authentication-method=socket --auth-root-socket-user=%I
ExecStartPost=/usr/bin/mariadb-upgrade $MYSQLD_MULTI_INSTANCE

# To limit user based tuning
LimitData=768M
# For io_uring use by innodb on < 5.12 kernels
LimitMEMLOCK=1M
```

Custom Configuration for the Multi-Instance Socket

This extends/modifies the MariaDB socket definition to be per user.

Create sockets based on the user of the instance (`%I`). Permissions are only necessary in the sense that the user can connect to them. It won't matter to the server. Access control is enforced within the server, however if the user web services are run as the user, `Mode=777` can be reduced. `@mariadb-%I` is a abstract unix socket not on the filesystem. It may help if a user is in a chroot. Not all applications can connect to abstract sockets.

```
# cat /etc/systemd/system/mariadb@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenSteam=
ListenStream=@mariadb-%I
ListenStream=/home/%I/mariadb.sock
```

The extra socket provides the user the ability to access the server when all max-connections are used:

```
# cat /etc/systemd/system/mariadb-extra@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenSteam=
ListenStream=@mariadb-extra-%I
ListenStream=/home/%I/mariadb-extra.sock
```

Converting mariadbd-safe Options to Systemd Options

`mariadb-service-convert` is a script included in many MariaDB packages that is used by the package manager to convert mariadbd-safe options to `systemd` options. It reads any explicit settings in the `[mariadbd-safe]` option group from option files, and its output is directed to `/etc/systemd/system/mariadb.service.d/migrated-from-my.cnf-settings.conf`. This helps to keep the configuration the same when upgrading from a version of MariaDB that does not use `systemd` to one that does.

Implicitly high defaults of open-files-limit may be missed by the conversion script and require explicit configuration. See Configuring the Open Files Limit.

sysVinit

sysVinit is one of the most common service managers. On systems that use sysVinit, the mysql.server script is normally installed to `/etc/init.d/mysql`.

Interacting with the MariaDB Server Process

The service can be interacted with by using the service command.

Starting the MariaDB Server Process on Boot

On RHEL/CentOS and other similar distributions, the chkconfig command can be used to enable the MariaDB Server process at boot:

```
chkconfig --add mysql
chkconfig --level 345 mysql on
```

On Debian and Ubuntu and other similar distributions, the update-rc.d command can be used:

```
update-rc.d mysql defaults
```

Starting the MariaDB Server Process

```
service mysql start
```

Stopping the MariaDB Server Process

```
service mysql stop
```

Restarting the MariaDB Server Process

```
service mysql restart
```

Checking the Status of the MariaDB Server Process

```
service mysql status
```

Manually Installing mysql.server with SysVinit

If you install MariaDB from source or from a binary tarball that does not install mysql.server automatically, and if you are on a system that uses sysVinit, then you can manually install `mysql.server` with sysVinit. See mysql.server: Manually Installing with SysVinit for more information.

SysVinit and Galera Cluster

Bootstrapping a New Cluster

When using Galera Cluster with sysVinit, the first node in a cluster has to be started with `service mysql bootstrap`. See Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster for more information.

This page is licensed: CC BY-SA / Gnu FDL

mariadbd-safe

The `mariadbd-safe` startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that starts `mariadbd` with some extra safety features. For example, if `mariadbd-safe` notices that `mariadbd` has crashed, then `mariadbd-safe` automatically restarts `mariadbd`.

`mariadbd-safe` is the recommended way to start `mariadbd` on Linux and Unix distributions that do not support systemd. Additionally, the mysql.server init script used by sysVinit starts `mariadbd` with `mariadbd-safe` by default.

> **Note:**
>
> Previously, the client used to be called `mysqld_safe`, and can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Using mariadbd-safe

The command to use `mariadbd-safe` and the general syntax is:

```
mariadbd-safe [ --no-defaults | --defaults-file | --defaults-extra-file | --defaults-group-suffix | --
print-defaults ] <options> <mariadbd_options>
```

Options

Many of the options supported by `mariadbd-safe` are identical to options supported by mariadbd. If an unknown option is provided to `mariadbd-safe` on the command-line, then it is passed to `mariadbd`.

`mariadbd-safe` supports the following options:

Option	Description
–help	Display a help message and exit.
–autoclose	(NetWare only) On NetWare, mariadbd-safe provides a screen presence. When you unload (shut down) the mariadbd-safe NLM, the screen does not by default go away. Instead, it prompts for user input: NLM has terminated; Press any key to close the screen. If you want NetWare to close the screen automatically instead, use the –autoclose option to mariadbd-safe.
–basedir=path	The path to the MariaDB installation directory.
–core-file-size=size	The size of the core file that mariadbd should be able to create. The option value is passed to ulimit -c.
–crash-script=file	Script to call in the event of mariadbd crashing.
–datadir=path	The path to the data directory.
–defaults-extra-file=path	The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.
–defaults-file=file_name	The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

Option	Description
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.
–flush-caches	Flush and purge buffers/caches before starting the server.
–ledir=path	If mariadbd-safe cannot find the server, use this option to indicate the path name to the directory where the server is located.
–log-error=file_name	Write the error log to the given file.
–malloc-lib=lib	Preload shared library lib if available. See debugging MariaDB for an example.
–mysqld=prog_nam	The name of the server program (in the ledir directory) that you want to start. This option is needed if you use the MariaDB binary distribution but have the data directory outside of the binary distribution. If mariadbd-safe cannot find the server, use the –ledir option to indicate the path name to the directory where the server is located.
–mysqld-version=suffix	This option is similar to the –mysqld option, but you specify only the suffix for the server program name. The basename is assumed to be mysqld. For example, if you use–mysqld-version=debug, mariadbd-safe starts the mariadbd-debug program in the ledir directory. If the argument to –mysqld-version is empty, mariadbd-safe uses mysqld in the ledir directory.
–nice=priority	Use the nice program to set the server´s scheduling priority to the given value.
–no-defaults	Do not read any option files. This must be the first option on the command line if it is used.
–no-watch, –nowatch, –no-auto-restart	Exit after starting mariadbd.
–numa-interleave	Run mariadbd with its memory interleaved on all NUMA nodes.
–open-files-limit=count	The number of files that mariadbd should be able to open. The option value is passed to ulimit -n. Note that you need to start mariadbd-safe as root for this to work properly.
–pid-file=file_name	The path name of the process ID file.
–plugin-dir=dir_name	Directory for client-side plugins.
–port=port_num	The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the root system user.
–print-defaults	Print the program argument list and exit.
–skip-kill-mysqld	Do not try to kill stray mariadbd processes at startup. This option works only on Linux.
–socket=path	The Unix socket file that the server should use when listening for local connections.
–syslog, –skip-syslog	–syslog causes error messages to be sent to syslog on systems that support the logger program. –skip-syslog suppresses the use of syslog; messages are written to an error log file.
–syslog-tag=tag	For logging to syslog, messages from mariadbd-safe and mariadbd are written with a tag of mariadbd-safe and mariadbd, respectively. To specify a suffix for the tag, use –syslog-tag=tag, which modifies the tags to be mariadbd-safe-tag and mariadbd-tag.
–timezone=timezone	Set the TZ time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats. Also see Time Zones.
–user={user_name or user_id}	Run the mariadbd server as the user having the name user_name or the numeric user ID user_id. (“User” in this context refers to a system login account, not a MariaDB user listed in the grant tables.)

Option Files

In addition to reading options from the command-line, `mariadbd-safe` can also read options from option files. If an unknown option is provided to `mariadbd-safe` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the **first argument** on the command-line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadbd-safe` reads options from the following option groups from option files:

Group	Description
[mysqld_safe]	Options read by mysqld_safe, which includes both MariaDB Server and MySQL Server.
[safe_mysqld]	Options read by mysqld_safe, which includes both MariaDB Server and MySQL Server.
[mariadbd-safe]	Options read by mariadbd_safe_safe from MariaDB Server. Available starting with MariaDB 10.4.6.
[mariadb-safe]	Options read by mysqld_safe from MariaDB Server. Deprecated, please avoid using this.

The `[safe_mariadbd]` option group is primarily supported for backward compatibility. You should rename such option groups to `[mariadbd-safe]` in MariaDB installations to prevent breakage in the future if this compatibility is removed.

`mariadbd-safe` also reads options from the following server option groups from option files:

Group	Description
[mysqld]	Options read by mysqld, which includes both MariaDB Server and MySQL Server.
[server]	Options read by MariaDB Server.
[mysqld-X.Y]	Options read by a specific version of mysqld, which includes both MariaDB Server and MySQL Server. For example, [mysqld-5.5].
[mariadb]	Options read by MariaDB Server.
[mariadb-X.Y]	Options read by a specific version of MariaDB Server.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[galera]	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

For example, if you specify the log_error option in a server option group in an option file, like this:

```
[mariadb]
log_error=error.log
```

Then `mariadbd-safe` also uses this value for its own `--log-error` option:

Configuring the Open Files Limit

When using `mariadbd-safe`, the system's open files limit can be changed by providing the `--open-files-limit` option either on the command-line or in an option file. For example:

```
[mariadbd-safe]
open_files_limit=4294967295
```

The option value is passed to `ulimit -n`. Note that you need to start `mariadbd-safe` as root for this to work properly. However, you can't currently set this to `unlimited`. See MDEV-18410 about that.

When `mariadbd-safe` starts `mariadbd`, it also uses this option to set the value of the open_files_limit system variable for `mariadbd`.

Configuring the Core File Size

When using `mariadbd-safe`, if you would like to enable core dumps, the system's core file size limit can be changed by providing the `--core-file-size` option either on the command-line or in an option file. For example:

```
[mariadbd-safe]
core_file_size=unlimited
```

The option value is passed to `ulimit -c`. Note that you need to start `mariadbd-safe` as root for this to work properly.

Configuring MariaDB to Write the Error Log to Syslog

When using `mariadbd-safe`, if you would like to redirect the error log to the syslog, then that can easily be done by using the `--syslog` option. `mariadbd-safe` redirects two types of log messages to the syslog–its own log messages, and log messages for `mariadbd`.

- `mariadbd-safe` configures its own log messages to go to the `daemon` syslog facility. The log level for these messages is either `notice` or `error`, depending on the specific type of log message. The default tag is `mariadbd-safe`.
- `mariadbd-safe` also configures the log messages for `mariadbd` to go to the `daemon` syslog facility. The log level for these messages is `error`. The default tag is `mariadbd`.

Sometimes it can be helpful to add a suffix to the syslog tag, such as if you are running multiple instances of MariaDB on the same host. To add a suffix to each syslog tag, use the `--syslog-tag` option.

Specifying mariadbd

By default, `mariadbd-safe` tries to start an executable named `mariadbd`.

You can also specify another executable for `mariadbd-safe` to start instead of `mariadbd` by providing the `--mariadbd` or `--mariadbd-version` options either on the command-line or in an option file.

By default, it will look for `mariadbd` in the following locations in the following order:

- `$BASEDIR/libexec/mysqld`
- `$BASEDIR/sbin/mysqld`
- `$BASEDIR/bin/mysqld`
- `$PWD/bin/mysqld`
- `$PWD/libexec/mysqld`
- `$PWD/sbin/mysqld`
- `@libexecdir@/mysql`

Where `$BASEDIR` is set by the `--basedir` option, `$PWD` is the current working directory where `mariadbd-safe` was invoked, and `@libexecdir@` is set at compile-time by the `INSTALL_BINDIR` option for cmake.

You can also specify where the executable is located by providing the `--ledir` option either on the command-line or in an option file.

Specifying datadir

By default, `mariadbd-safe` will look for the `datadir` in the following locations in the following order:

- `$BASEDIR/data/mysql`
- `$BASEDIR/data`
- `$BASEDIR/var/mysql`
- `$BASEDIR/var`
- `@localstatedir@`

Where `$BASEDIR` is set by the `--basedir` option, and `@localstatedir@` is set at compile-time by the `INSTALL_MYSQLDATADIR` option for cmake.

You can also specify where the `datadir` is located by providing the `--datadir` option either on the command-line or in an option file.

Logging

When you use `mariadbd-safe` to start `mariadbd`, `mariadbd-safe` logs to the same destination as `mariadbd`.

`mariadbd-safe` has several log-related options:

- `--syslog`: Write error messages to syslog on systems that support the logger program.
- `--skip-syslog`: Do not write error messages to syslog.
  Messages are written to the default error log file (host_name.err in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=file_name`: Write error messages to the named error file.

If none of these options is provided, then the default is `--skip-syslog`.

If `--syslog` and `--log-error` are both provided, then a warning is issued and `--log-error` takes precedence.

`mariadbd-safe` also writes notices to `stdout` and errors to `stderr`.

Editing mariadbd-safe

`mariadbd-safe` is a `sh` script, so if you need to change its behavior, then it can easily be edited. However, you should not normally edit the script. A lot of behavior can be changed by providing options either on the command-line or in an option file.

If you do edit `mariadbd-safe`, then you should be aware of the fact that a package upgrade can overwrite your changes. If you would like to preserve your changes, be sure to have a backup.

NetWare

On NetWare, mariadbd-safe is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on MyISAM tables.
3. Provides a screen presence for the MariaDB server.
4. Starts mariadbd, monitors it, and restarts it if it terminates in error.

5. Sends error messages from mariadbd to the host_name.err file in the data directory.
6. Sends mariadbd-safe screen output to the host_name.safe file in the data directory.

mariadbd-multi

Before using mariadbd-multi be sure that you understand the meanings of the options that are passed to the mariadbd servers and why you would want to have separate mariadbd processes. Beware of the dangers of using multiple mariadbd servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system.

The `mariadbd-multi` startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that is designed to manage several `mariadbd` processes running on the same host.

> **Note:**
>
> Previously, the client was called `mysqld_multi`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

In order for multiple `mariadbd` processes to work on the same host, these processes must:

- Use different Unix socket files for local connections.
- Use different TCP/IP ports for network connections.
- Use different data directories.
- Use different process ID files (specified by the `--pid-file` option) if using mariadbd-safe to start `mariadbd`.

`mariadbd-multi` can start or stop servers, or report their current status.

Using mariadbd-multi

The command to use `mariadbd-multi` and the general syntax is:

```
mariadbd-multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation to perform.

You can specify which servers to perform the operation on by providing one or more `GNR` values. `GNR` refers to an option group number, and it is explained more in the option groups section below. If there is no `GNR` list, then `mariadbd-multi` performs the operation for all `GNR` values found in its option files.

Multiple `GNR` values can be specified as a comma-separated list. `GNR` values can also be specified as a range by separating the numbers by a dash. There must not be any whitespace characters in the `GNR` list.

For example:

This command starts a single server using option group `[mariadbd17]`:

```
mariadbd-multi start 17
```

This command stops several servers, using option groups `[mariadbd8]` and `[mariadbd10]` through `[mariadbd13]`:

```
mariadbd-multi stop 8,10-13
```

Options

`mariadbd-multi` supports the following options:

Option	Description
–example	Give an example of a config file with extra information.
–help	Display help and exit.
–log=filename	Specify the path and name of the log file. If the file exists, log output is appended to it.
–mysqladmin=prog_name	The mariadb-admin binary to be used to stop servers. Can be given within groups [mariadbd#].
–mariadbd=prog_name	The mariadbd binary to be used. Note that you can also specify mariadbd-safe as the value for this option. If you use mariadbd-safe to start the server, you can include the mariadbd or ledir options in the corresponding [mariadbdN] option group. These options indicate the name of the server that mariadbd-safe should start and the path name of the directory where the server is located. Example:\[mariadbd38]mariadbd = mariadbd-debugledir = /opt/local/mysql/libexec.
–no-log	Print to stdout instead of the log file. By default the log file is turned on.
–password=password	The password of the MariaDB account to use when invoking mariadb-admin. Note that the password value is not optional for this option, unlike for other MariaDB programs.
–silent	Silent mode; disable warnings.
–tcp-ip	Connect to the MariaDB server(s) via the TCP/IP port instead of the UNIX socket. This affects stopping and reporting. If a socket file is missing, the server may still be running, but can be accessed only via the TCP/IP port. By default connecting is done via the UNIX socket. This option affects stop and report operations.
–user=username	The user name of the MariaDB account to use when invoking mariadb-admin.
–verbose	Be more verbose.
–version	Display version information and exit.
–wsrep-new-cluster	Bootstrap a cluster. Added in MariaDB 10.1.15.

Option Files

In addition to reading options from the command-line, `mariadbd-multi` can also read options from option files. If an unknown option is provided to `mariadbd-multi` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.

Option	Description
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.
–defaults-group-suffix=#	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadbd-multi` reads options from the following option groups from option files:

Group	Description
[mysqld_multi]	Options read by mysqld_multi, which includes both MariaDB Server and MySQL Server.

`mariadbd-multi` also searches option files for option groups with names like `[mariadbdN]`, where `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or `GNR`:

Group	Description
[mysqld N]	Options read by a mysqld instance managed by mysqld_multi, which includes both MariaDB Server and MySQL Server. The N refers to the instance's GNR.

`GNR` values distinguish option groups from one another and are used as arguments to `mariadbd-multi` to specify which servers you want to start, stop, or obtain a status report for. The `GNR` value should be the number at the end of the option group name in the option file. For example, the `GNR` for an option group named `[mariadbd17]` is `17`.

Options listed in these option groups are the same that you would use in the regular server option groups used for configuring `mariadbd`. However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number.

The `[mariadbd-multi]` option group can be used for options that are needed for `mariadbd-multi` itself. `[mariadbdN]` option groups can be used for options passed to specific `mariadbd` instances.

The regular server option groups can also be used for common options that are read by all instances:

Group	Description
[mysqld]	Options read by mysqld, which includes both MariaDB Server and MySQL Server.
[server]	Options read by MariaDB Server.
[mysqld-X.Y]	Options read by a specific version of mysqld, which includes both MariaDB Server and MySQL Server. For example, [mysqld-5.5].
[mariadb]	Options read by MariaDB Server.
[mariadb-X.Y]	Options read by a specific version of MariaDB Server.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[galera]	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

For an example of how you might set up an option file, use this command:

```
mariadbd-multi --example
```

Authentication and Privileges

Make sure that the MariaDB account used for stopping the `mariadbd` processes (with the mariadb-admin utility) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you

might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
 -> TO ´multi_admin´@´localhost´ IDENTIFIED BY ´multipass´;
```

Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must allow you to connect as `multi_admin` from the host where you want to run `mariadbd-multi`.

User Account

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mariadbd` process is started as. If you run the `mariadbd-multi` script as the Unix `root` account, and if you want the `mariadbd` process to be started with another Unix account, then you can use the `--user` option with `mariadbd`. If you specify the `--user` option in an option file, and if you did not run the `mariadbd-multi` script as the Unix `root` account, then it will just log a warning and the `mariadbd` processes are started under the original Unix account.

Do not run the `mariadbd` process as the Unix `root` account, unless you know what you are doing.

Example

The following example shows how you might set up an option file for use with mariadbd-multi. The order in which the mariadbd programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [mariadbdN] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
           # or /etc/my.cnf
           # Version 2.1 by Jani Tolonen
           [mariadbd-multi]
           mariadbd     = /usr/local/bin/mariadbd-safe
           mysqladmin = /usr/local/bin/mysqladmin
           user       = multi_admin
           password   = multipass
           [mariadbd2]
           socket     = /tmp/mysql.sock2
           port       = 3307
           pid-file   = /usr/local/mysql/var2/hostname.pid2
           datadir    = /usr/local/mysql/var2

mariadbd Options

This page lists all of the options for `mariadbd` (called mysqld before MariaDB 10.5), ordered by topic. For a full alphabetical list of all mariadbd options, as well as server and status variables, see Full list of MariaDB options, system and status variables.

In many cases, the entry here is a summary, and links to the full description.

By convention, server variables have usually been specified with an underscore in the configuration files, and a dash on the command line. You can however specify underscores as dashes - they are interchangeable.

See Configuring MariaDB with Option Files for which files and groups mariadbd reads for it's default options.

> **Note:**
>
> Previously, the client used to be called `mysqld`, and can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

Option Prefixes

`--autoset-*`

- Description: Sets the option value automatically. Only supported for certain options.

`--disable-*`

- Description: For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `--skip`.

`--enable-*`

- Description: For all boolean options, enables the setting (equivalent to setting it to `1`).

`--loose-*`

- Description: Don't produce an error if the option doesn't exist.

`--maximum-*`

- Description: Sets the maximum value for the option.

`--skip-*`

- Description: For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `--disable`.

Option File Options

`--defaults-extra-file`

- Command line: `--defaults-extra-file=name`
- Description: Read this extra option file after all other option files are read.
  - See Configuring MariaDB with Option Files.

`--defaults-file`

- Command line: `--defaults-file=name`
- Description: Only read options from the given option file.
  - See Configuring MariaDB with Option Files.

`--defaults-group-suffix`

- Command line: `--defaults-group-suffix=name`
- Description: In addition to the default option groups, also read option groups with the given suffix.
  - See Configuring MariaDB with Option Files.

`--no-defaults`

- Command line: `--no-defaults`
- Description: Don't read options from any option file.
  - See Configuring MariaDB with Option Files.

`--print-defaults`

- Command line: `--print-defaults`
- Description: Read options from option files, print all option values, and then exit the program.
  - See Configuring MariaDB with Option Files.

Compatibility Options

The following options have been added to MariaDB to make it more compliant with other MariaDB and MySQL versions. Options that are also system variables are listed after:

`-a, --ansi`

- Description: Use ANSI SQL syntax instead of MariaDB syntax. This mode will also set transaction isolation level serializable.

`--new`

- Description: Use new functionality that will exist in next version of MariaDB. This function exists to make it easier to prepare for an upgrade.

`--old-style-user-limits`

- Description: Enable old-style user limits (before MySQL 5.0.3, user resources were counted per each user+host vs. per account).

`--safe-mode`

- Description: Disable some potential unsafe optimizations. For 5.2, INSERT DELAYED is disabled, myisam_recover_options is set to DEFAULT (automatically recover crashed MyISAM files) and the query cache is disabled. For Aria tables, disable bulk insert optimization to enable one to use aria_read_log to recover tables even if tables are deleted (good for testing recovery).

`--skip-new`

- Description: Disables –new.

Compatibility Options and System Variables

- –new-mode
- –old
- –old-alter-table
- –old-mode
- –old-passwords
- –show-old-temporals

Locale Options

Options that are also system variables are listed after:

`--character-set-client-handshake`

- Command line: `--character-set-client-handshake`
- Description: Don't ignore client side character set value sent during handshake. `--skip-character-set-client-handshake` will ignore the client value and use the default server value.

`--default-character-set`

- Command line: `--default-character-set=name`
- Description: Still available as an option for setting the default character set for clients and their connections, it was deprecated and removed in MariaDB 10.2 as a server option. Use character-set-server instead.

`--language`

- Description: This option can be used to set the server's language for error messages. This option can be specified either as a language name or as the path to the directory storing the language's error message file. See Server Locales for a list of supported locales and their associated languages.
  - This option is deprecated. Use the lc_messages and lc_messages_dir system variables instead.

- See Setting the Language for Error Messages for more information.

Locale Options and System Variables

- character-set-filesystem
- character-set-client
- character-set-connection
- character-set-database
- character-set-filesystem
- character-set-results
- character-set-server
- character-set-system
- character-sets-dir
- collation-connection
- collation-database
- collation-server
- default-week-format
- default-time-zone
- lc-messages
- lc-messages-dir
- lc-time-names

Windows Options

Options that are also system variables are listed after:

`--console`

- Description: Windows-only option that keeps the console window open and for writing log messages to stderr and stdout. If specified together with –log-error, the last option will take precedence.

`--install`

- Description: Windows-only option that installs the `mariadbd` process as a Windows service.
  - The Windows service created with this option auto-starts. If you want a service that is started on demand, then use the –install-manual option.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to “MARIADB”.
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--install-manual`

- Description: Windows-only option that installs the `mariadbd` process as a Windows service.
  - The Windows service created with this option is started on demand. If you want a service that auto-starts, use the –install option.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to “MARIADB”.
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--remove`

- Description: Windows-only option that removes the Windows service created by the –install or –install-manual options.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to “MARIADB”.
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--slow-start-timeout`

- Description: Windows-only option that defines the maximum number of milliseconds that the service control manager should wait before trying to kill the Windows service during startup. Defaults to `15000`.

`--standalone`

- Description: Windows-only option that has no effect. Kept for compatibility reasons.

Windows Options and System Variables

The following options and system variables are related to using MariaDB on Windows:

- –named-pipe

Replication and Binary Logging Options

The following options are related to replication and the binary log. Options that are also system variables are listed after:

`--abort-slave-event-count`

- Command line: `--abort-slave-event-count=#`
- Description: Option used by mysql-test for debugging and testing of replication.

`--binlog-do-db`

- Command line: `--binlog-do-db=name`
- Description: This option allows you to configure a replication master to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - This option can not be set dynamically. Available as a system variable from MariaDB 11.2.0.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.

`--binlog-ignore-db`

- Command line: `--binlog-ignore-db=name`
- Description: This option allows you to configure a replication master to not write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will not work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - This option can not be set dynamically. Available as a system variable from MariaDB 11.2.0.

    - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
    - See Replication Filters for more information.

`--binlog-row-event-max-size`

- Command line: `--binlog-row-event-max-size=#`
- Description: The maximum size of a row-based binary log event in bytes. Rows will be grouped into events smaller than this size if possible. The value has to be a multiple of 256. Available as a system variable from MariaDB 11.2.0.
- Default value `8192`

`--disconnect-slave-event-count`

- Command line: `--disconnect-slave-event-count=#`
- Description: Option used by mysql-test for debugging and testing of replication.

`--flashback`

- Command line: `--flashback`
- Description: Setup the server to use flashback. This enables the binary log and sets `binlog_format=ROW`.

`--log-basename`

- Command line: `--log-basename=name`
- Description: Basename for all log files and the .pid file. This sets all log file names at once (in 'datadir') and is normally the only option you need for specifying log files. This is especially recommended to be set if you are using replication as it ensures that your log file names are not dependent on your host name. Sets names for the binary log, relay log, general query log, slow query log and error log. Note that if you explicitly set log file names with any of these other options; log-bin-index, relay-log, relay-log-index, general-log-file, log_slow_query_file (slow_query_log_file), log_error, and pid-file, these should be placed after `--log-basename` in the config files. Later settings override earlier settings, so `log-basename` will override any earlier log file name settings.

`--log-bin-trust-routine-creators`

- Command line: `--log-bin-trust-routine-creators`
- Description: Deprecated, use log-bin-trust-function-creators.

`--master-host`

- Command line: `--master-host=name`
- Description: Primary hostname or IP address for replication. If not set, the replica thread will not be started. Note that the setting of master-host will be ignored if there exists a valid master.info file.

`--master-info-file`

- Command line: `--master-info-file=name`
- Description: Name and location of the file on the replica where the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options (i.e. the binary log position on the primary) and most other CHANGE MASTER options are written. The replica's I/O thread keeps this binary log position updated as it downloads events.
    - See CHANGE MASTER TO: Option Persistence for more information.

`--master-password`

- Command line: `--master-password=name`
- Description: The password the replica thread will authenticate with when connecting to the primary. If not set, an empty password is assumed. The value in master.info will take precedence if it can be read.

`--master-port`

- Command line: `--master-port=#`
- Description: The port the master is listening on. If not set, the compiled setting of MYSQL_PORT is assumed. If you have not tinkered with configure options, this should be 3306. The value in master.info will take precedence if it can be read.

`--master-retry-count`

- Command line: `--master-retry-count=#`
- Description: Number of times a replica will attempt to connect to a primary before giving up. The retry interval is determined by the MASTER_CONNECT_RETRY option for the CHANGE MASTER statement. A value of 0 means the replica will not stop attempting to reconnect. Reconnects are triggered when a replica has timed out. See slave_net_timeout.
- Default Value: `86400` through 10.5, `100000` as of 10.6
- Range - 32 bit: `0 to 4294967295`
- Range - 64 bit: `0 to 18446744073709551615`

`--master-ssl`

- Command line: `--master-ssl`
- Description: Enable the replica to connect to the master using TLS.

`--master-ssl-ca`

- Command line: `--master-ssl-ca[=name]`
- Description: Master TLS CA file. Only applies if you have enabled master-ssl.

`--master-ssl-capath`

- Command line: `--master-ssl-capath[=name]`
- Description: Master TLS CA path. Only applies if you have enabled master-ssl.

`--master-ssl-cert`

- Command line: `--master-ssl-cert[=name]`
- Description: Master TLS certificate file name. Only applies if you have enabled master-ssl.

`--master-ssl-cipher`

- Command line: `--master-ssl-cipher[=name]`
- Description: Master TLS cipher. Only applies if you have enabled master-ssl.

`--master-ssl-key`

- Command line: `--master-ssl-key[=name]`
- Description: Master TLS keyfile name. Only applies if you have enabled master-ssl.

`--master-user`

- Command line: `--master-user=name`
- Description: The username the replica thread will use for authentication when connecting to the primary. The user must have FILE privilege. If the primary user is not set, user test is assumed. The value in master.info will take precedence if it can be read.

`--max-binlog-dump-events`

- Command line: `--max-binlog-dump-events=#`
- Description: Option used by mysql-test for debugging and testing of replication.

`--replicate-same-server-id`

- Command line: `--replicate-same-server-id`
- Description: In replication, if set to 1, do not skip events having our server id. Default value is 0 (to break infinite loops in circular replication). Can't be set to 1 if log-slave-updates is used. Added as a system variable in MariaDB 12.0.

`--sporadic-binlog-dump-fail`

- Command line: `--sporadic-binlog-dump-fail`
- Description: Option used by mysql-test for debugging and testing of replication.

`--sysdate-is-now`

- Command line: `--sysdate-is-now`
- Description: Non-default option to alias SYSDATE() to NOW() to make it safe for replication. Since 5.0, SYSDATE() has returned a `dynamic' value different for different invocations, even within the same statement.

Replication and Binary Logging Options and System Variables

The options and system variables related to Replication and Binary Logging are described on Replication and Binary Logging System Variables.

Semisynchronous Replication Options and System Variables

The options and system variables related to Semisynchronous Replication are described here.

Optimizer Options

Options that are also system variables are listed after:

`--record-buffer`

- Command line: `--record-buffer=#`
- Description: Old alias for read_buffer_size.
- Removed: MariaDB 5.5

`--table-cache`

- Command line: `--table-open-cache=#`
- Description: Removed; use –table-open-cache instead.
- Removed: MariaDB 5.3.1

Optimizer Options and System Variables

- alter-algorithm
- analyze-max-length
- analyze-sample-percentage
- big-tables
- bulk-insert-buffer-size
- expensive-subquery-limit
- join-buffer-size
- join-buffer-space-limit
- join-cache-level
- max-heap-table-size
- max-join-size
- max-seeks-for-key
- max-sort-length
- mrr-buffer-size
- optimizer-adjust-secondary-key-costs
- optimizer-extra-pruning-depth
- optimizer-join-limit-pref-ratio
- optimizer-max-sel-arg-weight
- optimizer-max-sel-args
- optimizer-prune-level
- optimizer-record-context
- optimizer-search-depth
- optimizer-selectivity-sampling-limit
- optimizer-switch
- optimizer-trace
- optimizer-trace-max-mem-size
- optimizer-use-condition-selectivity
- query-alloc-block-size
- query-prealloc-size
- range-alloc-block-size
- read-buffer-size

- table-open-cache
- table-open-cache-instances
- tmp-disk-table-size
- tmp-memory-table-size
- tmp-table-size
- use-stat-tables

Storage Engine Options

`--skip-bdb`

- Command line: `----skip-bdb`

- Description: Deprecated option; Exists only for compatibility with very old my.cnf files.
- Removed: MariaDB 10.5.1

`--external-locking`

- Command line: `--external-locking`
- Description: Use system (external) locking (disabled by default). With this option enabled you can run myisamchk to test (not repair) tables while the server is running. Disable with –skip-external-locking. From MariaDB 10.2.40, MariaDB 10.3.31, MariaDB 10.4.21, MariaDB 10.5.12, MariaDB 10.6.4 and all later version, this effects InnoDB and can be used to prevent multiple instances running on the same data.

MyISAM Storage Engine Options

The options related to the MyISAM storage engine are described below. Options that are also system variables are listed after:

`--log-isam`

- Command line: `--log-isam[=file_name]`
- Description: Enable the MyISAM log, which logs all MyISAM changes to file. If no filename is provided, the default, myisam.log is used.

MyISAM Storage Engine Options and System Variables

Some options and system variables related to the MyISAM storage engine can be found here. Direct links to many of them can be found below.

- concurrent-insert
- delayed-insert-limit
- delayed-insert-timeout
- delayed-queue-size
- keep-files-on-create
- key-buffer-size
- key-cache-age-threshold
- key-cache-block-size
- key-cache-division-limit
- key-cache-file-hash-size
- key-cache-segments
- myisam-block-size
- myisam-data-pointer-size
- myisam-max-sort-file-size
- myisam-mmap-size
- myisam-recover-options
- myisam-repair-threads
- myisam-sort-buffer-size
- myisam-stats-method
- myisam-use-mmap

InnoDB Storage Engine Options

The options related to the InnoDB storage engine are described below. Options that are also system variables are listed after:

`--innodb`

- Command line: `--innodb=value`, `--skip-innodb`
- Description: This variable controls whether or not to load the InnoDB storage engine. Possible values are `ON`, `OFF`, `FORCE` or `FORCE_PLUS_PERMANENT` (from MariaDB 5.5). If set to `OFF` (the same as –skip-innodb), since InnoDB is the default storage engine, the server will not start unless another storage engine has been chosen with –default-storage-engine. `FORCE` means that the storage engine must be successfully loaded, or else the server won't start. `FORCE_PLUS_PERMANENT` enables the plugin, but if plugin cannot initialize, the server will not start. In addition, the plugin cannot be uninstalled while the server is running.

`--innodb-cmp`

- Command line: `--innodb-cmp`
- Description:
- Default: `ON`

`--innodb-cmp-reset`

- Command line: `--innodb-cmp-reset`
- Description:
- Default: `ON`

`--innodb-cmpmem`

- Command line: `--innodb-cmpmem`
- Description:
- Default: `ON`

`--innodb-cmpmem-reset`

- Command line: `--innodb-cmpmem-reset`
- Description:
- Default: `ON`

`--innodb-file-io-threads`

- Command line: `--innodb-file-io-threads`
- Description:
- Default: `4`
- Removed: MariaDB 10.3.0

`--innodb-index-stats`

- Command line: `--innodb-index-stats`
- Description:
- Default: `ON`
- Removed: MariaDB 10.0.0

`--innodb-lock-waits`

- Command line: `--innodb-lock-waits`
- Description:
- Default: `ON`

`--innodb-locks`

- Command line: `--innodb-locks`
- Description:
- Default: `ON`

`--innodb-rseg`

- Command line: `--innodb-rseg`
- Description:
- Default: `ON`
- Removed: MariaDB 10.0.0

`--innodb-status-file`

- Command line: `--innodb-status-file`
- Description:
- Default: `FALSE`

`--innodb-sys-indexes`

- Command line: `--innodb-sys-indexes`
- Description:
- Default: `ON`

`--innodb-sys-stats`

- Command line: `--innodb-sys-stats`
- Description:
- Default: `ON`
- Removed: MariaDB 10.0.0

`--innodb-sys-tables`

- Command line: `--innodb-sys-tables`
- Description:
- Default: `ON`

`--innodb-table-stats`

- Command line: `--innodb-table-stats`
- Description:
- Default: `ON`
- Removed: MariaDB 10.0.0

`--innodb-trx`

- Command line: `--innodb-trx`
- Description:
- Default: `ON`

Spider Storage Engine Options

The options and system variables related to the Spider storage engine can be found here.

Mroonga Storage Engine Options

The options and system variables related to the Mroonga storage engine can be found here.

Vector Options

The options and system variables related to Vectors storage engine (beginning with `mhnsw`) can be found here.

Performance Schema Options

The options related to the Performance Schema are described below. Options that are also system variables are listed after:

`--performance-schema-consumer-events-stages-current`

- Command line: `--performance-schema-consumer-events-stages-current`
- Description: Enable the events-stages-current consumer.
- Default: `OFF`

`--performance-schema-consumer-events-stages-history`

- Command line: `--performance-schema-consumer-events-stages-history`
- Description: Enable the events-stages-history consumer.
- Default: `OFF`

`--performance-schema-consumer-events-stages-history-long`

- Command line: `--performance-schema-consumer-events-stages-history-long`
- Description: Enable the events-stages-history-long consumer.
- Default: `OFF`

`--performance-schema-consumer-events-statements-current`

- Command line: `--performance-schema-consumer-events-statements-current`
- Description: Enable the events-statements-current consumer. Use `--skip-performance-schema-consumer-events-statements-current` to disable.
- Default: `ON`

`--performance-schema-consumer-events-statements-history`

- Command line: `--performance-schema-consumer-events-statements-history`
- Description: Enable the events-statements-history consumer.
- Default: `OFF`

`--performance-schema-consumer-events-statements-history-long`

- Command line: `--performance-schema-consumer-events-statements-history-long`
- Description: Enable the events-statements-history-long consumer.
- Default: `OFF`

`--performance-schema-consumer-events-waits-current`

- Command line: `--performance-schema-consumer-events-waits-current`
- Description: Enable the events-waits-current consumer.
- Default: `OFF`

`--performance-schema-consumer-events-waits-history`

- Command line: `--performance-schema-consumer-events-waits-history`
- Description: Enable the events-waits-history consumer.
- Default: `OFF`

`--performance-schema-consumer-events-waits-history-long`

- Command line: `--performance-schema-consumer-events-waits-history-long`
- Description: Enable the events-waits-history-long consumer.
- Default: `OFF`

`--performance-schema-consumer-global-instrumentation`

- Command line: `--performance-schema-consumer-global-instrumentation`
- Description: Enable the global-instrumentation consumer. Use `--skip-performance-schema-consumer-global-instrumentation` to disable.
- Default: `ON`

`--performance-schema-consumer-statements-digest`

- Command line: `--performance-schema-consumer-statements-digest`
- Description: Enable the statements-digest consumer. Use `--skip-performance-schema-consumer-statements-digest` to disable.
- Default: `ON`

`--performance-schema-consumer-thread-instrumentation`

- Command line: `--performance-schema-consumer-thread-instrumentation`
- Description: Enable the statements-thread-instrumentation. Use `--skip-performance-schema-thread-instrumentation` to disable.
- Default: `ON`

Performance Schema Options and System Variables

Some options and system variables related to the Performance Schema can be found here. Direct links to many of them can be found below.

- performance-schema
- performance-schema-accounts-size
- performance-schema-digests-size
- performance-schema-events-stages-history-long-size

Galera Cluster Options

The options related to Galera Cluster are described below. Options that are also system variables are listed after:

`--wsrep-new-cluster`

- Command line: `--wsrep-new-cluster`
- Description: Bootstrap a cluster. It works by overriding the current value of wsrep_cluster_address. It is recommended not to add this option to the config file as this will trigger bootstrap on every server start.

Galera Cluster Options and System Variables

Some options and system variables related to Galera Cluster can be found here. Direct links to many of them can be found below.

- wsrep-allowlist
- wsrep_applier_retry_count
- wsrep-auto-increment-control

Options When Debugging mariadbd

`--debug-assert-if-crashed-table`

- Description: Do an assert in handler::print_error() if we get a crashed table.

`--debug-binlog-fsync-sleep`

- Description: `--debug-binlog-fsync-sleep=#` If not set to zero, sets the number of micro-seconds to sleep after running fsync() on the binary log to flush transactions to disk. This can thus be used to artificially increase the perceived cost of such an fsync().

`--debug-crc-break`

- Description: `--debug-crc-break=#` Call my_debug_put_break_here() if crc matches this number (for debug).

`--debug-flush`

- Description: Default debug log with flush after write.

`--debug-no-sync`

- Description: `debug-no-sync[=#]` Disables system sync calls. Only for running tests or debugging!

`--debug-sync-timeout`

- Description: `debug-sync-timeout[=#]` Enable the debug sync facility and optionally specify a default wait timeout in seconds. A zero value keeps the facility disabled.

`--gdb`

- Description: Set up signals usable for debugging.

`--silent-startup`

- Description: Don't print Notes to the error log during startup.

`--sync-sys`

- Description: Enable/disable system sync calls. Syncs should only be turned off (`--disable-sync-sys`) when running tests or debugging! Replaced by debug-no-sync from MariaDB 5.5.
- Removed: MariaDB 5.5

`--thread-alarm`

- Description: Enable/disable system thread alarm calls. Should only be turned off (`--disable-thread-alarm`) when running tests or debugging!

Debugging Options and System Variables

- core-file
- debug
- debug-no-thread-alarm

Other Options

Options that are also system variables are listed after:

`--allow-suspicious-udfs`

- Command line: `--allow-suspicious-udfs`
- Description: Allows use of user-defined functions consisting of only one symbol `x()` without corresponding `x_init()` or `x_deinit()` . That also means that one can load any function from any library, for example

`exit()` from `libc.so`. Not recommended unless you require old UDFs with one symbol that cannot be recompiled. From MariaDB 10.10, available as a system variable as well.

`--bootstrap`

- Command line: `--bootstrap`
- Description: Used by mariadb installation scripts, such as mariadb-install-db to execute SQL scripts before any privilege or system tables exist. Do no use while an existing MariaDB instance is running.

`--chroot`

- Command line: `--chroot=name`
- Description: Chroot mariadbd daemon during startup.

`--des-key-file`

- Command line: `--des-key-file=name`
- Description: Load keys for des_encrypt() and des_decrypt() from the given file.
- Removed: MariaDB 13.0, together with the `DES_ENCRYPT()` / `DES_DECRYPT()` functions and the `FLUSH DES_KEY_FILE` statement.

`--exit-info`

- Command line: `--exit-info[=#]`
- Description: Used for debugging. Use at your own risk.

`--getopt-prefix-matching`

- Command line: `--getopt-prefix-matching={0|1}`
- Description: Makes it possible to disable historical “unambiguous prefix” matching in the command-line option parsing.
- Default: TRUE
- Introduced: MariaDB 10.1.3

`--help`

- Command line: `--help`
- Description: Displays help with many commandline options described, and exits. From MariaDB 11.5, includes deprecation information.

`--log-ddl-recovery`

- Command line: `--log-ddl-recovery=name`
- Description: Path to file used for recovery of DDL statements after a crash.
- Default Value: `ddl-recover.log`
- Introduced: MariaDB 10.6.1

`--log-short-format`

- Command line: `--log-short-format`
- Description: Don’t log extra information to update and slow-query logs.

`--log-slow-file`

- Command line: `--log-slow-file=name`

- Description: Log slow queries to given log file. Defaults logging to hostname-slow.log

`--log-slow-time`

- Command line: `--log-slow-time=#`
- Description: Log all queries that have taken more than long-query-time seconds to execute to the slow query log, if active. The argument will be treated as a decimal value with microsecond precision.

`--log-tc`

- Command line: `--log-tc=name`
- Description: Defines the path to the memory-mapped file-based transaction coordinator log, which is only used if the binary log is disabled. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available. See Transaction Coordinator Log for more information. Also see the log_tc_size system variable and the –tc-heuristic-recover option.
- Default Value: `tc.log`

`--master-connect-retry`

- Command line: `--master-connect-retry=#`
- Description: Deprecated in 5.1.17 and removed in 5.5. The number of seconds the replica thread will sleep before retrying to connect to the master, in case the master goes down or the connection is lost.

`--memlock`

- Command line: `--memlock`
- Description: Lock mariadbd in memory.

`--ndb-use-copying-alter-table`

- Command line: `--ndb-use-copying-alter-table`
- Description: Force ndbcluster to always copy tables at alter table (should only be used if on-line alter table fails).

`--one-thread`

- Command line: `--one-thread`
- Description: (Deprecated): Only use one thread (for debugging under Linux). Use thread-handling=no-threads instead.
- Removed: MariaDB 10.0.4

`--plugin-load`

- Command line: `--plugin-load=name`
- Description: This option can be used to configure the server to load specific plugins. This option uses the following format:
  - Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
  - Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
  - Multiple plugins can be specified by separating them with semicolons.
- Special care must be taken when specifying the –plugin-load option multiple times, or when specifying both the –plugin-load option and the –plugin-load-add option together. The –plugin-load option resets the plugin load list, and this can cause unexpected problems if you are not aware. The –plugin-load-add option does not reset the

plugin load list, so it is much safer to use. See Plugin Overview: Specifying Multiple Plugin Load Options for more information.

- See Plugin Overview: Installing a Plugin with Plugin Load Options for more information.

`--plugin-load-add`

- Command line: `--plugin-load-add=name`
- Description: This option can be used to configure the server to load specific plugins. This option uses the following format:
  - Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
  - Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
  - Multiple plugins can be specified by separating them with semicolons.
- Special care must be taken when specifying both the –plugin-load option and the –plugin-load-add option together. The –plugin-load option resets the plugin load list, and this can cause unexpected problems if you are not aware. The –plugin-load-add option does not reset the plugin load list, so it is much safer to use. See Plugin Overview: Specifying Multiple Plugin Load Options for more information.
- See Plugin Overview: Installing a Plugin with Plugin Load Options for more information.

`--port-open-timeout`

- Command line: `--port-open-timeout=#`
- Description: Maximum time in seconds to wait for the port to become free. (Default: No wait).

`--safe-user-create`

- Command line: `--safe-user-create`
- Description: Don't allow new user creation by the user who has no write privileges to the mysql.user table.

`--safemalloc-mem-limit`

- Command line: `--safemalloc-mem-limit=#`
- Description: Simulate memory shortage when compiled with the `--with-debug=full` option.

`--show-slave-auth-info`

- Command line: `--show-slave-auth-info`
- Description: Show user and password in SHOW REPLICA HOSTS (SHOW SLAVE HOSTS) on this primary. Also added as a system variable in MariaDB 12.0.

`--skip-grant-tables`

- Command line: `--skip-grant-tables`
- Description: Start without grant tables. This gives all users FULL ACCESS to all tables, which is useful in case of a lost root password. Use mariadb-admin flush-privileges, mariadb-admin reload or FLUSH PRIVILEGES to resume using the grant tables. From MariaDB 10.10, available as a system variable as well.

Because the Event Scheduler also depends on the grant tables for its functionality, it is automatically disabled when running with `--skip-grant-tables`.

`--skip-host-cache`

- Command line: `--skip-host-cache`

- Description: Don't cache host names.

`--skip-partition`

- Command line: `--skip-partition`, `--disable-partition`
- Description: Disables user-defined partitioning. Previously partitioned tables cannot be accessed or modified. Tables can still be seen with SHOW TABLES or by viewing the INFORMATION_SCHEMA.TABLES table. Tables can be dropped with DROP TABLE, but this only removes .frm files, not the associated .par files, which will need to be removed manually.

`--skip-slave-start`

- Command line: `--skip-slave-start`
- Description: If set, replica is not autostarted. From MariaDB 12.0, server will display in the log if this option is set.

`--skip-ssl`

- Command line: `--skip-ssl`
- Description: Disable TLS connections.

`--skip-symlink`

- Command line: `--skip-symlink`
- Description: Don't allow symlinking of tables. Deprecated and removed in MariaDB 5.5. Use symbolic-links with the `skip` option prefix instead.
- Removed: MariaDB 5.5

`--skip-thread-priority`

- Command line: `--skip-thread-priority`
- Description: Don't give threads different priorities. Deprecated and removed in MariaDB 10.0.
- Removed: MariaDB 10.0

`--sql-bin-update-same`

- Command line: `--sql-bin-update-same=#`
- Description: The update log was deprecated in version 5.0 and replaced by the binary log, so this option did nothing since then. Deprecated and removed in MariaDB 5.5.
- Removed: MariaDB 5.5

`--ssl`

- Command line: `--ssl`
- Description: Enable TLS for connection (automatically enabled with other flags). Disable with '`--skip-ssl`'.

`--stack-trace`

- Command line: `--stack-trace`, `--skip-stack-trace`
- Description: Print a stack trace on failure. Enabled by default, disable with `-skip-stack-trace`.

`--symbolic-links`

- Command line: `--symbolic-links`
- Description: Enables symbolic link support. When set, the have_symlink system variable shows as `YES`. Silently ignored in Windows. Use `--skip-symbolic-links` to disable.

`--tc-heuristic-recover`

- Command line: `--tc-heuristic-recover=name`
- Description: If manual heuristic recovery is needed, this option defines the decision to use in the heuristic recovery process. Manual heuristic recovery may be needed if the transaction coordination log is missing or if it doesn't contain all prepared transactions. This option can be set to `OFF`, `COMMIT`, or `ROLLBACK`. The default is `OFF`. See also the –log-tc server option and the log_tc_size system variable.

`--temp-pool`

- Command line: `--temp-pool`
- Description: Using this option will cause most temporary files created to use a small set of names, rather than a unique name for each new file. This behavior works around a bug in old Linux kernels where the kernel appeared to "leak" memory. In a Docker environment it might look like an unbounded working-set memory growth.
  Defaults to `1` until MariaDB 10.5.6, use `--skip-temp-pool` to disable. Defaults to `0` from MariaDB 10.5.7, as benchmarking shows it causes a heavy mutex contention.

`--test-expect-abort`

- Command line: `--test-expect-abort`
- Description: Expect that server aborts with 'abort'; Don't write out server variables on 'abort'. Useful only for test scripts.

`--test-ignore-wrong-options`

- Command line: `--test-ignore-wrong-options`
- Description: Ignore wrong enums values in command line arguments. Useful only for test scripts.

`--user`

- Command line: `--user=name`
- Description: Run mariadbd daemon as user.

`--verbose`

- Command line: `-v`, `--verbose`
- Description: Used with help option for detailed help.

Replication Plugin - `rpl_semi_sync_slave`

The system variables related to the rpl_semi_sync_slave replication plugin can be found here.

The options related to the rpl_semi_sync_slave replication plugin can be found here.

Default Values

You can verify the default values for an option by doing:

```
mariadbd --no-defaults --help --verbose
```

This page is licensed: GPLv2

mariadbd

> **Note:**
>
> Previously, the client was called `mysqld`. It can still be accessed under this name, via a symlink in Linux, or an alternate binary in Windows.

See mariadbd-options for details.

This page is licensed: CC BY-SA / Gnu FDL

mysql.server

The mysql.server startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that works as a standard sysVinit script. However, it can be used independently of sysVinit as a regular `sh` script. The script starts the mariadbd server process by first changing its current working directory to the MariaDB install directory and then starting mariadbd-safe. The script requires the standard sysVinit arguments, such as `start`, `stop`, `restart`, and `status`. For example:

```
mysql.server start
mysql.server restart
mysql.server stop
mysql.server status
```

It can be used on systems such as Linux, Solaris, and Mac OS X.

The `mysql.server` script starts mariadbd by first changing to the MariaDB install directory and then calling mariadbd-safe.

Using mysql.server

The command to use `mysql.server` and the general syntax is:

```
mysql.server [ start | stop | restart | status ] <options> <mariadbd_options>
```

Options

If an unknown option is provided to `mariadbd-safe` on the command-line, it is passed to `mariadbd-safe`.

`mysql.server` supports the following options:

Option	Description
–basedir=path	The path to the MariaDB installation directory.
–datadir=path	The path to the MariaDB data directory.
–pid-file=file_name	The path name of the file in which the server should write its process ID. If not provided, the default, host_name.pid is used.
–service-startup-timeout=file_name	How long in seconds to wait for confirmation of server startup. If the server does not start within this time, mysql.server exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).
–use-mysqld_safe	Use mariadbd-safe to start the server. This is the default.
–use-manager	Use Instance Manager to start the server.
–user=user_name	The login user name to use for running mariadbd.

Option Files

In addition to reading options from the command-line, `mysql.server` can also read options from option files.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
–print-defaults	Print the program argument list and exit.
–no-defaults	Don't read default options from any option file.
–defaults-file=#	Only read default options from the given file #.
–defaults-extra-file=#	Read this file after the global files are read.

Option Groups

`mysql.server` reads options from the following option groups from option files:

Group	Description
[mysql.server]	Options read by mysql.server, which includes both MariaDB Server and MySQL Server.

`mysql.server` also reads options from the following server option groups from option files:

Group	Description
[mysqld]	Options read by mysqld, which includes both MariaDB Server and MySQL Server.
[server]	Options read by MariaDB Server.
[mysqld-X.Y]	Options read by a specific version of mysqld, which includes both MariaDB Server and MySQL Server. For example, [mysqld-5.5].

Group	Description
[mariadbd]	Options read by MariaDB Server.
[mariadbd-X.Y]	Options read by a specific version of MariaDB Server.
[client-server]	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
[galera]	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

Customizing mysql.server

If you have installed MariaDB to a non-standard location, then you may need to edit the `mysql.server` script to get it to work right.

If you do not want to edit the `mysql.server` script itself, then `mysql.server` also sources a few other `sh` scripts. These files can be used to set any variables that might be needed to make the script work in your specific environment. The files are:

- `/etc/default/mysql`
- `/etc/sysconfig/mysql`
- `/etc/conf.d/mysql`

Installed Locations

`mysql.server` can be found in the `support-files` directory under your MariaDB installation directory or in a MariaDB source distribution.

Installed SysVinit Locations

On systems that use sysVinit, `mysql.server` may also be installed in other locations and with other names.

If you installed MariaDB on Linux using RPMs, the `mysql.server` script is installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually.

Manually Installing with SysVinit

If you install MariaDB from source or from a binary tarball that does not install mysql.server automatically, and if you are on a system that uses sysVinit, then you can manually install `mysql.server` with sysVinit. This is usually done by copying it to `/etc/init.d/` and then creating specially named symlinks in the appropriate `/etc/rcX.d/` directories (where 'X' is a number between 0 and 6).

In the examples below we will follow the historical convention of renaming the `mysql.server` script to '`mysql`' when we copy it to `/etc/init.d/`.

The first step for most Linux distributions is to copy the `mysql.server` script to `/etc/init.d/` and make it executable:

```
cd /path/to/your/mariadb-version/support-files/
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

Now all that is needed is to create the specially-named symlinks. On both RPM and Debian-based Linux distributions there are tools which do this for you. Consult your distribution's documentation if neither of these work for you and follow their instructions for generating the symlinks or creating them manually.

On RPM-based distributions (like Fedora and CentOS), you use `chkconfig`:

```
chkconfig --add mysql
chkconfig --level 345 mysql on
```

On Debian-based distributions you use `update-rc.d`:

```
update-rc.d mysql defaults
```

On FreeBSD, the location for startup scripts is `/usr/local/etc/rc.d/` and when you copy the `mysql.server` script there you should rename it so that it matches the `*.sh` pattern, like so:

```
cd /path/to/your/mariadb/support-files/
cp mysql.server /usr/local/etc/rc.d/mysql.server.sh
```

As stated above, consult your distribution's documentation for more information on starting services like MariaDB at system startup.

See mariadbd startup options for information on configuration options for `mariadbd`.

This page is licensed: GPLv2

Running MariaDB From the Build Directory

You can run mariadbd directly from the build directory (without doing `make install`).

Starting mariadbd After Build on Windows

On Windows, the data directory is produced during the build.

The simplest way to start database from the command line is:

1. Go to the directory where mariadbd.exe is located (subdirectory `sql\Debug` or `sql\Relwithdebinfo` of the build directory)
2. From here, execute:

```
mariadbd.exe --console
```

Pass other server parameters on the command line, or store them in a `my.ini` configuration file and pass `--defaults-file=path\to\my.ini`.

The default search path on Windows for the `my.ini` file is:

- `GetSystemWindowsDirectory()`
- `GetWindowsDirectory()`
- `C:\`
- Directory where the executable is located

Starting mariadbd After Build on Unix

Copy the following to your '`~/.my.cnf`' file.

There are two lines you have to edit: '`datadir=`' and '`language=`'. Be sure to change them to match your environment.

```
# Example MariadB config file.
# You can copy this to one of:
# /etc/my.cnf to set global options,
# /mysql-data-dir/my.cnf to get server specific options or
# ~/my.cnf for user specific options.
#
# One can use all long options that the program supports.
# Run the program with --help to get a list of available options

# This will be passed to all MariaDB clients
[client]
#password=my_password
#port=3306
#socket=/tmp/mysql.sock

# Here is entries for some specific programs
# The following values assume you have at least 32M ram

# The mariadb server  (both [mysqld] and [mariadb] works here)
[mariadb]
#port=3306
#socket=/tmp/mysql.sock

# The following three entries caused mysqld 10.0.1-MariaDB (and possibly other versions) to abort...
# skip-locking
# set-variable  = key_buffer=16M

loose-innodb_data_file_path = ibdata1:1000M
loose-mutex-deadlock-detector
gdb

######### Fix the two following paths

# Where you want to have your database
datadir=/path/to/data/dir

# Where you have your mysql/MariaDB source + sql/share/english
language=/path/to/src/dir/sql/share/english

########## One can also have a different path for different versions, to simplify development.

[mariadb-10.1]
lc-messages-dir=/my/maria-10.1/sql/share

[mariadb-10.2]
lc-messages-dir=/my/maria-10.2/sql/share

[mysqldump]
quick
set-variable = max_allowed_packet=16M

[mysql]
no-auto-rehash

[myisamchk]
set-variable= key_buffer=128M
```

With the above file in place, go to your MariaDB source directory and execute:

```
./scripts/mariadb-install-db --srcdir=$PWD --datadir=/path/to/data/dir
```

- `$PWD` is the environment variable that points to your current directory. If you added `datadir` to your `my.cnf`, you don't have to specify this option.

Now you can start `mariadbd` in the debugger:

```
cd sql
ddd ./mariadbd &
```

Or start `mariadbd` on its own:

```
cd sql
./mariadbd &
```

After starting up `mariadbd` using one of the above methods (with the debugger or without), launch the client (as root if you don't have any users setup yet).

```
../client/mariadb
```

Using a Storage Engine Plugin

The simplest case is to compile the storage engine into MariaDB:

```
cmake -DWITH_PLUGIN_<plugin_name>=1` .
```

Another option is to point `mariadbd` to the storage engine directory:

```
./mariadbd --plugin-dir={build-dir-path}/storage/connect/.libs
```

This page is licensed: CC BY-SA / Gnu FDL

Running Multiple MariaDB Server Processes

It is possible to run multiple MariaDB Server processes on the same server, but there are certain things that need to be kept in mind. This page will go over some of those things.

Configuring Multiple MariaDB Server Processes

If multiple MariaDB Server process are running on the same server, then at minimum, you will need to ensure that the different instances do not use the same datadir, port, and socket. The following example shows these options set in an option file:

```
[client]
# TCP port to use to connect to mariadbd server
port=3306
# Socket to use to connect to mariadbd server
socket=/tmp/mysql.sock
[mariadb]
# TCP port to make available for clients
port=3306
#  Socket to make available for clients
socket=/tmp/mysql.sock
# Where MariaDB should store all its data
datadir=/usr/local/mysql/data
```

The above values are the defaults. If you would like to run multiple MariaDB Server instances on the same server, then you will need to set unique values for each instance.

There may be additional options that also need to be changed for each instance. Take a look at the full list of options for mariadbd.

To see the current values set for an instance, see Checking Program Options for how to do so.

To list the default values, check the end of the output of this command:

```
mariadbd --help --verbose
```

Starting Multiple MariaDB Server Processes

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually. See Starting and Stopping MariaDB for more information.

If you want to run different MariaDB versions on the same machine, using binary tarballs, Docker or using Virtual Machines (VMs) are the recommended ways. A binary tarball uses least resources, Docker a bit more and a VM uses most resources.

Service Managers

sysVinit and systemd are the most common Linux service managers. launchd is used in MacOS X. Upstart is a less common service manager.

Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use systemd by default.

For information on how to start and stop multiple MariaDB Server processes on the same server with this service manager, see systemd: Interacting with Multiple MariaDB Server Processes.

Starting the Server Process Manually

mariadbd

mariadbd is the actual MariaDB Server binary. It can be started manually on its own.

If you want to force each instance to read only a single option file, then you can use the –defaults-file option:

```
mariadbd --defaults-file=/etc/my_instance1.cnf
```

mariadbd-safe

mariadbd-safe is a wrapper that can be used to start the mariadbd server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See mariadbd-safe for more information.

If you want to force each instance to read only a single option file, then you can use the –defaults-file option:

```
mariadbd-safe --defaults-file=/etc/my_instance1.cnf
```

mariadbd-multi

mariadbd-multi is a wrapper that can be used to start the mariadbd server process if you plan to run multiple server processes on the same host. See mariadbd-multi for more information.

Other Options

In some cases, there may be easier ways to run multiple MariaDB Server instances on the same server, such as:

- Starting multiple Docker containers.
- Using dbdeployer (no longer maintained).

This page is licensed: CC BY-SA / Gnu FDL

Specifying Permissions for Schema (Data) Directories and Tables

Default File Permissions

By default MariaDB uses the following permissions for files and directories:

Object Type	Default Mode	Default Permissions
Files	0660	-rw-rw—-
Directories	0700	drwx——

Configuring File Permissions with Environment Variables

You can configure MariaDB to use different permissions for files and directories by setting the following environment variables before you start the server:

Object Type	Environment Variable
Files	UMASK
Directories	UMASK_DIR

In other words, if you would run the following in a shell:

```
export UMASK=0640
export UMASK_DIR=0750
```

These environment variables do not set the umask. They set the default file system permissions. See MDEV-23058 for more information.

Configuring File Permissions With systemd

If your server is started by systemd, then there is a specific way to configure the umask. See Systemd: Configuring the umask for more information.

This page is licensed: CC BY-SA / Gnu FDL

Switching Between Different Installed MariaDB Versions

This article is about managing many different installed MariaDB versions and running them one at a time. This is useful when doing benchmarking, testing, or for when developing different MariaDB versions.

This is most easily done using the tar files from mariadb.org/download/.

Stopping a Preinstalled MySQL/MariaDB From Interfering With Your Tests

If MySQL/MariaDB is already installed and running, you have two options:

1. Use test MariaDB servers with a different port & socket.

- In this case you are probably best off creating a specific section for MariaDB in your `~/.my.cnf` file.

2. Stop mysqld with `/etc/rc.d/mysql stop` or `mariadb-admin shutdown`.

Note that you don't have to uninstall or otherwise remove MySQL!

How to Create a Binary Distribution (tar File)

Here is a short description of how to generate a tar file from a source distribution. If you have downloaded a binary tar file, you can skip this section.

The steps to create a binary tar file are:

- Decide where to put the source. A good place is under `/usr/local/src/mariadb-5.#`.
- Get the source
- Compile the source
- Create the binary tar ball.

You will then be left with a tar file named something like: `mariadb-11.0.1-MariaDB-linux-x86_64.tar.gz`

Creating a Directory Structure for the Different Installations

Install the binary tar files under `/usr/local/` with the following directory names (one for each MariaDB version you want to use), for example:

- `mariadb-10.5`
- `mariadb-10.6`
- `mariadb-10.11`
- `mariadb-11.0`
- `mariadb-11.1`

The above assumes you are just testing major versions of MariaDB. If you are testing specific versions, use directory names like `mariadb-11.0.1`

With the directories in place, create a symlink named `mariadb` which points at the `mariadb-XXX` directory you are currently testing. When you want to switch to testing a different version, just update the symlink.

Example:

```
cd /usr/local
tar xfz /tmp/mariadb-11.0.1-linux-systemd-x86_64.tar.gz
mv -vi mariadb-11.0.1-MariaDB-systemd-linux-x86_64 mariadb-11.0
ln -vs mariadb-11.0 mariadb
```

Setting Up the Data Directory

When setting up the data directory, you have the option of either using a shared database directory or creating a unique database directory for each server version. For testing, a common directory is probably easiest. Note that you can only have one `mysqld` server running against one data directory.

Setting Up a Common Data Directory

The steps are:

1. Create the `mysql` system user if you don't have it already!
   (On Linux you do it with the `useradd` command).
2. Create the directory (we call it `mariadb-data` in the example below) or add a symlink to a directory which is in some other place.
3. Create the `mysql` permission tables with mariadb-install-db.

```
cd /usr/local/
mkdir mariadb-data
cd mariadb
./bin/mariadb-install-db --no-defaults --datadir=/usr/local/mariadb-data
chown -R mysql mariadb-data mariadb-data/*
```

The reason to use `--no-defaults` is to ensure that we don't inherit incorrect options from some old `my.cnf`.

Setting Up Different Data Directories

To create a different `data` directories for each installation:

```
cd mariadb
./scripts/mariadb-install-db --no-defaults
chown -R mysql mariadb-data mariadb-data/*
```

This will create a directory `data` inside the current directory.

If you want to use another disk, you should run this command:

```
cd mariadb
ln -s path-to-empty-directory-for-data data
./scripts/mariadb-install-db --no-defaults --datadir=./data
chown -R mysql mariadb-data mariadb-data/*
```

Running a MariaDB Server

The normal steps are:

```
rm mariadb
ln -s mariadb-# mariadb
cd mariadb
./bin/mysqld_safe --no-defaults --datadir=/usr/local/mariadb-data &
```

Setting Up a .my.cnf file for Running Multiple MariaDB Versions

If you are going to start/stop MariaDB a lot of times, you should create a `~/.my.cnf` file for the common options you are using.

The following example shows how to use a non-standard TCP-port and socket (to not interfere with a main MySQL/MariaDB server) and how to setup different options for each main server:

```
[client-server]
socket=/tmp/mysql.sock
port=3306
[mysqld]
datadir=/usr/local/mariadb-data

[mariadb-11.0]
# Options for MariaDB 11.0
[mariadb-11.1]
# Options for MariaDB 11.1
```

If you create an `~/.my.cnf` file, you should start `mysqld` with `--defaults-file=~/.my.cnf` instead of `--no-defaults` in the examples above.

This page is licensed: CC BY-SA / Gnu FDL

What to Do if MariaDB Doesn't Start

This page helps troubleshoot some of the more common reasons for MariaDB not starting, and provide solutions.

If you have tried everything here and still need help, you can ask for help on IRC or on the forums - see Where to find other MariaDB users and developers - or ask a question at the Starting and Stopping MariaDB page.

The Error Log and the Data Directory

The reason for the failure will almost certainly be written in the error log and, if you are starting MariaDB manually, to the console. By default, the error log is named *host-name*.err and is written to the data directory.

Common Locations:

- `/var/log/`
- `/var/log/mysql`
- `C:\Program Files\MariaDB x.y\data` (x.y refers to the version number)
- `C:\Program Files (x86)\MariaDB x.y\data` (32bit version on 64bit Windows)

It's also possible that the error log has been explicitly written to another location. This is often done by changing the datadir or log_error system variables in an option file. See the Option Files below for more information about that.

A quick way to get the values of these system variables is to execute the following commands:

```
mariadbd --help --verbose | grep 'log-error' | tail -1
mariadbd --help --verbose | grep 'datadir' | tail -1
```

Option Files

Another kind of file to consider when troubleshooting is option files. The default option file is called `my.cnf`. Option files contain configuration options, such as the location of the data directory mentioned above. If you're unsure where the option file is located, see Configuring MariaDB with Option Files: Default Option File Locations for information on the default locations.

You can check which configuration options MariaDB server will use from its option files by executing the following command:

```
mariadbd --print-defaults
```

You can also check by executing the following command:

```
my_print_defaults --mysqld
```

See Configuring MariaDB with Option Files: Checking Program Options for more information on checking configuration options.

Invalid Option or Option Value

Another potential reason for a startup failure is that an option file contains an invalid option or an invalid option value. In those cases, the error log should contain an error similar to this:

```
140514 12:19:37 [ERROR] /usr/local/mysql/bin/mariadbd: unknown variable 'option=value'
```

This is more likely to happen when you upgrade to a new version of MariaDB. In most cases, the option file from the old version of MariaDB will work just fine with the new version. However, occasionally, options are removed in new versions of MariaDB, or the valid values for options are changed in new versions of MariaDB. Therefore, it's possible for an option file to stop working after an upgrade.

Also, remember that option names are case sensitive.

Examine the specifics of the error. Possible fixes are usually one of the following:

- If the option is completely invalid, then remove it from the option file.
- If the option's name has changed, then fix the name.
- If the option's valid values have changed, then change the option's value to a valid one.
- If the problem is caused by a simple typo, then fix the typo.

Can't Open Privilege Tables

It is possible to see errors similar to the following:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

If errors like this occur, then critical system tables are either missing or are in the wrong location. The above error is quite common after an upgrade if the option files set the basedir or datadir to a non-standard location, but the new server is using the default location. Therefore, make sure that the basedir and datadir variables are correctly set.

If you're unsure where the option file is located, see Configuring MariaDB with Option Files: Default Option File Locations for information on the default locations.

If the system tables really do not exist, then you may need to create them with mariadb-install-db. See Installing System Tables (mariadb-install-db) for more information.

Can't Create Test File

One of the first tests on startup is to check whether MariaDB can write to the data directory. When this fails, it will log an error like this:

```
May 13 10:24:28 mariadb3 mariadbd[19221]: 2019-05-13 10:24:28 0 [Warning] Can't create test file
/usr/local/data/mariadb/mariadb3.lower-test
May 13 10:24:28 mariadb3 maridbd[19221]: 2019-05-13 10:24:28 0 [ERROR] Aborting
```

This is usually a permission error on the directory in which this file is being written. Ensure that the entire datadir is owned by the user running `mariadbd`, usually `mysql`. Ensure that directories have the "x" (execute) directory permissions for the owner. Ensure that all the parent directories of the datadir upwards have "x" (execute) permissions for all (`user`, `group`, and `other`).

Once this is checked, look at the systemd and SELinux documentation below, or AppArmor.

Can't Lock Aria Control File

On starting MariaDB, the `aria_log_control` file is locked. If a lock cannot be obtained, it will log an error like this:

```
2023-05-01 16:27:03 0 [ERROR] mariadbd: Can't lock aria control file '/var/lib/mysql/aria_log_control'
for exclusive use, error: 11. Will retry for 30 seconds
```

This almost always happens because there is already an existing MariaDB service running on this data directory. Recommend aborting this startup and looking closely for the other MariaDB instance.

A less likely case is that file locking is not available, which might occur on an NFS-mounted data directory without proper locking support.

Unable to Lock ./ibdata1 Error 11

Like the above for the Aria Control File, this is attempting to exclusively lock the `ibdata1` InnoDB system tablespace. Error 11 corresponds to the system error "OS error code 11: Resource temporarily unavailable," meaning the lock cannot be created.

```
2023-05-01 16:27:34 0 [ERROR] InnoDB: Unable to lock ./ibdata1 error: 11
2023-05-01 16:27:34 0 [Note] InnoDB: Check that you do not already have another mariadbd process using
the same InnoDB data or log files.
2023-05-01 16:27:34 0 [ERROR] InnoDB: Plugin initialization aborted with error Generic error
2023-05-01 16:27:35 0 [Note] InnoDB: Starting shutdown...
```

Like the above, this is an indication that a second MariaDB instance is already running on the data directory.

InnoDB

InnoDB is probably the MariaDB component that most frequently causes a crash. In the error log, lines containing InnoDB messages generally start with “InnoDB:”.

Cannot Allocate Memory for the InnoDB Buffer Pool

In a typical installation on a dedicated server, at least 70% of your memory should be assigned to the InnoDB buffer pool; sometimes it can even reach 85%. But be very careful: don’t assign to the buffer pool more memory than it can allocate. If it cannot allocate memory, InnoDB will use the disk’s swap area, which is very bad for performance. If swapping is disabled or the swap area is not big enough, InnoDB will crash. In this case, MariaDB will probably try to restart several times, and each time it will log a message like this:

```
140124 17:29:01 InnoDB: Fatal error: cannot allocate memory for the buffer pool
```

In that case, you will need to add more memory to your server/VM or decrease the value of the innodb_buffer_pool_size variable.

Remember that the buffer pool will slightly exceed that limit. Also, remember that MariaDB also needs to allocate memory for other storage engines and several per-connection buffers. The operating system also needs memory.

InnoDB Table Corruption

By default, InnoDB deliberately crashes the server when it detects table corruption. The reason for this behavior is preventing corruption propagation. However, in some situations, server availability is more important than data integrity. For this reason, we can avoid these crashes by changing the value of innodb_corrupt_table_action to ‘warn’.

If InnoDB crashes the server after detecting data corruption, it writes a detailed message in the error log. The first lines are similar to the following:

```
InnoDB: Database page corruption on disk or a failed
InnoDB: file read of page 7.
InnoDB: You may have to recover from a backup.
```

Generally, it is still possible to recover most of the corrupted data. To do so, restart the server in InnoDB recovery mode and try to extract the data that you want to backup. You can save them in a CSV file or in a non-InnoDB table. Then, restart the server in normal mode and restore the data.

MyISAM

Most tables in the mysql database are MyISAM tables. These tables are necessary for MariaDB to properly work or even start.

A MariaDB crash could cause system table corruption. With the default settings, MariaDB will simply not start if the system tables are corrupted. With myisam_recover_options, we can force MyISAM to repair damaged tables.

systemd

If you are using systemd, then there are a few relevant notes about startup failures:

- If MariaDB is configured to access files under `/home`, `/root`, or `/run/user`, then the default systemd unit file will prevent access to these directories with a `Permission Denied` error. This happens because the unit file sets ProtectHome=true. See Systemd: Configuring Access to Home Directories for information on how to work around this.
- The default systemd unit file also sets ProtectSystem=full, which places restrictions on writing to a few other directories. Overwriting this with `ProtectSystem=off` in the same way as above will restore access to these

directories.

- If MariaDB takes longer than 90 seconds to start, then the default systemd unit file will cause it to fail with an error. This happens because the default value for the TimeoutStartSec option is 90 seconds. See Systemd: Configuring the Systemd Service Timeout for information on how to work around this.
- The systemd journal may also contain useful information about startup failures. See Systemd: Systemd Journal for more information.

See systemd documentation for further information on systemd configuration.

SELinux

Security-Enhanced Linux (SELinux) is a Linux kernel module that provides a framework for configuring a mandatory access control (MAC) system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distributions. SELinux prevents programs from accessing files, directories, or ports unless it is configured to access those resources.

You might need to troubleshoot SELinux-related issues in cases such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

Setting SELinux state to `permissive` is a common way to investigate what is going wrong while allowing MariaDB to function normally. `permissive` is supposed to produce a log entry every time it should block a resource access, without actually blocking it. However, there are situations when SELinux blocks resource accesses even in `permissive` mode.

See SELinux for more information.

AppArmor

Add the following to `/etc/apparmor.d/tunables/alias` if you have moved the datadir:

```
alias /var/lib/mysql/ -> /data/mariadb/,
```

The restart AppArmor:

```
sudo systemctl restart apparmor
```

AppArmor on newer Ubuntu and Debian releases

In Ubuntu 26.04 “Resolute Raccoon”, Debian 14 “Forky”, and newer releases of these distributions, the MariaDB packages ship with a **custom AppArmor profile** which is enabled by default.

In the event of unexplained errors at startup or runtime, check for potential AppArmor denials with `aa-status | grep mariadb` or `sudo dmesg | grep -i apparmor`.

To disable enforcement, run `aa-complain /etc/apparmor.d/mariadbd`.

To add local overrides, put them in `/etc/apparmor.d/local/mariadbd`. For more information, see /usr/share/doc/mariadb-server/NEWS.Debian.gz.

Why to Automate MariaDB Deployments and Management

MariaDB includes a powerful configuration system. This is enough when we need to deploy a single MariaDB instance, or a small number of instances. But many modern organisations have many database servers. Deploying

and upgrading them manually could require too much time, and would be error-prone.

Infrastructure as Code

Several tools exist to deploy and manage several servers automatically. These tools operate at a higher level, and execute tasks like installing MariaDB, running queries, or generating new configuration files based on a template. Instead of upgrading servers manually, users can launch a command to upgrade a group of servers, and the automation software will run the necessary tasks.

Servers can be described in a code repository. This description can include MariaDB version, its configuration, users, backup jobs, and so on. This code is human-readable, and can serve as a documentation of which servers exist and how they are configured. The code is typically versioned in a repository, to allow collaborative development and track the changes that occurred over time. This is a paradigm called **Infrastructure as Code**.

Automation code is high-level and one usually doesn't care how operations are implemented. Their implementation is delegated to modules that handle specific components of the infrastructure. For example a module could equally work with apt and yum package managers. Other modules can implement operations for a specific cloud vendor, so we declare we want a snapshot to be done, but we don't need to write the commands to make it happen. For special cases, it is of course possible to write Bash commands, or scripts in every language, and declare that they must be run.

Manual interventions on the servers will still be possible. This is useful, for example, to investigate performance problems. But it is important to leave the servers in the state that is described by the code.

This code is not something you write once and never touch again. It is periodically necessary to modify infrastructures to update some software, add new replicas, and so on. Once the base code is in place, making such changes is often trivial and potentially it can be done in minutes.

Automated Failover

Once replication is in place, two important aspects to automate are load balancing and failover.

Proxies can implement load balancing, redirecting the queries they receive to different server, trying to distribute the load equally. They can also monitor that MariaDB servers are running and in good health, thus avoiding sending queries to a server that is down or struggling.

However, this does not solve the problem with replication: if a primary server crashes, its replicas should point to another server. Usually this means that an existing replica is promoted to a master. This kind of changes are possible thanks to MariaDB GTID.

One can promote a replica to a primary by making change to existing automation code. This is typically simple and relatively quick to do for a human operator. But this operation takes time, and in the meanwhile the service could be down.

Automating failover will minimise the time to recover. A way to do it is to use Orchestrator, a tool that can automatically promote a replica to a primary. The choice of the replica to promote is done in a smart way, keeping into account things like the servers versions and the binary log format.

Comparison Between Automation Systems

This page compares the automation systems that are covered by this section of the MariaDB documentation. More information about these systems are presented in the relevant pages, and more systems may be added in the future.

Code Structure Differences

Different automation systems provide different ways to describe our infrastructure. Understanding how they work is the first step to evaluate them and choose one for our organization.

ANSIBLE

Ansible code consists of the following components:

- An inventory determines which hosts Ansible should be able to deploy. Each host may belong to one or more groups. Groups may have children, forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A role describes the state that a host, or group of hosts, should reach after a deploy.
- A play associates hosts or groups to their roles. Each role/group can have more than one role.
- A role consists of a list of tasks. Despite its name a task is not necessarily something to do, but something that must exist in a certain state.
- Tasks can use variables. They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- Playbooks are the code that is used to define tasks and variables.
- Facts are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- Modules implement actions that tasks can use. Action examples are file (to declare that files and directories must exist) or mysql_variables (to declare MySQL/MariaDB variables that need to be set).

See Ansible Overview - concepts for more details and an example.

PUPPET

Puppet code consists of the following components:

- An inventory file defines a set of groups and their targets (the members of a group). plugins can be used to retrieve groups and target dynamically, so they are equivalent to Ansible dynamic inventories.
- A manifest is a file that describes a configuration.
- A resource is a component that should run on a server. For example, “file” and “service” are existing support types.
- An attribute relates to a resource and affects the way it is applied. For example, a resource of type “file” can have attributes like “owner” and “mode”.
- A class groups resources and variables, describing a logical part of server configuration. A class can be associated to several servers. A class is part of a manifest.
- A module is a set of manifests and describes an infrastructure or a part of it.
- Classes can have typed parameters that affect how they are applied.
- Properties are variables that are read from the remote server, and cannot be arbitrarily assigned.
- Facts are pre-set variables collected by Puppet before applying or compiling a manifest.

Architectural Differences

The architecture of the various systems is different. Their architectures determine how a deploy physically works, and what is needed to be able to deploy.

ANSIBLE

Ansible architecture is simple. Ansible can run from any host, and can apply its playbooks on remote hosts. To do this, it runs commands via SSH. In practice, in most cases the commands will be run as superuser via `sudo`, though this is not always necessary.

Inventories can be dynamic. In this case, when we apply a playbook Ansible connects to remote services to discover hosts.

Ansible playbooks are applied via the `ansible-playbook` binary. Changes to playbooks are only applied when we perform this operation.

To recap, Ansible does not need to be installed on the server is administers. It needs an SSH access, and normally its user needs to be able to run `sudo`. It is also possible to configure a dynamic inventory, and a remote service to be used for this purpose.

PUPPET

Puppet Architecture

Puppet supports two types of architecture: agent-master or standalone. The agent-master architecture is recommended by Puppet Labs, and it is the most popular among Puppet users. For this reason, those who prefer a standalone architecture tend to prefer Ansible.

Agent-Master Architecture

When this architecture is chosen, manifests are sent to the **Puppet master**. There can be more than one master, for high availability reasons. All target hosts run a **Puppet agent**. Normally this is a service that automatically starts at system boot. The agent contacts a master at a given interval. It sends facts, and uses them to compile a **catalog** from the manifests. A catalog is a description of what exactly an individual server should run. The agent receives the catalog and checks if there are differences between its current configuration and the catalog. If differences are found, the agent applies the relevant parts of the catalog.

An optional component is **PuppetDB**. This is a central place where some data are stored, including manifests, retrieved facts and logs. PuppetDB is based on PostgreSQL and there are no plans to support MariaDB or other DBMSs.

If a manual change is made to a remove server, it will likely be overwritten the next time Puppet agent runs. To avoid this, the Puppet agent service can be stopped.

Standalone Architecture

As mentioned, this architecture is not recommended by Puppet Labs nor popular amongst Puppet users. It is similar to Ansible architecture.

Users can apply manifests from any host with Puppet installed. This could be their laptop but, in order to emulate the behavior of an agent-master architecture, normally Puppet runs on a dedicated node as a cronjob. The **Puppet apply** application will require facts from remote hosts, it will compile a catalog for each host, will check which parts of it need to be applied, and will apply them remotely.

If a manual change is made to a remove server, it will be overwritten the next time Puppet apply runs. To avoid this, comment out any cron job running Puppet apply, or comment out the target server in the inventory.

Inventory

> As mentioned, Puppet supports plugins to retrieve the inventory dynamically from remote services. In an agent-master architecture, one has to make sure that each target host has access to these services. In a standalone architecture, one has to make sure that the hosts running Puppet apply have access to these services.

Storing Secrets

Often our automation repositories need to contain secrets, like MariaDB user passwords or private keys for SSH authentication.

Both Ansible and Puppet support integration with secret stores, like Hashicorp Vault.

> **ANSIBLE**
>
> Ansible allows encrypting secrets in playbooks and decrypting them during execution using ansible-vault. This implies a minimal effort to handle secrets. However, it is not the most secure way to store secrets. The passwords to disclose certain secrets need to be shared with the users who have the right to use them. Also, brute force attacks are possible.
>
> **PUPPET**
>
> For Puppet integration, see Integrations with secret stores.

Ecosystems and Communities

Automation software communities are very important, because they make available a wide variety of modules to handle specific software.

> **ANSIBLE**
>
> Ansible is open source, released under the terms of the GNU GPL. It is produced by RedHat. RedHat has a page about Red Hat Ansible Automation Platform Partners, who can provide support and consulting.
>
> Ansible Galaxy is a big repository of Ansible roles produced by both the vendor and the community. Ansible comes with `ansible-galaxy`, a tool that can be used to create roles and upload them to Ansible Galaxy.
>
> At the time of this writing, Ansible does not have specific MariaDB official modules. MySQL official modules can be used. However, be careful not try to use features that only apply to MySQL. There are several community-maintained MariaDB roles.
>
> **PUPPET**
>
> Puppet is open source, released under the GNU GPL. It is produced by a homonym company. The page Puppet Partners lists partners that can provide support and consulting about Puppet.
>
> Puppet Forge is a big repository of modules produced by the vendor and by the community, as well as how-to guides.
>
> Currently Puppet has many MariaDB modules.

Automating MariaDB Tasks with Events

MariaDB has an event scheduler that can be used to automate tasks, making them run at regular intervals of time. This page is about using events for automation. For more information about events themselves, and how to work with them, see event scheduler.

Pros and Cons of Using Events for Automation

Events can be compared to Unix cron jobs or Windows scheduled tasks. MariaDB events have at least the following benefits compared to those tools:

- Events are system-independent. The same code can run on any system.
- Events are written in procedural SQL. There is no need to install other languages or libraries.
- If you use user-defined functions, you can still take advantage of them in your events.
- Events run in MariaDB. An implication, for example, is that the results of queries remain in MariaDB itself and are not sent to a client. This means that network glitches don't affect events, there is no overhead due to data roundtrip, and therefore locks are held for a shorter time.

Some drawbacks of using events are the following:

- Events can only perform tasks that can be developed in SQL. So, for example, it is not possible to send alerts. Access to files or remote databases is limited.
- The event scheduler runs as a single thread. This means that events that are scheduled to run while another event is running will wait until the other event has stopped. This means that there is no guarantee that an event will run on exactly it's scheduled time. This should not be a problem as long as one ensures that events are short lived.
- For more events limitations, see Event Limitations.

In many cases you may prefer to develop scripts in an external programming language. However, you should know that simple tasks consisting of a few queries can easily be implemented as events.

Good Practices

When using events to automate tasks, there are good practices one may want to follow.

Move your SQL code in a stored procedure. All the event will do is to call a stored procedures. Several events may call the same stored procedure, maybe with different parameters. The procedure may also be called manually, if necessary. This will avoid code duplication. This will separate the logic from the schedule, making it possible to change an event without a risk of making changes to the logic, and the other way around.

Just like cron jobs, events should log whether if they succeed or not. Logging debug messages may also be useful for non-trivial events. This information can be logged into a dedicated table. The contents of the table can be monitored by a monitoring tool like Grafana. This allows to visualize in a dashboard the status of events, and send alerts in case of a failure.

Examples

Some examples of tasks that could easily be automated with events:

- Copying data from a remote table to a local table by night, using the CONNECT storage engine. This can be a good idea if many rows need be copied, because data won't be sent to an external client.
- Periodically delete historical data. For example, rows that are older than 5 years. Nothing prevents us from doing this with an external script, but probably this wouldn't add any value.

- Periodically delete invalid rows. In an e-commerce, they could be abandoned carts. In a messaging system, they could be messages to users that don't exist anymore.
- Add a new partition to a table and drop the oldest one (partition rotation).

Automating Upgrades with MariaDB.Org Downloads REST API

The MariaDB Foundation maintains a Downloads REST API. See the Downloads API documentation to find out all the tasks that you can accomplish with this API. Generally speaking, we can say that it provides information about MariaDB products and available versions. This allows to easily automate upgrades for MariaDB and related products.

The Downloads API exposes HTTPS endpoints that return information in JSON format. HTTP and JSON are extremely common standards that can be easily used with any programming language. All the information provided by the API is public, so no authentication is required.

How to Use the API with a Unix Shell

Linux shells are great for writing simple scripts. They are compatible to each other to some extent, so simple scripts can be run on almost any Unix/Linux system. In the following examples we'll use Bash.

On Linux, some programs you'll generally need to work with any REST API are:

- curl, to call HTTP URLs and get their output.
- js, to extract or transform information from a JSON document.

Example: Check When a New Version Becomes GA

A trivial use case is to write a script that checks the list of MariaDB GA major versions and, when something changes, send us an email. So we can test the newest GA version and eventually install it.

The script in this example will be extremely simple. We'll do it this way:

- Retrieve the JSON object describing all MariaDB versions.
- For each element of the array, only show the `release_id` and `release_status` properties, and concatenate them.
- Apply a filter, so we only select the rows containing 'stable' but not 'old' (so we exclude 'Old Stable').
- From the remaining rows, only show the first column (the version number).
- If the results we obtained are different from the previously written file (see last point) send an email.
- Save the results into a file.

This is something that we can easily do with a Unix shell:

```
#!/bin/bash

current_ga_versions=$(
    curl https://downloads.mariadb.org/rest-api/mariadb/ | \
    jq -r '.major_releases[] | .release_id + " " + .release_status' | \
    grep -i 'stable' | grep -vi 'old' | \
    cut -d ' ' -f 1
)

# create file if it doesn't exist, then compare version lists
touch ga_versions
previous_ga_versions=$( cat ga_versions )

echo "$current_ga_versions" > ga_versions

if [ "$current_ga_versions" != "$previous_ga_versions" ];
then
    mail -s 'NOTE: New MariaDB GA Versions' devops@example.com <<< 'There seems to be a new MariaDB GA
version! Yay!'
fi
```

The only non-standard command here is jq. It is a great way to manipulate JSON documents, so if you don't know it you may want to take a look at jq documentation.

How to Use the API with a Python Script

To use the API with Python, we need a module that is able to send HTTP requests and parse a JSON output. The `requests` module has both these features. It can be installed as follows:

```
pip install requests
```

The following script prints stable versions to the standard output:

```
#!/usr/bin/env python

import requests

response = requests.get('https://downloads.mariadb.org/rest-api/mariadb/').json()

for x in response['major_releases']:
    if x['release_status'] == 'Stable':
        print(x['release_id'])
```

`requests.get()` makes an HTTP call of type GET, and `requests.json()` returns a dictionary representing the previously obtained JSON document.

HashiCorp Vault and MariaDB

Vault is open source software for secret management provided by HashiCorp. It is designed to avoid sharing secrets of various types, like passwords and private keys. When building automation, Vault is a good solution to avoid storing secrets in plain text in a repository.

Important:

Unsafe Operations
It is unsafe to execute `vault secrets disable` or `vault token revoke` while MariaDB is running. Abruptly removing access to the Vault could prevent InnoDB from encrypting data pages during background flushes or log writes, which can lead to a server crash.

Tip:

Always ensure the MariaDB server has completed a clean shutdown before disabling Vault secrets or revoking access tokens.

MariaDB and Vault may relate to each other in several ways:

- MariaDB has a Hashicorp Key Management plugin, to manage and rotate SSH keys.
- Users passwords can be stored in Vault.
- MariaDB (and MySQL) can be used as a secret engine, a component which stores, generates, or encrypts data.
- MariaDB (and MySQL) can be used as a backend storage, providing durability for Vault data.

For information about how to install Vault, see Install Vault, as well as MySQL/MariaDB Database Secrets Engine.

Note:

Namespace support is available as of MariaDB Enterprise Server 11.8.

See the Hashicorp namespaces documentation for details.

Vault Features

Vault is used via an HTTP/HTTPS API.

Vault is identity-based. Users login and Vault sends them a token that is valid for a certain amount of time, or until certain conditions occur. Users with a valid token may request to obtain secrets for which they have proper permissions.

Vault encrypts the secrets it stores.

Vault can optionally audit changes to secrets and secrets requests by the users.

Vault Architecture

Vault is a server. This allows decoupling the secrets management logic from the clients, which only need to login and keep a token until it expires.

The sever can actually be a cluster of servers, to implement high availability.

The main Vault components are:

- Storage Backed: This is where the secrets are stored. Vault only send encrypted data to the backend storage.
- HTTP API: This API is used by the clients, and provides an access to Vault server.
- Barrier: Similarly to an actual barrier, it protects all inner Vault components. The HTTP API and the storage backend are outside of the barrier and could be accessed by anyone. All communications from and to these components have to pass through the barrier. The barrier verifies data and encrypts it. The barrier can have two states: sealed or unsealed. Data can only pass through when the barrier is unsealed. All the following components are located inside the barrier.
- Auth Method: Handles login attempts from clients. When a login succeeds, the auth method returns a list of security policies to Vault core.
- Token Store: Here the tokens generated as a result of a succeeded login are stored.

- Secrets Engines: These components manage secrets. They can have different levels of complexity. Some of them simply expect to receive a key, and return the corresponding secret. Others may generate secrets, including one-time-passwords.
- Audit Devices: These components log the requests received by Vault and the responses sent back to the clients.There may be multiple devices, in which case an Audit Broker sends the request or response to the proper device.

Dev Mode

It is possible to start Vault in dev mode:

```
vault server -dev
```

Dev mode is useful for learning Vault, or running experiments on some particular features. It is extremely insecure, because dev mode is equivalent to starting Vault with several insecure options. This means that Vault should never run in production in dev mode. However, this also means that all the regular Vault features are available in dev mode.

Dev mode simplifies all operations. Actually, no configuration is necessary to get Vault up and running in dev mode. It makes it possible to communicate with the Vault API from the shell without any authentication. Data is stored in memory by default. Vault is unsealed by default, and if explicitly sealed, it can be unsealed using only one key.

For more details, see “Dev” Server Mode in Vault documentation.

Orchestrator Overview

Orchestrator is no longer actively maintained.

Orchestrator is a MySQL and MariaDB high availability and replication management tool. It is released by Shlomi Noach under the terms of the Apache License, version 2.0.

Orchestrator provides automation for MariaDB replication in the following ways:

- It can be used to perform certain operations, like repairing broken replication or moving a replica from one master to another. These operations can be requested using CLI commands, or via the GUI provided with Orchestrator. The actual commands sent to MariaDB are automated by Orchestrator, and the user doesn’t have to worry about the details.
- Orchestrator can also automatically perform a failover in case a master crashes or is unreachable by its replicas. If that is the case, Orchestrator will promote one of the replicas to a master. The replica to promote is chosen based on several criteria, like the server versions, the binary log formats in use and the datacenters locations.

Note that, if we don’t want to use Orchestrator to automate operations, we can still use it as a dynamic inventory. Other tools can use it to obtain a list of existing MariaDB servers via its REST API or CLI commands.

Orchestrator has several big users, listed in the documentation Users page. It is also included in the PMM monitoring solution.

To install Orchestrator, see:

- The install.md for a manual installation;
- The links in README.md, to install Orchestrator using automation tools.

Supported Topologies

Currently, Orchestrator fully supports MariaDB GTID, replication, and semi-synchronous replication. While Orchestrator does not support Galera specific logic, it works with Galera clusters. For details, see Supported Topologies and Versions in Orchestrator documentation.

Architecture

Orchestrator consists of a single executable called `orchestrator`. This is a process that periodically connects to the target servers. It will run SQL queries against target servers, so it needs a user with proper permissions. When the process is running, a GUI is available via a web browser, at the URL 'localhost:3000'. It also exposes a REST API (see Using the web API in the Orchestrator documentation).

Orchestrator expects to find a JSON configuration file called `orchestrator.conf.json`, in `/etc`.

A database is used to store the configuration and the state of the target servers. By default, this is done using built-in SQLite. However, it is possible to use an external MariaDB or MySQL server instance.

If a cluster of Orchestrator instances is running, only one central database is used. One Orchestrator node is active, while the others are passive and are only used for failover. If the active node crashes or becomes unreachable, one of the other nodes becomes the active instance. The `active_node` table shows which node is active. Nodes communicate between them using the Raft protocol.

CLI Examples

As mentioned, Orchestrator can be used from the command-line. Here you can find some examples.

List clusters:

```
orchestrator -c clusters
```

Discover a specified instance and add it to the known topology:

```
orchestrator -c discover -i <host>:<port>
```

Forget about an instance:

```
orchestrator -c topology -i <host>:<port>
```

Move a replica to a different master:

```
orchestrator -c move-up -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Move a replica up, so that it becomes a "sibling" of its master:

```
orchestrator -c move-up -i <replica-host>:<replica-port>
```

Move a replica down, so that it becomes a replica of its"sibling":

```
orchestrator -c move-below -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Make a node read-only:

```
orchestrator -c set-read-only -i <host>:<port>
```

Make a node writeable:

```
orchestrator -c set-writeable -i <host>:<port>
```

The `--debug` and `--stack` options can be added to the above commands to make them more verbose.

Orchestrator Resources and References

- Orchestrator on GitHub.
- Documentation.
- Raft consensus protocol website.

The README.md file lists some related community projects, including modules to automate Orchestrator with Puppet and other technologies.

On GitHub you can also find links to projects that allow the use of automation software to deploy and manage Orchestrator.

Ansible Overview for MariaDB Users

Ansible is a tool to automate servers configuration management. It is produced by Red Hat and it is open source software released under the terms of the GNU GPL.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Ansible.

For information about how to install Ansible, see Installing Ansible in Ansible documentation.

Automation Hubs

Normally, Ansible can run from any computer that has access to the target hosts to be automated. It is not uncommon that all members of a team has Ansible installed on their own laptop, and use it to deploy.

Red Hat offers a commercial version of Ansible called Ansible Tower. It consists of a REST API and a web-based interface that work as a hub that handles all normal Ansible operations.

An alternative is AWX. AWX is the open source upstream project from which many Ansible Tower features are originally developed. AWX is released under the terms of the Apache License 2.0. However, Red Hat does not recommend to run AWX in production.

AWX development is fast. It has several features that may or may not end up in Ansible Tower. Ansible Tower is more focused on making AWS features more robust, providing a stable tool to automate production environments.

Design Principles

Ansible allows us to write **playbooks** that describe how our servers should be configured. Playbooks are lists of **tasks**.

Tasks are usually **declarative**. You don't explain *how* to do something, you declare *what* should be done.

Playbooks are **idempotent**. When you apply a playbook, tasks are only run if necessary.

Here is a task example:

```
- name: Install Perl
  package:
    name: perl
    state: present
```

"Install Perl" is just a description that will appear on screen when the task is applied. Then we use the `package` module to declare that a package called "perl" should be installed. When we apply the playbook, if Perl is already installed nothing happens. Otherwise, Ansible installs it.

When we apply a playbook, the last information that appears on the screen is a recap like the following:

```
PLAY RECAP
*********************************************************************************************
mariadb-01        : ok=6    changed=2    unreachable=0    failed=0    skipped=0    rescued=0    ignored=0
```

This means that six tasks were already applied (so no action was taken), and two tasks were applied.

As the above example shows, Ansible playbooks are written in YAML.

Modules (like `package`) can be written in any language, as long as they are able to process a JSON input and produce a JSON output. However the Ansible community prefers to write them in Python, which is the language Ansible is written in.

Concepts

A piece of Ansible code that can be applied to a server is called a **playbook**.

A **task** is the smallest brick of code in a playbook. The name is a bit misleading, though, because an Ansible task should not be seen as “something to do”. Instead, it is a minimal description of a component of a server. In the example above, we can see a task.

A task uses a single **module**, which is an interface that Ansible uses to interact with a specific system component. In the example, the module is “package”.

A task also has attributes, that describe what should be done with that module, and how. In the example above, “name” and “state” are both attributes. The `state` attribute exists for every module, by convention (though there may be exceptions). Typically, it has at least the “present” and “absent” state, to indicate if an object should exist or not.

Other important code concepts are:

- An inventory determines which hosts Ansible should be able to deploy. Each host may belong to one or more groups. Groups may have children, forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A role describes the state that a host, or group of hosts, should reach after a deploy.
- A play associates hosts or groups to their roles. Each role/group can have more than one role.
- A role is a playbook that describes how certain servers should be configured, based on the logical role they have in the infrastructure. Servers can have multiple roles, for example the same server could have both the “mariadb” and the “mydumper” role, meaning that they run MariaDB and they have mydumper installed (as shown later).
- Tasks can use variables. They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- Facts are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- Modules implement actions that tasks can use. Action examples are file (to declare that files and directories must exist) or mysql_variables (to declare MySQL/MariaDB variables that need to be set).

Example

Let’s describe a hypothetical infrastructure to find out how these concepts can apply to MariaDB.

The **inventory** could define the following groups:

- “db-main” for the cluster used by our website. All nodes belong to this group.
- “db-analytics” for our replicas used by data analysts.
- “dump” for one or more servers that take dumps from the replicas.
- “proxysql” for one or more hosts that run ProxySQL.

Then we’ll need the following nodes:

- `mariadb-node` for the nodes in `db-main`. This role describes how to setup nodes of a cluster using Galera.
- `mariadb-replica` for the members of `db-analytics`. It describes a running replica, and it includes the tasks that are necessary to provision the node if the data directory is empty when the playbook is applied. The hostname of the primary server is defined in a variable.
- `mariadb`. The aforementioned `mariadb-node` and `mariadb-replica` can be children of this group. They have many things in common (filesystem for the data directory, some basic MariaDB configuration, some installed tools…), so it could make sense to avoid duplication and describe the common traits in a super-role.
- A `mariadb-backup` role to take backups with mariadb-backup, running jobs during the night. We can associate this role to the “ `db-main` ” group, or we could create a child group for servers that will take the backups.

- `mariadb-dump` for the server that takes dumps with mariadb-dump. Note that we may decide to take dumps on a replica, so the same host may belong to `db-analytics` and `mariadb-dump`.
- `proxysql` for the namesake group.

Architecture

Ansible architecture is extremely simple. Ansible can run on any host. To apply playbooks, it connects to the target hosts and runs system commands. By default the connection happens via ssh, though it is possible to develop connection plugins to use different methods. Applying playbooks locally without establishing a connection is also possible.

Modules can be written in any language, though Python is the most common choice in the Ansible community. Modules receive JSON "requests" and facts from Ansible core, they are supposed to run useful commands on a target host, and then they should return information in JSON. Their output informs Ansible whether something has changed on the remote server and if the operations succeeded.

Ansible is not centralized. It can run on any host, and it is common for a team to run it from several laptops. However, to simplify things and improve security, it may be desirable to run it from a dedicated host. Users will connect to that host, and apply Ansible playbooks.

Deploying Docker Containers with Ansible

Ansible can be used to manage Docker container upgrades and configuration changes. Docker has native ways to do this, namely Dockerfiles and Docker Compose. But sometimes there are reasons to start basic containers from an image and then manage configuration with Ansible or similar software. See Benefits of Managing Docker Containers with Automation Software.

In this page we'll discuss how to use Ansible to manage Docker containers.

How to Deploy a Container with Ansible

Ansible has modules to manage the Docker server, Docker containers, and Docker Compose. These modules are maintained by the community.

A dynamic inventory plugin for Docker exists. It retrieves the list of existing containers from Docker.

Docker modules and the Docker inventory plugin communicate with Docker using its API. The connection to the API can use a TSL connection and supports key authenticity verification.

To communicate with Docker API, Ansible needs a proper Python module installed on the Ansible node (`docker` or `docker-py`).

Several roles exist to deploy Docker and configure it. They can be found in Ansible Galaxy.

Deploying to Remote Servers with Ansible

If we manage several remote servers, running commands on them manually can be frustrating and time consuming. Ansible allows one to run commands on a whole group of servers.

This page shows some examples of ansible-playbook invocations. We'll see how to deploy roles or parts of them to remote servers. Then we'll see how to run commands on remote hosts, and possibly to get information from them. Make sure to read Ansible Overview first, to understand Ansible general concepts.

Pinging Remote Servers

Let's start with the simplest example: we just want our local Ansible to ping remote servers to see if they are reachable. Here's how to do it:

```
ansible -i production-mariadb all -m ping
```

Before proceeding with more useful examples, let's discuss this syntax.

- ansible is the executable we can call to run a command from remote servers.
- -i production-mariadb means that the servers must be read from an inventory called production-mariadb.
- all means that the command must be executed against all servers from the above inventory.
- -m ping specifies that we want to run the ping module. This is not the ping Linux command. It tells us if Ansible is able to connect a remote server and run a simple commands on them.

To run ping on a specific group or host, we can just replace "all" with a group name or host name from the inventory:

```
ansible -i production-mariadb main_cluster -m ping
```

Running Commands on Remote Servers

The previous examples show how to run an Ansible module on remote servers. But it's also possible to run custom commands over SSH. Here's how:

```
ansible -i production-mariadb all -a 'echo $PATH'
```

This command shows the value of `$PATH` on all servers in the inventory "production-mariadb".

We can also run commands as root by adding the `-b` (or `--become`) option:

```
# print a MariaDB variable
ansible -i production-mariadb all -b -a 'mysql -e "SHOW GLOBAL VARIABLES LIKE
\'innodb_buffer_pool_size\';"'

# reboot servers
ansible -i production-mariadb all -b -a 'reboot'
```

Applying Roles to Remote Servers

We saw how to run commands on remote hosts. Applying roles to remote hosts is not much harder, we just need to add some information. An example:

```
ansible-playbook -i production-mariadb production-mariadb.yml
```

Let's see what changed:

- ansible-playbook is the executable file that we need to call to apply playbooks and roles.
- production-mariadb.yml is the play that associates the servers listed in the inventory to their roles.

If we call ansible-playbook with no additional arguments, we will apply all applicable roles to all the servers mentioned in the play.

To only apply roles to certain servers, we can use the `-l` parameter to specify a group, an individual host, or a pattern:

```
# Apply to the mariadb-main role role
ansible-playbook -i production-mariadb -l mariadb-main production-mariadb.yml

# Apply to the mariadb-main-01 host
ansible-playbook -i production-mariadb -l mariadb-main-01 production-mariadb.yml

# Apply to multiple hosts whose name starts with "mariadb-main-"
ansible-playbook -i production-mariadb -l mariadb-main-* production-mariadb.yml
```

We can also apply tasks from roles selectively. Tasks may optionally have tags, and each tag corresponds to an operation that we may want to run on our remote hosts. For example, a "mariadb" role could have the "timezone-update" tag, to update the contents of the timezone tables. To only apply the tasks with the "timezone-update" tag, we can use this command:

```
ansible-playbook -i production-mariadb --tag timezone-update production-mariadb.yml
```

Using tags is especially useful for database servers. While most of the technologies typically managed by Ansible are stateless (web servers, load balancers, etc.) database servers are not. We must pay special attention not to run tasks that could cause a database server outage, for example destroying its data directory or restarting the service when it is not necessary.

Check mode

We should always test our playbooks and roles on test servers before applying them to production. However, if test servers and production servers are not exactly in the same state (which means, some facts may differ) it is still possible that applying roles will fail. If it fails in the initial stage, Ansible will not touch the remote hosts at all. But there are cases where Ansible could successfully apply some tasks, and fail to apply another task. After the first failure, ansible-playbook will show errors and exit. But this could leave a host in an inconsistent state.

Ansible has a *check mode* that is meant to greatly reduce the chances of a failure. When run in check mode, ansible-playbook will read the inventory, the play and roles; it will figure out which tasks need to be applied; then it will connect to target hosts, read facts, and value all the relevant variables. If all these steps succeed, it is unlikely that running ansible-playbook without check mode will fail.

To run ansible-playbook in check mode, just add the `--check` (or `-C`) parameter.

Existing Ansible Modules and Roles for MariaDB

This page contains links to Ansible modules and roles that can be used to automate MariaDB deployment and configuration. The list is not meant to be exhaustive. Use it as a starting point, but then please do your own research.

Modules

At the time of writing, there are no MariaDB-specific modules in Ansible Galaxy. MySQL modules can be used. Trying to use MySQL-specific features may result in errors or unexpected behavior. However, the same applies when trying to use a feature not supported by the MySQL version in use.

Currently, the MySQL collection in Ansible Galaxy contains at least the following modules:

- mysql_db: manages MySQL databases.
- mysql_info: gathers information about a MySQL server.
- mysql_query: runs SQL queries against MySQL.
- mysql_replication: configures and operates asynchronous replication.
- mysql_user: creates, modifies and deletes MySQL users.
- mysql_variables: manages MySQL configuration.

Note that some modules only exist as shortcuts, and it is possible to use mysql_query instead. However, it is important to notice that mysql_query is not idempotent. Ansible does not understand MySQL queries, therefore it cannot check whether a query needs to be run or not.

To install this collection locally:

```
ansible-galaxy collection install community.mysql
```

MariaDB Corporation maintains a ColumnStore playbook on GitHub.

Other Useful Modules

Let's see some other modules that are useful to manage MariaDB servers.

shell and command

Modules like shell and command allow one to run system commands.

To deploy on Windows, win_shell and win_command can be used.

Among other things, it is possible to use one of these modules to run MariaDB queries:

```
- name: Make the server read-only
  # become root to log into MariaDB with UNIX_SOCKET plugin
  become: yes
  shell: $( which mysql ) -e "SET GLOBAL read_only = 1;"
```

The main disadvantage with these modules is that they are not idempotent, because they're meant to run arbitrary system commands that Ansible can't understand. They are still useful in a variety of cases:

- To run queries, because mysql_query is also not idempotent.
- In cases when other modules do not allow us to use the exact arguments we need to use, we can achieve our goals by writing shell commands ourselves.
- To run custom scripts that implement non-trivial logic. Implementing complex logic in Ansible tasks is possible, but it can be tricky and inefficient.
- To call command-line tools. There may be specific roles for some of the most common tools, but most of the times using them is an unnecessary complication.

copy and template

An important part of configuration management is copying configuration files to remote servers.

The copy module allows us to copy files to target hosts. This is convenient for static files that we want to copy exactly as they are. An example task:

```
- name: Copy my.cnf
  copy:
    src: ./files/my.cnf.1
    dest: /etc/mysql/my.cnf
```

As you can see, the local name and the name on remote host don't need to match. This is convenient, because it makes it easy to use different configuration files with different servers. By default, files to copy are located in a `files` subdirectory in the role.

However, typically the content of a configuration file should vary based on the target host, the group and various variables. To do this, we can use the template module, which compiles and copies templates written in Jinja.

A simple template task:

```
- name: Compile and copy my.cnf
  copy:
    src: ./templates/my.cnf.j2
    dest: /etc/mysql/my.cnf
```

Again, the local and the remote names don't have to match. By default, Jinja templates are located in a `templates` subdirectory in the role, and by convention they have the `.j2` extension. This is because Ansible uses Jinja version 2 for templating, at the time writing.

A simple template example:

```
## WARNING: DO NOT EDIT THIS FILE MANUALLY !!
## IF YOU DO, THIS FILE WILL BE OVERWRITTEN BY ANSIBLE

[mysqld]
innodb_buffer_pool_size = {{ innodb_buffer_pool_size }}

<div data-gb-custom-block data-tag="if" data-0='true' data-1='true' data-2='true' data-3='true'>

connect_work_size = {{ connect_work_size }}

</div>
```

Other Common Modules

The following modules are also often used for database servers:

- package, apt or yum. Package is package manager-agnostic. Use them to install, uninstall and upgrade packages.
- user, useful to create the system user and group that run MariaDB binary.
- file can be used to make sure that MariaDB directories (like the data directory) exist and have proper permissions. It can also be used to upload static files.
- template allows to create configuration files (like `my.cnf`) more dynamically, using the Jinja template language.
- service is useful after installing MariaDB as a service, to start it, restart it or stop it.

Roles

Specific roles exist for MariaDB in Ansible Galaxy. Using them for MariaDB is generally preferable, to be sure to avoid incompatibilities and to probably be able to use some MariaDB specific features. However, using MySQL or Percona Server roles is also possible. This probably makes sense for users who also administer MySQL and Percona Server instances.

To find roles that suits you, check Ansible Galaxy search page. Most roles are also available on GitHub.

You can also search roles using the ansible-galaxy tool:

```
ansible-galaxy search mariadb
```

Content initially contributed by Vettabase Ltd.

This page is licensed: CC BY-SA / Gnu FDL

Installing MariaDB .deb Files with Ansible

This page refers to the operations described in Installing MariaDB .deb Files. Refer to that page for a complete list and explanation of the tasks that should be performed.

Here we discuss how to automate such tasks using Ansible. For example, here we show how to install a package or how to import a GPG key; but for an updated list of the necessary packages and for the keyserver to use, you should refer to Installing MariaDB .deb Files.

Adding apt Repositories

To add a repository:

```
- name: Add specified repository into sources list
  ansible.builtin.apt_repository:
    repo: deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu
bionic main
    state: present
```

If you prefer to keep the repository information in a source list file in the Ansible repository, you can upload that file to the target hosts in this way:

```
- name: Create a symbolic link
  ansible.builtin.file:
    src: ./file/mariadb.list
    dest: /etc/apt/sources.list.d/
    owner: root
    group: root
    mod: 644
    state: file
```

Updating the Repository Cache

Both the Ansible modules ansible.builtin.apt and ansible.builtin.apt_repository have an `update_cache` attribute. In ansible.builtin.apt it is set to “no” by default. Whenever a task sets it to ‘yes’, `apt-get update` is run on the target system. You have three ways to make sure that repositories are updated.

The first is to use ansible.builtin.apt_repository to add the desired repository, as shown above. So you only need to worry about updating repositories if you use the file method.

The second is to make sure that `update_cache` is set to ‘yes’ when you install a repository:

```
- name: Install foo
  apt:
    name: foo
    update_cache: yes
```

But if you run certain tasks conditionally, this option may not be very convenient. So the third option is to update the repository cache explicitly as a separate task:

```
- name: Update repositories
  apt:
    - update_cache: yes
```

Importing MariaDB GPG Key

To import the GPG key for MariaDB we can use the ansible.builtin.apt_key Ansible module. For example:

```
- name: Add an apt key by id from a keyserver
  ansible.builtin.apt_key:
    keyserver: hkp://keyserver.ubuntu.com:80
    id: 0xF1656F24C74CD1D8
```

Installing Packages

To install Deb packages into a system:

```
- name: Install software-properties-common
  apt:
    name: software-properties-common
    state: present
```

To make sure that a specific version is installed, performing an upgrade or a downgrade if necessary:

```
- name: Install foo 1.0
  apt:
    name: foo=1.0
```

To install a package or upgrade it to the latest version, use: `state: latest`.

To install multiple packages at once:

```
- name: Install the necessary packages
  apt:
    pkg:
    - pkg1
    - pkg2=1.0
```

If all your servers run on the same system, you will always use ansible.builtin.apt and the names and versions of the packages will be the same for all servers. But suppose you have some servers running systems from the Debian family, and others running systems from the Red Hat family. In this case, you may find convenient to use two different task files for two different types of systems. To include the proper file for the target host's system:

```
- include: mariadb-debian.yml
  when: "{{ ansible_facts['os_family'] }} == 'Debian'
```

The variables you can use to run the tasks related to the proper system are:

- ansible_fact ['distribution']
- ansible_fact ['distribution_major_version']
- ansible_fact ['os_family']

There is also a system-independent package module, but if the package names depend on the target system using it may be of very little benefit.

Managing Secrets in Ansible

An Ansible role often runs commands that require certain privileges, so it must perform some forms of login, using passwords or key pairs. In the context of database automation, we normally talk about: SSH access, sudo access, and access to MariaDB. If we write these secrets (passwords or private keys) in clear text in an Ansible repository, anyone who has access to the repository can access them, and this is not what we want.

Let's see how we can manage secrets.

The SSH Password or Keys

Most of the times, Ansible connects to the target hosts via SSH. It is common to use the system username and the SSH keys installed in `/.ssh`, which is the SSH clients default. In this case, nothing has to be done on the clients to be able to allow Ansible to use SSH, as long as they are already able to connect to the target hosts.

It is also possible to specify a different username as ANSIBLE_REMOTE_USER and an SSH configuration file as ANSIBLE_NETCONF_SSH_CONFIG. These settings can be specified in Ansible configuration file or as environment variables.

ANSIBLE_ASK_PASS can be specified. If this is the case, Ansible will prompt the user asking to type an SSH password.

Avoiding Sharing Secrets

As a general rule, any configuration that implies communicating sensible information to the persons who will connects to a system implies some degree of risk. Therefore, the most common choice is to allow users to login into remote systems with their local usernames, using SSH keys.

Once Ansible is able to connect remote hosts, it can also be used to install the public keys of some users to grant them access. Sharing these keys implies no risk. Sharing private keys is never necessary, and must be avoided.

MariaDB has a UNIX_SOCKET plugin that can be used to let some users avoid entering a password, as far as they're logged in the operating system. This authentication method is used by default for the root user. This is a good way to avoid having one more password and possibly writing to a `.my.cnf` file so that the user doesn't have to type it.

Even for users who connect remotely, it is normally not necessary to insert passwords in an Ansible file. When we create a user with a password, a hash of the original password is stored in MariaDB. That hash can be found in the mysql.user table. To know the hash of a password without even creating a user, we can use the PASSWORD() function:

```
SELECT PASSWORD('my_password12') AS hash;
```

When we create a user, we can actually specify a hash instead of the password the user will have to type:

```
CREATE USER user@host IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

ansible-vault

Even if you try to avoid sharing secrets, it's likely you'll have to keep some in Ansible. For example, MariaDB users that connect remotely have passwords, and if we want Ansible to create and manage those users, the hashes must be placed somewhere in our Ansible repository. While a hash cannot be converted back to a password, treating hashes as secrets is usually a good idea. Ansible provides a native way to handle secrets: ansible-vault.

In the simplest case, we can manage all our passwords with a single ansible-vault password. When we add or change a new password in some file (typically a file in `host_vars` or `group_vars`) we'll use ansible-vault to crypt this password. While doing so, we'll be asked to insert our ansible-vault password. When we apply a role and Ansible needs to decrypt this password, it will ask us to enter again our ansible-vault password.

ansible-vault can use more than one password. Each password can manage a different set of secrets. So, for example, some users may have the password to manage regular MariaDB users passwords, and only one may have the password that is needed to manage the root user.

Running mariadb-tzinfo-to-sql with Ansible

For documentation about the `mariadb-tzinfo-to-sql` utility, see mysql_tzinfo_to_sql. This page is about running it using Ansible.

Installing or Upgrading the Package

First, we should install `mariadb-tzinfo-to-sql` if it is available on our system. For example, to install it on Ubuntu, we can use this task. For other systems, use the proper module and package name.

```
- name: Update timezone info
  tags: [ timezone-update ]
  apt:
    name: tzdata
    state: latest
    install_recommends: no
  register: timezone_info
```

This task installs the latest version of the `tzdata`, unless it is already installed and up to date. We register the `timezone_info` variables, so we can only run the next task if the package was installed or updated.

We also specify a `timezone-update` tag, so we can apply the role to only update the timezone tables.

Running the Script

The next task runs `mariadb-tzinfo-to-sql`.

```
- name: Move system timezone info into MariaDB
  tags: [ timezone-update ]
  shell: >
    mysql_tzinfo_to_sql /usr/share/zoneinfo \
      | grep -v "^Warning" \
      | mysql --database=mysql
  when: timezone_info.changed
```

We use the `shell` module to run the command. Running a command in this way is not idempotent, so we specify `when: timezone_info.changed` to only run it when necessary. Some warnings may be generated, so we pipe the output of `mysql_tzinfo_to_sql` to `grep` to filter warnings out.

Using Galera

If we're using MariaDB Galera Cluster we'll want to only update the timezone tables in one node, because the other nodes will replicate the changes. For our convenience, we can run this operation on the first node. If the nodes hostnames are defined in a list called `cluster_hosts`, we can check if the current node is the first in this way:

```
when: timezone_info.changed and inventory_hostname == cluster_hosts[0].hostname
```

Puppet and MariaDB

See Puppet Overview.

Introduction to Puppet's architecture (agent-master vs. standalone), concepts like manifests and catalogs, and how it can be used for configuration management of MariaDB servers.

See Deploying Docker Containers with Puppet.

A guide to managing Docker container lifecycles using Puppet's `docker` resource type, covering image pulling, container execution, and upgrades for MariaDB.

See Existing Puppet Modules for MariaDB.

Lists available Puppet modules for MariaDB from the Puppet Forge and GitHub, noting that while no official module exists, community and generic MySQL modules are often used.

See Puppet hiera Configuration System.

Explains how to use Hiera, Puppet's hierarchical key/value lookup tool, to separate MariaDB configuration data from code and manage environment-specific settings.

See Bolt Examples.

Demonstrates how to use Bolt, an orchestration tool in the Puppet ecosystem, to run ad-hoc commands, scripts, and tasks on remote MariaDB servers without a permanent agent.

This page is licensed: CC BY-SA / Gnu FDL

Puppet Overview

Puppet is a tool to automate servers configuration management. It is produced by Puppet Inc, and released under the terms of the Apache License, version 2.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Puppet.

Puppet modules can be searched using Puppet Forge. Most of them are also published on GitHub with open source licenses. Puppet Forge allows filtering modules to only view the most reliable: supported by Puppet, supported by a Puppet partner, or approved.

For information about installing Puppet, see Installing and upgrading in Puppet documentation.

Design Principles

With Puppet, you write **manifests** that describe the resources you need to run on certain servers and their **attributes**.

Therefore manifests are **declarative**. You don't write the steps to achieve the desired result. Instead, you describe the desired result. When Puppet detects differences between your description and the current state of a server, it decides what to do to fix those differences.

Manifests are also **idempotent**. You don't need to worry about the effects of applying a manifest twice. This may happen (see Architecture below) but it won't have any side effects.

Defining Resources

Here's an example of how to describe a resource in a manifest:

```
file { '/etc/motd':
  content => '',
  ensure => present,
}
```

This block describes a resource. The resource type is `file`, while the resource itself is `/etc/motd`. The description consists of a set of attributes. The most important is `ensure`, which in this case states that the file must exist. It is also common to use this resource to indicate that a file (probably created by a previous version of the manifest) doesn't exist.

These classes of resource types exist:

- Built-in resources, or Puppet core resources: Resources that are part of Puppet, maintained by the Puppet team.
- Defined resources: Resources that are defined as a combination of other resources. They are written in the Puppet domain-specific language.
- Custom resources: Resources that are written by users, in the Ruby language.

To obtain information about resources:

```
# list existing resource types
puppet resource --typesupp
# print information about the file resource type
puppet describe file
```

To group several resources in a reusable class:

```
class ssh_server {
  file { '/etc/motd':
    content => '',
    ensure => present,
  }
  file { '/etc/issue.net':
    content => '',
    ensure => present,
  }
}
```

There are several ways to include a class. For example:

```
include Class['ssh_server']
```

Defining Nodes

Puppet has a **main manifest** that could be a `site.pp` file or a directory containing `.pp` files. For simple infrastructures, we can define the nodes here. For more complex infrastructures, we may prefer to import other files that define the nodes.

Nodes are defined in this way:

```
node 'maria-1.example.com' {
  include common
  include mariadb
}
```

The resource type is `node`. Then we specify a hostname that is used to match this node to an existing host. This can also be a list of hostnames, a regular expression that matches multiple nodes, or the `default` keyword that matches all hosts. To use a regular expression:

```
node /^(maria|mysql)-[1-3]\.example\.com$/ {
  include common
}
```

Concepts

The most important Puppet concepts are the following:

Concepts	Definition
Target	A host whose configuration is managed via Puppet.
Group	A logical group of targets. Example: `mariadb` group.
Facts	Information collected from targets (e.g., system name/version) using Facter. Can be core or custom facts.
Manifest	A description that can be applied to a target.
Catalog	A compiled manifest.
Apply	Modifying a target's state to reflect its manifest description.
Module	A set of manifests.
Resource	A minimal piece of description in a manifest describing system components like files or services.
Resource Type	Determines the class of a resource, e.g., `file` resource type with multiple resources describing different files.
Attribute	Characteristic of a resource, like file owner or mode.
Class	A group of resources reusable across several manifests.

Architecture

Depending on how the user decides to deploy changes, Puppet can use two different architectures:

- An Agent-master architecture. This is the preferred way to use Puppet.
- A standalone architecture, that is similar to Ansible architecture.

Agent-master Architecture

A **Puppet master** stores a catalog for each target. There may be more than one Puppet master, for redundancy.

Each target runs a **Puppet agent** in background. Each Puppet agent periodically connects to the Puppet master, sending its facts. The Puppet master compiles the relevant manifest using the facts it receives, and send back a catalog. Note that it is also possible to store the catalogs in PuppetDB instead.

Once the Puppet agent receives the up-to-date catalog, it checks all resources and compares them with its current state. It applies the necessary changes to make sure that its state reflects the resources present in the catalog.

Standalone Architecture

With this architecture, the targets run **Puppet apply**. This application usually runs as a Linux cron job or a Windows scheduled task, but it can also be manually invoked by the user.

When Puppet apply runs, it compiles the latest versions of manifests using the local facts. Then it checks every resource from the resulting catalogs and compares it to the state of the local system, applying changes where needed.

Newly created or modified manifests are normally deployed to the targets, so Puppet apply can read them from the local host. However it is possible to use PuppetDB instead.

PuppetDB

PuppetDB is a Puppet node that runs a PostgreSQL database to store information that can be used by other nodes. PuppetDB can be used with both the Agent-master and the standalone architectures, but it is always optional. However it is necessary to use some advanced Puppet features.

PuppetDB stored the following information:

- The latest facts from each target.
- The latest catalogs, compiled by Puppet apply or a Puppet master.
- Optionally, the recent history of each node activities.

External Node Classifiers

With both architectures, it is possible to have a component called an External Node Classifier (ENC). This is a script or an executable written in any language that Puppet can call to determine the list of classes that should be applied to a certain target.

An ENC received a node name in input, and should return a list of classes, parameters, etc, as a YAML hash.

Bolt

Bolt can be used in both architectures to run operations against a target or a set of targets. These operations can be commands passed manually to Bolt, scripts, Puppet tasks or plans. Bolt directly connects to targets via ssh and runs system commands.

See Bolt Examples to get an idea of what you can do with Bolt.

hiera

hiera is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

See Puppet hiera Configuration System for more information.

Deploying Docker Containers with Puppet

Puppet can also be used to manage Docker container upgrades and configuration changes. Docker has more specific tools for this purpose, but sometimes there are reasons to choose alternatives. See Benefits of Managing Docker Containers with Automation Software.

In this page you will find out what managing Docker with Puppet looks like. All the snippets in this page use the `docker` resource type, supported by the Puppet company.

How to Install, Upgrade or Uninstall Docker with Puppet

Installing or upgrading Docker is simple:

```
class { 'docker':
  use_upstream_package_source => false,
  version => '17.09.0~ce-0~debian',
}
```

In this example we are using our system's repositories instead of Docker official repositories, and we are specifying the desired version. To upgrade Docker later, all we need to do is to modify the version number. While specifying a version is not mandatory, it is a good idea because it makes our manifest more reproducible.

To uninstall Docker:

```
class { 'docker':
  ensure => absent
}
```

Check the `docker` resource type documentation to find out how to use more features: for example you can use Docker Enterprise Edition, or bind the Docker daemon to a TCP port.

How to Build or Pull Docker Images with Puppet

To pull an image from Dockerhub:

```
docker::image { 'mariadb:10.0': }
```

We specified the `10.0` tag to get the desired MariaDB version. If we don't, the image with the `latest` tag will be used. Note that this is not desirable in production, because it can lead to unexpected upgrades.

You can also write a Dockerfile yourself, and then build it to create a Docker image. To do so, you need to instruct Puppet to copy the Dockerfile to the target and then build it::

```
file { '/path/to/remote/Dockerfile':
  ensure => file,
  source => 'puppet:///path/to/local/Dockerfile',
}

docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
}
```

It is also possible to subscribe to Dockerfile changes, and automatically rebuild the image whenever a new file is found:

```
docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
  subscribe => File['/path/to/remote/Dockerfile'],
}
```

To remove an image that was possibly built or pulled:

```
docker::image { 'mariadb':
  ensure => absent
}
```

How to Deploy Containers with Puppet

To run a container:

```
docker::run { 'mariadb-01':
    image   => 'mariadb:10.5',
    ports   => ['3306:6606']
}
```

`mariadb-01` is the contained name. We specified the optional `10.5` tag, and we mapped the guest port `3306` to the host port `6606`. In production, you normally don't map ports because you don't need to connect MariaDB clients from the host system to MariaDB servers in the containers. Third-party tools can be installed as separate containers.

Existing Puppet Modules for MariaDB

This page contains links to Puppet modules that can be used to automate MariaDB deployment and configuration. The list is not meant to be exhaustive. Use it as a starting point, but then please do your own research.

Puppet Forge

Puppet Forge is the website to search for Puppet modules, maintained by the Puppet company. Modules are searched by the technology that needs to be automated, and the target operating system.

Search criteria include whether the modules are supported by Puppet or its partners, and whether a module is approved by Puppet. Approved modules are certified by Puppet based on their quality and maintenance standards.

Acceptance Tests

Some modules that support the Puppet Development Kit allow some types of acceptance tests.

We can run a static analysis on a module's source code to find certain bad practices that are likely to be a source of bugs:

```
pdk validate
```

If a module's authors wrote unit tests, we can run them in this way:

```
pdk test unit
```

Supported Modules for MariaDB

At the time of writing, there are no supported or approved modules for MariaDB.

However there is a mysql module supported by Puppet, that supports the Puppet Development Kit. Though it doesn't support MariaDB-specific features, it works with MariaDB. Its documentation shows how to use the module to install MariaDB on certain operating systems.

Several unsupported and not approved modules exist for MariaDB and MaxScale.

Puppet hiera Configuration System

hiera is part of Puppet. It is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

hiera Configuration Files

Each hierarchy allows to one choose the proper configuration file for a resource, based on certain criteria. For example criteria may include node names, node groups, operating systems, or datacenters. Hierarchies are defined in a `hiera.yaml` file, which also defines a path for the files in each hierarchy.

Puppet facts are commonly used to select the proper files to use. For example, a path may be defined as `"os/%{facts.os.name}.yaml"`. In this case, each resource will use a file named after the operating system it uses, in the

os directory. You may need to use custom facts, for example to check which microservices will use a MariaDB server, or in which datacenter it runs.

We do not have to create a file for each possible value of a certain fact. We can define a default configuration file with settings that are reasonable for most resources. Other files, when included, will override some of the default settings.

A hiera configuration file will look like this:

```
version: 5
defaults:
  datadir: global
  data_hash: yaml_data

hierarchy:
  - name: "Node data"
    path: "nodes/%{trusted.certname}.yaml"

  - name: "OS data"
    path: "os/%{facts.os.family}.yaml"

  - name: "Per-datacenter business group data" # Uses custom facts.
    path: "location/%{facts.whereami}/%{facts.group}.yaml"
```

This file would include the global files, the OS-specific files and the node-specific files. Each hierarchy will override settings from previous hierarchies.

We can actually have several hiera configuration files. `hiera.yaml` is the global file. But we will typically have additional hiera configuration files for each environment. So we can include the configuration files that apply to production, staging, etc, plus global configuration files that should be included for every environment.

Importantly, we can also have hiera configuration files for each module. So, for example, a separate `mariadb/hiera.yaml` file may defined the hierarchies for MariaDB servers. This allow us to define, for example, different configuration files for MariaDB and for MaxScale, as most of the needed settings are typically different.

Configuration Files

You probably noticed that, in the previous example, we defined `data_hash: yaml_data`, which indicates that configuration files are written in YAML. Other allowed formats are JSON and HOCON. The `data_hash` setting is defined in `defaults`, but it can be overridden by hierarchies.

Bolt Examples

This page shows some examples of what we can do with Bolt to administer a set of MariaDB servers. Bolt is a tool that is part of the Puppet ecosystem.

For information about installing Bolt, see Installing Bolt in Bolt documentation.

Inventory Files

The simplest way to call Bolt and instruct it to do something on some remote targets is the following:

```
bolt ... --nodes 100.100.100.100,200.200.200.200,300,300,300,300
```

However, for non-trivial setups it is usually better to use an inventory file. An example:

```
targets:
  - uri: maria-1.example.com
    name: maria_1
    alias: mariadb_main
  ...
```

In this way, it will be possible to refer the target by name or alias.

We can also define groups, followed by the group members. For example:

```
groups:
  - name: mariadb-staging
    targets:
        - uri: maria-1.example.com
        name: maria_1
        - uri: maria-2.example.com
        name: maria_2
  - name: mariadb-production
    targets:
      ...
...
```

With an inventory of this type, it will be possible to run Bolt actions against all the targets that are members of a group:

```
bolt ... --nodes mariadb-staging
```

In the examples in the rest of the page, the `--targets` parameter will be indicated in this way, for simplicity: `--targets <targets>`.

Running Commands on Targets

The simplest way to run a command remotely is the following:

```
bolt command run 'mariadb-admin start-all-slaves' --targets <targets>
```

Copying Files

To copy a file or a whole directory to targets:

```
bolt file upload /path/to/source /path/to/destination --targets <targets>
```

To copy a file or a whole directory from the targets to the local host:

```
bolt file download /path/to/source /path/to/destination --targets <targets>
```

Running Scripts on Targets

We can use Bolt to run a local script on remote targets. Bolt will temporarily copy the script to the targets, run it, and delete it from the targets. This is convenient for scripts that are meant to only run once.

```
bolt script run rotate_logs.sh --targets <targets>
```

Running Tasks on Targets

Puppet tasks are not always as powerful as custom scripts, but they are simpler and many of them are idempotent. The following task stops MariaDB replication:

```
bolt task run mysql::sql --targets <targets> sql="STOP REPLICA"
```

Applying Puppet Code on Targets

It is also possible to apply whole manifests or portions of Puppet code (resources) on the targets.

To apply a manifest:

```
bolt apply manifests/server.pp  --targets <targets>
```

To apply a resource description:

```
bolt apply --execute "file { '/etc/mysql/my.cnf': ensure => present }" --targets <targets>
```

MariaDB Containers

Containers are an OCI standard format for software images and their specified time all bundled up into a single distributable time. They can be used for production, development or testing.

Docker Inc. run a Docker Official Images program to provide users with an essential base implementation of MariaDB in a container and to exemplify best practices of a container.

The containers are available on Docker Hub as **docker.io/library/mariadb** though many container runtime implementation will fill in the **docker.io/library** where the host/path isn't specified.

The containers are in a Open Container Initiative format that allows the containers to be interoperable with a number of container runtime implementations. Docker, or more fully Docker Engine, is just one of the many available runtimes.

Many people use MariaDB Docker Official Image containers in CI systems like GitHub Actions, though its possible to use these in production environments like kubernetes.

The MariaDB Server container images are available with a number of tags:

- A full version, like 10.11.5
- A major version like 10.11
- The most recent stable GA version - latest
- The most recent stable LTS version - lts

Versions that aren't stable will be suffixed with **-rc**, or **-alpha** to clearly show their release status, and enables Renovatebot and other that follow semantic versioning to follow updates.

For a consistent application between testing an production environment using the SHA hash of the image is recommended like **docker.io/library/mariadb@sha256:29fe5062baf36bae8ec68f21a3dce4f0372dadc185e687624f1252fc49d91c67**. There is a list of mapping and history of tags to SHA hash on the Docker Library repository.

Adding Plugins to the MariaDB Docker Official Image

MariaDB has many plugins. Most are not enabled by default, some are in the `mariadb` container, while others need to be installed from additional packages.

The following methods summarize Installing plugins in the MariaDB Docker Library Container (mariadb.org blog post) on this topic.

Which Plugins Does the Container Contain?

To see which plugins are available in the mariadb:

```
$ docker run --rm mariadb:latest ls -C /usr/lib/mysql/plugin
```

Enabling a Plugin Using Flags

Using the `--plugin-load-add` flag with the plugin name (can be repeated), the plugins will be loaded and ready when the container is started:

For example, to enable the `simple\_password\_check` plugin:

```
$ docker run --name some-%%REPO%% -e MARIADB_ROOT_PASSWORD=my-secret-pw --network=host -d mariadb:latest
--plugin-load-add=simple_password_check
```

Enabling a Plugin in the Configuration Files

plugin-load-add` can be used as a configuration option to load plugins. The example below loads the FederatedX Storage Engine.

```
$ printf "[mariadb]\nplugin-load-add=ha_federatedx\n" > /my/custom/federatedx.conf
$ docker run --name some-mariadb -v /my/custom:/etc/mysql/conf.d -e MARIADB_ROOT_PASSWORD=my-secret-pw -d
mariadb:latest
```

Install a Plugin Using SQL in /docker-entrypoint-initdb.d

INSTALL SONAME can be used to install a plugin as part of the database initialization.

Create the SQL file used in initialization:

```
$ echo 'INSTALL SONAME "disks";' > my_initdb/disks.sql
```

In this case, the `my\_initdb` is a `/docker-entrypoint-initdb.d` directory per “Initializing a fresh instance” section above.

Identifying Additional Plugins in Additional Packages

A number of plugins are in separate packages to reduce their installation size. The package names of MariaDB-created plugins can be determined using the following command:

```
$ docker run --rm mariadb:latest sh -c 'apt-get update -qq && apt-cache search mariadb-plugin'
```

Creating an Image With Plugins From Additional Packages

A new image needs to be created when using additional packages. The `mariadb` image can however be used as a base:

In the following, the CONNECT Storage Engine is installed:

```
FROM mariadb:latest
RUN apt-get update && \
    apt-get install mariadb-plugin-connect -y && \
    rm -rf /var/lib/apt/lists/*
```

Installing plugins from packages creates a configuration file in the directory `/etc/mysql/mariadb.conf.d/` that loads the plugin on startup.

This page is licensed: CC BY-SA / Gnu FDL

Benefits of Managing MariaDB Containers with Orchestration Software

In this page we'll discuss why automating containers with software like Ansible or Puppet may be desirable in some cases. To talk about this, we'll first need to discuss why containers are defined *ephemeral*, and how this applies to containerized database servers (particularly MariaDB).

During the discussion, we should keep in mind that Docker Engine, CRI-I, containerd, Mirantis Container Runtime, Podman and other OCI container runtimes can be used to setup production and/or development environments. These use cases are very different from a database perspective: a production database may be big, and typically contains data that we don't want to lose. Development environments usually contain small sample data that can be rebuilt relatively quickly. This page focuses on the latter case.

Container Ephemeral Nature

Images are an OCI specified format that can be compiled from Dockerfiles as one of the ways. Containers are the OCI runtime specified way of creating a runtime version of an images. Normally, a container is not modified from the moment it is created. In other words, containers are usually designed to be **ephemeral**, meaning that they can be destroyed and replaced with new containers at any time. Provided that there is proper redundancy (for example, there are several web servers running the same services) destroying one container and starting a new one of the same type won't cause any damage.

We will discuss a bit later how this applies to MariaDB, and more generally to database servers.

When something should change, for example some software version or configuration, normally Dockerfiles are updated and containers are recreated from the latest image versions. For this reason, containers shouldn't contain anything that shouldn't be lost, and recreating them should be an extremely cheap operation. **Docker Compose** or the **Swarm mode** are used to declare which containers form a certain environment, and how they communicate with each other.

On the contrary, Ansible and Puppet are mainly built to manage the configuration of existing servers. It doesn't recreate servers, it changes their configuration. So Docker and Ansible have very different approaches. For this reason, Ansible and Puppet are not frequently used to deploy containers to production. However, using them together can bring some benefits, especially for development environments.

More on this later in the page. First, we need to understand how these concepts apply to database servers.

Stateful Technologies

Using ephemeral containers works very well for *stateless* technologies, like web servers and proxies. These technologies virtually only need binaries, configuration and small amounts of data (web pages). If some data need to be restored after a container creation, it will be a fast operation.

In the case of a database, the problem is that data can be large and need to be written somewhere. We don't want all databases to disappear when we destroy a container. Even if we had an up-to-date backup, restoring it would take time.

However, OCI Containers has features called **volumes**. A volume is a directory in the host system mapped to a directory in one or more containers. Volumes are not destroyed when containers are destroyed. They can be used to share data between any number of containers and the host system. Therefore, they are also a good way to persist data.

Suppose a MariaDB container called `mariadb-main-01` uses a volume that is mapped to `/var/docker/volumes/mariadb-main`. At some point we want to use a more recent MariaDB version. As explained earlier, the container way to do this is to destroy the container and create a new one that uses a more recent version of the MariaDB image.

So, we will destroy `mariadb-main-01`. The volume is still there. Then we create a new container with the same name, but based on a newer image. We make sure to link the volume to the new container too, so it will be able to use `/var/docker/volumes/mariadb-main` again. At this point we may want to run mariadb-upgrade, but apart from that, everything should *just work*.

The container runtime implementations also provide the opportunity to create a volume with an explicit name and this is also persistent. The actual location on the filesystem is managed by the runtime.

The above described steps are simple, but running them manually is time consuming and error-prone. Automating them with some automation software like Ansible or Puppet is often desirable.

Ways to Deploy Containers

Containers can be deployed in the following ways:

- Manually. See Installing and Using MariaDB via Docker. This is not recommended for production, or for complex environments. However, it can easily be done for the simplest cases. If we want to make changes to our custom images, we'll need to modify the Dockerfiles, destroy the containers and recreate them.
- With Docker Compose. See Setting Up a LAMP Stack with Docker Compose for a simple example. When we modify a Dockerfile, we'll need to destroy the containers and recreate them, which is usually as simple as running `docker compose down` followed by `docker compose up`. After changing `docker-cmpose.yml` (maybe to add a container or a network) we'll simply need to run `docker compose up` again, because it is idempotent.
- Using Ansible, Puppet or other automation software, as mentioned before. We can use Ansible or Puppet to create the containers, and run them again every time we want to apply some change to the containers. This means that the containers are potentially created once and modified any number of times.

In all these cases, it is entirely possible to add Vagrant to the picture. Vagrant is a way to deploy or provision several hosts, including virtual machines (the most common case), and containers. It is agnostic in regarding the underlying technology, so it can deploy to a virtual machine, a container, or even a remote server in the same way. Containers can work with Vagrant in two ways:

- As a provisioner. In this case Vagrant will most commonly deploy a virtual machine, and will use Docker to setup the applications that need to run in it, as containers. This guarantees a higher level of isolation, compared to

running the containers in the local host. Especially if you have different environments to deploy locally, because you can have them on different virtual machines.

- As a provider. Vagrant will deploy one or more containers locally. Once each container is up, Vagrant can optionally use a provisioner on it, to make sure that the container runs the proper software with proper configuration. In this case, Ansible, Puppet or other automation software can be used as a provisioner. But again, this is optional: it is possible to make changes to the Dockerfiles and recreate the containers every time.

Benefits of Managing Containers with Automation Software

Containers can be entirely managed with Docker Compose or the Swarm mode. This is often a good idea.

However, choosing to use automation software like Ansible or Puppet has some benefits too. Benefits include:

- Containers allow working without modifying the host system, and their creation is very fast. Much faster than virtual machines. This makes containers desirable for development environments.
- As explained, making all containers ephemeral and using volumes to store important data is possible. But this means adding some complexity to adapt an ephemeral philosophy to technologies that are not ephemeral by nature (databases). Also, many database professionals don't like this approach. Using automation software allows easily triggering upgrades and configuration changes in the containers, treating them as non-ephemeral systems.
- Sometimes containers are only used in development environments. If production databases are managed via Ansible, Puppet, or other automation software, this could lead to some code duplication. Dealing with configuration changes using the same procedures will reduce the cost of maintenance.
- While recreating containers is fast, being able to apply small changes with Ansible or Puppet can be more convenient in some cases: particularly if we write files into the container itself, or if recreating a container bootstrap involves some lengthy procedure.
- Trying to do something non-standard with Dockerfiles can be tricky. For example, running two processes in a container is possible but can be problematic, as containers are designed to run single main process per container. However there are situations when this is desirable. For example PMM containers run several different processes. Launching additional processes with Ansible or Puppet may be easier than doing it with a Dockerfile.

With all this in mind, let's see some examples of cases when managing containers with Ansible, Puppet or other automation software is preferable, rather than destroying containers every time we want to make a change:

- We use Ansible or Puppet in production, and we try to keep development environments as similar as possible to production. By using Ansible/Puppet in development too, we can reuse part of the code.
- We make changes to the containers often, and recreating containers is not as fast as it should be (for example because a MariaDB dump needs to be restored).
- Creating a container implies some complex logic that does not easily fit a Dockerfile or Docker Compose (including, but not limited to, running multiple processes per container).

That said, every case is different. There are environments where these advantages do not apply, or bring a very small benefit. In those cases, the cost of adding some automation with Ansible, Puppet or similar software is probably not justified.

How to Deploy to Container from Orchestration Software

Suppose you want to manage containers configuration with Ansible.

At a first glance, the simplest way is to run Ansible in the host system. It will need to connect to the containers via SSH, so they need to expose the 22 port. But we have multiple containers, so we'll need to map the 22 port of each container to a different port in the host. This is hard to maintain and potentially insecure: in production you want to avoid exposing any container port to the host.

A better solution is to run Ansible itself in a container. The playbooks will be in a container volume, so we can access them from the host system to manage them more easily. The Ansible container will communicate with other containers using a container network, using the standard 22 port (or another port of your choice) for all containers.

Container Backup and Restoration

MariaDB databases in containers need backup and restore like their non-container equivalents.

Logical Backups

In this section, we will assume that the MariaDB container has been created as follows:

```
$ docker volume create mariadb_data
$ docker volume create mariadb_backup
$ docker run --rm \
  -v mariadb_data:/var/lib/mysql \
  -v mariadb_backup:/backup \
  mariadb \
  chown -R mysql:mysql /var/lib/mysql /backup
$ docker run -d --name mariadb \
  -v mariadb_data:/var/lib/mysql \
  -v mariadb_backup:/backup \
  -e MARIADB_ROOT_PASSWORD='MariaDB11!' \
  <mariadb-image>
```

Backup

mariadb-dump is in the Docker Official Image and can be used as follows:

```
$ docker exec mariadb \
  sh -c 'mariadb-dump --all-databases -u root -p"$MARIADB_ROOT_PASSWORD" > backup/db.sql'
```

Restoring Data from Dump Files

For restoring data, you can use the following `docker exec` command:

```
$ docker exec mariadb \
  sh -c 'mariadb -u root -p"$MARIADB_ROOT_PASSWORD" < backup/db.sql'
```

Physical Backups

mariadb-backup is in the Docker Official Image.

Backup

mariadb-backup can create a backup as follows:

To perform a backup using mariadb-backup, a second container is started that shares the original container's data directory. An additional volume for the backup needs to be included in the second backup instance. Authentication

against the MariaDB database instance is required to successfully complete the backup. In the example below, a `mysql@localhost` user is used with the MariaDB server's Unix socket shared with the backup container.

Note: Privileges listed here are for 10.5+. For an exact list, see mariadb-backup: Authentication and Privileges.

```
$ docker volume create mariadb_data
$ docker volume create mariadb_backup
$ docker run --rm \
  -v mariadb_data:/var/lib/mysql \
  -v mariadb_backup:/backup \
  mariadb \
  chown -R mysql:mysql /var/lib/mysql /backup
$ docker run -d --name mariadb \
  -v mariadb_data:/var/lib/mysql \
  -v mariadb_backup:/backup \
  -e MARIADB_ROOT_PASSWORD='MariaDB11!' \
  -e MARIADB_MYSQL_LOCALHOST_USER=1 \
  -e MARIADB_MYSQL_LOCALHOST_GRANTS='RELOAD, PROCESS, LOCK TABLES, BINLOG MONITOR' \
  <mariadb-image>
```

mariadb-backup will run as the `mysql` user in the container, so the permissions on `/backup` will need to ensure that it can be written to by this user:

```
$ docker exec --user mysql mariadb mariadb-backup --backup --target-dir=backup
```

Restore

These steps restore the backup made with mariadb-backup.

At some point before doing the restore, the backup needs to be prepared. The prepare must be done with the same MariaDB version that performed the backup. Perform the prepare like this:

```
$ docker run --rm \
  --name mariadb-restore \
  -v mariadb_backup:/backup \
  <mariadb-image> \
  mariadb-backup --prepare --target-dir=backup
```

Now that the image is prepared, start the container with both the data and the backup volumes and restore the backup. The data directory must be empty to perform this action:

```
$ docker volume create mariadb_restore
$ docker run --rm \
   -v mariadb_restore:/var/lib/mysql \
   --name mariadb-restore-change-permissions \
  <mariadb-image> \
  chown mysql: /var/lib/mysql
$ docker run --rm \
  --name mariadb-restore \
  -v mariadb_restore:/var/lib/mysql \
  -v mariadb_backup:/backup \
  --user mysql \
  <mariadb-image> \
  mariadb-backup --copy-back --target-dir=backup
```

With `mariadb_restore` volume containing the restored backup, start normally as this is an initialized data directory. At this point a later version of `<mariadb-image>` container can be used:

```
$ docker run -d --name mariadb \
  -v mariadb_restore:/var/lib/mysql \
  -e MARIADB_AUTO_UPGRADE=1 \
  -e MARIADB_ROOT_PASSWORD='MariaDB11!' \
  <mariadb-image>
```

On the environment variables here:

- MARIADB_AUTO_UPGRADE here in addition to upgrading the system tables ensures there is a healthcheck user.
- `MARIADB_ROOT_PASSWORD` is a convenience if any scripts, like logical backup above, use the environment variable. This environment variable is not strictly required.

For further information on mariadb-backup, see mariadb-backup Overview.

Container Security

When using containers in production, it is important to be aware of container security concerns.

Host System Security

Depending on the container runtime, containers may be running on the host system's kernel or a kernel shared with other containers. If this kernel has security bugs, those bugs are also present in the containers. Malicious containers may attempt to explain a kernel vulnerability to impact the confidentiality, integrity or availability of other containers.

In particular, Linux based containers have a container runtime that can use the following features:

- Namespaces, to isolate containers from each other and make sure that a container can't establish unauthorized connections to another container.
- Seccomp security profiles.
- Rootless operation in Docker, or Rootless Podman
- cgroups, to limit the resources (CPU, memory, IO) that each container can consume.

The administrators of a system should be particularly careful to upgrade the kernel whenever security bugs to these features are fixed.

It is important to note that when we upgrade the kernel, runC or Docker itself we cause downtime for all the containers running on the system.

Images Security

Containers are built from images. If security is a major concern, you should make sure that the images you use are secure.

If you want to be sure that you are pulling authentic images, you should only pull images signed with Docker Content Trust. Signing only ensure authenticity or origin, it doesn't dictate that entity is trustworthy.

Updated images should be used. An image usually downloads packages information at build time. If the image is not recently built, a newly created container will have old packages. Updating the packages on container creation and regularly re-updating them will ensure that the container uses packages with the most recent versions. Rebuilding an image often will reduce the time necessary to update the packages the first time.

Security bugs are usually important for a database server, so you don't want your version of MariaDB to contain known security bugs. But suppose you also have a bug in Docker, in runC, or in the kernel. A bug in a user-facing application may allow an attacker to exploit a bug in those lower level technologies. So, after gaining access to the

container, an attacker may gain access to the host system. This is why system administrators should keep both the host system and the software running in the containers updated.

Creating a Custom Container Image

OCI containers, frequently and incorrectly called Docker containers, are created from OCI images. An image contains software that can be launched, including the underlying system. A container is an instance of that software.

When we want to automate MariaDB, creating an image with MariaDB and the desired configuration, we may want to create an image by ourselves, which fulfils our needs.

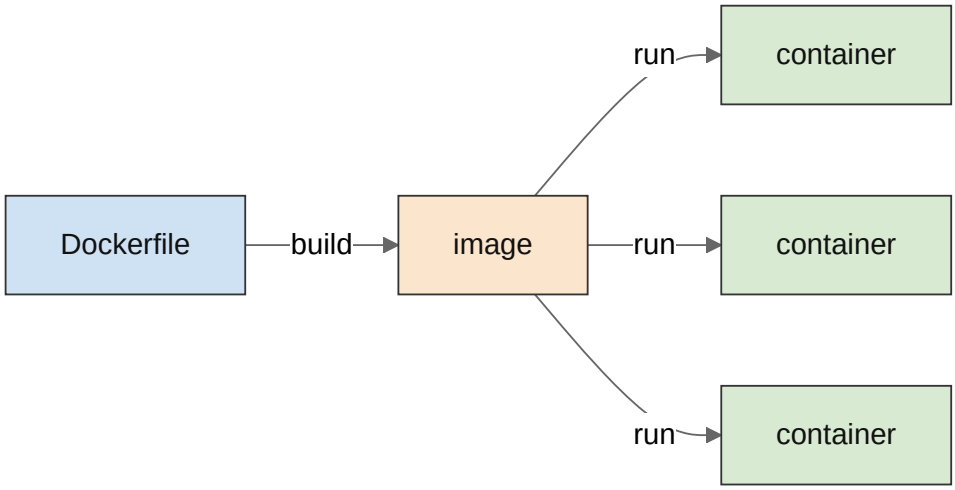
Images Architecture

One “source code” of an image is a Dockerfile. A Dockerfile is written in Docker specific language, and can be compiled into an image by the `docker` binary, using the `docker build` command. It can also be compiled by buildah using `buildah bud`.

Most images are based on another image. The base image is specified at the beginning of the Dockerfile, with the `FROM` directive. If the base image is not present in the local system, it is downloaded from the repository specified, or if not specified, from the default repository of the build program. This is often Docker Hub. For example, we can build a `mariadb-rocksdb:10.5` image starting from the `debian:13` image. In this way, we’ll have all the software included in a standard Debian image, and we’ll add MariaDB and its configuration upon that image.

All the following Dockerfile directives are compiled into a new Docker image, identified by an SHA256 string. Each of these images is based on the image compiled from the previous directive. A physical compiled image can serve as a base for any number of images. This mechanism saves a lot of disk space, download time and build time.

The following diagram shows the relationship between Dockerfiles, images and containers:



A Dockerfile is built into an image, which can then be run to create multiple containers.

Dockerfile Syntax

Here's a simple Dockerfile example:

```
FROM ubuntu:20.04

RUN apt-get update
RUN apt-get install -y mariadb-server

EXPOSE 3306

LABEL version="1.0"
LABEL description="MariaDB Server"

HEALTHCHECK --start-period=5m \
  CMD mariadb -e 'SELECT @@datadir;' || exit 1

CMD ["mariadbd"]
```

This example is not very good for practical purposes, but it shows what a Dockerfile looks like.

First, we declare that the base image to use is `ubuntu:20.04`.

Then we run some commands to install MariaDB from the Ubuntu default repositories and stop the MariaDB service.

We define some metadata about the image with `LABEL`. Any label is valid.

We declare that the port 3306 (MariaDB default port) should be exposed. However, this has no effect if the port is not exposed at container creation.

We also define a healthcheck. This is a command that is run to check if the container is healthy. If the return code is 0 the healthcheck succeeds, if it's 1 it fails. In the MariaDB specific case, we want to check that it's running and able to answer a simple query. This is better than just checking that MariaDB process is running, because MariaDB could be running but unable to respond, for example because max_connections was reached or data si corrupted. We read a system variable, because we should not assume that any user-created table exists. We also specify `--start-period` to allow some time for MariaDB to start, keeping in mind that restarting it may take some time if some data is corrupted. Note that there can be only one healthcheck: if the command is specified multiple times, only the last occurrence will take effect.

Finally, we start the container command: mariadbd. This command is run when a container based on this image starts. When the process stops or crashes, the container will immediately stop.

Note that, in a container, we normally run mariadbd directly or in an entrypoint script `exec mariadbd`, rather than running mysqld_safe or running MariaDB as a service. Containers restart can be handled by the container service. See automatic restart.

See the documentation links below to learn the syntax allowed in a Dockerfile.

Using Variables

It is possible to use variables in a Dockerfile. This allows us, for example, to install different packages, install different versions of a package, or configure software differently depending on how variables are set, without modifying the Dockerfile itself.

To use a variable, we can do something like this:

```
FROM ubuntu:20.04

ARG MARIADB_CONFIG_FILE

...

ENTRYPOINT mariadbd --defaults-file=$MARIADB_CONFIG_FILE
```

Here `ARG` is used after the `FROM` directive, thus the variable cannot be used in `FROM`. It is also possible to declare a variable before `FROM`, so we can use a variable to select the base image to use or its tag, but in this case the variable cannot be used after the `FROM` directive, unless `ARG` is redeclared after the `FROM`. Here is an example:

```
ARG UBUNTU_VERSION
FROM ubuntu:$UBUNTU_VERSION

# Uncomment for the build error to be avoided
# ARG UBUNTU_VERSION

# But this will cause a build error:
RUN echo 'Ubuntu version: $UBUNTU_VERSION' > /var/build_log
```

We'll have to assign variables a value when we build the Dockerfile, in this way:

```
docker build --build-arg UBUNTU_VERSION=20.04 .
```

Note that Dockerfile variables are just placeholders for values. Dockerfiles do not support assignment, conditionals or loops.

Versioning and Deploying Images

Dockerfiles are normally versioned, as well as the files that are copied to the images.

Once an image is built, it can be pushed to a container registry. Whenever an image is needed on a host to start containers from it, it is pulled from the registry.

Container registries

A default container registry for OCI images is Docker Hub. It contains Docker Official Images maintained by the Docker Library team and the community. Any individual or organization can open an account and push images to Docker Hub. Most Docker images are open source: the Dockerfiles and the needed files to build the images are usually on GitHub.

It is also possible to setup a self-hosted registry. Images can be pushed to that registry and pulled from it, instead of using Docker Hub. If the registry is not publicly accessible, it can be used to store images used by the organization without making them publicly available.

But a self-hosted registry can also be useful for open source images: if an image is available on Docker Hub and also on a self-hosted registry, in case Docker Hub is down or not reachable, it will still be possible to pull images.

Choosing Image Names and Tags

The names of images developed by the community follow this schema:

```
repository/maintainer/technology
```

It doesn't matter if the maintainer is an individual or an organization. For images available on Docker Hub, the maintainer is the name of a Docker Hub account.

Official images maintained by the Docker Library maintainers have the implicit name of `library` filled in by the container fetching tool. For example, the official MariaDB image is called `mariadb` which is an alias for `docker.io/library/mariadb`.

All images have a tag, which identifies the version or the variant of an image. For example, all MariaDB versions available on Docker are used as image tags. MariaDB 10.11 is called `mariadb:10.11`.

By conversion, tags form a hierarchy. So for example, there is a `10.1.1` tag whose meaning will not change over time. `10.5` will always identify the latest stable version in the 10.5 branch. For some time it was `10.5.1`, then it became `10.5.2`, and so on.

When we pull an image without specifying a tag (ie, `docker pull mariadb`), we are implicitly requiring the image with the `latest` tag. This is even more mutable: at different periods of time, it pointed to the latest `10.0` version, to the latest `10.1` version, and so on.

In production, it is always better to know for sure which version we are installing. Therefore it is better to specify a tag whose meaning won't change over time, like `10.5.21`. To keep to a latest LTS version, the `lts` can be used.

Pushing and Pulling Images

To pull an image from Docker Hub or a self-hosted registry, we use the `docker pull` command. For example:

```
docker pull mariadb:10.5
```

This command downloads the specified image if it is not already present in the system, or if the local version is not up to date.

After modifying a Dockerfile, we can build an image in this way:

```
docker build .
```

This step can be automated by services like Docker Hub and GitHub. Check those service's documentation to find out how this feature works.

Once an image is created, it can be pushed to a registry. We can do it in this way:

```
docker push <image_name>:<tag>
```

Docker Content Trust

Docker has a feature called Docker Content Trust (DCT). It is a system used to digitally sign images, based on PEM keys. For environments where security is a major concern, it is important to sign images before pushing them. This can be done with both Docker Hub and self-hosted registries.

Good Practices and Caveats

As mentioned, a Dockerfile is built by creating a new image for each directive that follows `FROM`. This leads to some considerations.

- Sometimes it can be a good idea to run several shell commands in a single `RUN` directive to avoid creating images that are not useful.
- Modifying a directive means that all subsequent directives also need to be rebuilt. When possible, directives that are expected to change often should follow directives that will change seldom.
- Directives like `LABEL` or `EXPOSE` should be placed close to the end of Dockerfiles. In this way they will be rebuilt often, but this operation is cheap. On the other side, changing a label should not trigger a long rebuild process.
- Variables should be used to avoid Dockerfiles proliferation. But if a variable is used, changing its value should be tested. So, be sure not to use variables without a good reason.

- Writing logic into a Dockerfile is impossible or very hard. Call shell scripts instead, and write your logic into them. For example, in a shell script it is easy to perform a certain operation only if a variable is set to a certain value.
- If you need MariaDB containers with different configurations or different sets of plugins, use the method explained above. Do not create several Dockerfiles, with different tags, for each desired configuration or plugin set. This may lead to undesired code duplication and increased maintenance costs.

Deploy MariaDB Enterprise Server with Docker

MariaDB Corporation provides Docker images for MariaDB Enterprise Server in the MariaDB Enterprise Docker Registry.

Docker provides multiple benefits:

- Docker is an open platform for developing, shipping, and running applications that allows you to separate your applications from your infrastructure.
- Docker images are portable. A Docker image can be deployed in a Docker container on any system using the Docker platform, regardless of the host operating system.
- Docker containers are isolated from the host operating system and from other Docker containers.

If you want to deploy MariaDB Enterprise Server without Docker, alternative deployment methods are available.

Use Cases

MariaDB Enterprise Server can be deployed with Docker to support use cases that require software to be rapidly deployed on existing infrastructure, such as:

- Continuously create and destroy automated testing environments as part of a continuous integration (CI) pipeline
- Create a small test environment on a local workstation
- Create multiple isolated test environments on the same host
- Deployment alongside related containers using Docker Compose

Compatibility

The following products and versions can be deployed using the MariaDB Enterprise Docker Registry:

- MariaDB Enterprise Server 11.8
- MariaDB Enterprise Server 11.4
- MariaDB Enterprise Server 10.6

For details about which storage engines and plugins are supported in the images for each version, see "MariaDB Enterprise Docker Registry".

Deploy Enterprise Server in a Docker Container

To deploy MariaDB Enterprise Server in a Docker container, follow the instructions below.

Step 1: Retrieve Customer Download Token

MariaDB Corporation requires customers to authenticate when logging in to the MariaDB Enterprise Docker Registry. A customer-specific Customer Download Token must be provided as the password.

Customer Download Tokens are available through the MariaDB Customer Portal.

To retrieve the customer download token for your account:

1. Navigate to the Customer Download Token at the MariaDB Customer Portal.
2. Log in using your MariaDB ID.
3. Copy the Customer Download Token to use as the password when logging in to the MariaDB Enterprise Docker Registry.

Step 2: Log In to Docker Registry

Log in to the MariaDB Enterprise Docker Registry by executing `docker login`:

```
$ docker login docker.mariadb.com
```

When prompted, enter the login details:

- As the user name, enter the email address associated with your MariaDB ID.
- As the password, enter your Customer Download Token.

The login details will be saved.

Confirm the login details were saved by checking the /.docker/config.json file for a JSON object named "docker.mariadb.com" inside an "auths" parent JSON object:

```
$ cat ~/.docker/config.json
```

```
{
   "auths": {
      "docker.mariadb.com": {
         "auth": "<auth_hash>"
      }
   }
}
```

Step 3: Choose an Image Tag

The `enterprise-server` repository in the MariaDB Enterprise Docker Registry contains images for different MariaDB Enterprise Server releases using specific tags. Before continuing, you will need to decide which tag to use.

To deploy a container using the most recent image for the latest MariaDB Enterprise Server release series (currently 11.8), use the `latest` tag.

For additional information, see "MariaDB Enterprise Docker Registry: Tags".

Step 4: Pull Docker Image

Pull the Docker image with the chosen tag by executing `docker pull`:

```
docker pull docker.mariadb.com/enterprise-server:latest
```

```
latest: Pulling from enterprise-server
5d87d5506868: Pull complete
Digest: sha256:68795ca747901e3402e30dab71d6d8bc72bce727db3b9e4888979468be77d250
Status: Downloaded newer image for docker.mariadb.com/enterprise-server:latest
docker.mariadb.com/enterprise-server:latest
```

Confirm the Docker image has been pulled by executing `docker images`:

```
docker images \
   --filter=reference='docker.mariadb.com/enterprise-server'
```

```
REPOSITORY                            TAG       IMAGE ID       CREATED        SIZE
docker.mariadb.com/enterprise-server   latest    dd17291aa340   3 months ago   451MB
```

Step 5: Create a Container

Create a container using the pulled Docker image by executing `docker run`:

```
docker run --detach \
   --name mariadb-es-latest \
   --env MARIADB_ROOT_PASSWORD='YourSecurePassword123!' \
   --publish '3307:3306/tcp' \
   docker.mariadb.com/enterprise-server:latest \
   --log-bin=mariadb-bin \
   <other mariadbd command-line options>
```

```
3082ab69e565be21c6157bb5a3d8c849ec03a2c51576778ac417a8a3aa9e7537
```

- Configure the container and set the root password using environment variables by setting the `--env` command-line option.
- Configure TCP port bindings for the container by setting the `--publish` or `--publish-all` command-line options.
- Configure MariaDB Enterprise Server by setting mariadbd command-line options.

Confirm the container is running by executing `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:latest'
```

```
CONTAINER ID   IMAGE                                          COMMAND                  CREATED
STATUS                     PORTS      NAMES
3082ab69e565   docker.mariadb.com/enterprise-server:latest   "/es-entrypoint.sh -…"   12 seconds ago   Up
11 seconds              3306/tcp   mariadb-es-latest
```

By default, Docker uses Docker bridge networking for new containers. For details on how to use host networking for new containers, see “Create a Container with Host Networking”.

Step 6: Connect to Container

Connect to the container by executing MariaDB Client on the container using docker exec:

```
docker exec --interactive --tty \
   mariadb-es-latest \
   mariadb \
   --user=root \
   --password
```

Confirm the container is using the correct version of MariaDB Enterprise Server by querying the version system variable with the SHOW GLOBAL VARIABLES statement:

```
SHOW GLOBAL VARIABLES
   LIKE 'version'\G
```

```
*************************** 1. row ***************************
Variable_name: version
        Value: 11.8.3-1-MariaDB-enterprise-log
```

Exit the container using `exit`:

```
exit
```

```
Bye
```

Step 7: Stop Container

Stop a Docker container using `docker stop`:

```
docker stop mariadb-es-latest
```

```
mariadb-es-latest
```

Confirm the container is stopped by executing `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:latest'
```

```
CONTAINER ID   IMAGE                                          COMMAND                  CREATED
STATUS                            PORTS       NAMES
3082ab69e565   docker.mariadb.com/enterprise-server:latest   "/es-entrypoint.sh -…"   2 minutes ago
Exited (143) About a minute ago               mariadb-es-latest
```

Step 8: Remove Container

Remove a Docker container using `docker rm`:

```
docker rm mariadb-es-latest
```

```
mariadb-es-latest
```

Confirm the container is removed by executing docker ps:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:latest'
```

```
CONTAINER ID   IMAGE     COMMAND   CREATED   STATUS    PORTS     NAMES
```

MariaDB Enterprise Docker Registry for MariaDB Enterprise Server

MariaDB Corporation provides the MariaDB Enterprise Docker Registry. The MariaDB Enterprise Docker Registry provides Docker images for MariaDB Enterprise Server.

This page contains reference material for the MariaDB Enterprise Docker Registry.

The reference material on this page applies to MariaDB Enterprise Server 10.6 and later.

Details

Docker is an open platform for developing, shipping, and running applications that allows you to separate your applications from your infrastructure.

MariaDB Corporation provides the MariaDB Enterprise Docker Registry. The MariaDB Enterprise Docker Registry provides Docker images for MariaDB Enterprise Server.

For examples that show how to use the Docker images in the MariaDB Enterprise Docker Registry for MariaDB Enterprise Server, see Examples.

Other details are listed in the sections below.

- Versions
- Storage Engines
- Plugins
- Repositories
- Tags

Versions

The MariaDB Enterprise Docker Registry provides Docker images for **MariaDB Enterprise Server 10.6 and later**.

Storage Engines

The Docker images for MariaDB Enterprise Server include all storage engines that are installed with MariaDB Enterprise Server by default. The following storage engines are currently included:

- Aria
- CSV
- InnoDB
- MEMORY
- MRG_MYISAM
- MyISAM

You can check which storage engines are installed by connecting to the Docker container and executing the SHOW ENGINES statement.

Plugins

The Docker images for MariaDB Enterprise Server include all plugins that are installed with MariaDB Enterprise Server by default.

You can check which plugins are installed by connecting to the Docker container and executing the SHOW PLUGINS statement.

The container contains shared libraries for additional plugins that can be installed with the INSTALL SONAME statement or the –plugin-load-add command-line option. You can check which plugins are available by querying the information_schema.ALL_PLUGINS table:

```
SELECT PLUGIN_NAME, PLUGIN_VERSION, PLUGIN_LIBRARY
FROM information_schema.ALL_PLUGINS
WHERE PLUGIN_STATUS = 'NOT INSTALLED';
```

```
+---------------------------+----------------+------------------------+
| PLUGIN_NAME               | PLUGIN_VERSION | PLUGIN_LIBRARY         |
+---------------------------+----------------+------------------------+
| pam                       | 1.0            | auth_pam_v1.so         |
| LOCALES                   | 1.0            | locales.so             |
| BLACKHOLE                 | 1.0            | ha_blackhole.so        |
| SQL_ERROR_LOG             | 1.0            | sql_errlog.so          |
| METADATA_LOCK_INFO        | 0.1            | metadata_lock_info.so  |
| pam                       | 2.0            | auth_pam.so            |
| SERVER_AUDIT              | 1.4            | server_audit.so        |
| file_key_management       | 1.0            | file_key_management.so |
| QUERY_RESPONSE_TIME       | 1.0            | query_response_time.so |
| QUERY_RESPONSE_TIME_AUDIT | 1.0            | query_response_time.so |
+---------------------------+----------------+------------------------+
```

Repositories

The MariaDB Enterprise Docker Registry contains a single repository, which provides images for MariaDB Enterprise Server:

- `enterprise-server`

Tags

The `enterprise-server` repository in the MariaDB Enterprise Docker Registry contains images for different MariaDB Enterprise Server releases using specific tags:

Type of release?	Tags	Description
Latest release series		This tag refers to the most recent image for the latest MariaDB Enterprise Server release series, which is currently MariaDB Enterprise Server 11.8.
Specific release series		These tags refer to the images for the most recent minor release of each specific MariaDB Enterprise Server release series.
Specific minor release		These tags refer to images for specific MariaDB Enterprise Server minor releases. The listed tags are examples of minor releases. For a full list of minor releases, see MariaDB Enterprise Server All Releases.

Examples

- Connect to Container with Docker Bridge Networking
- Connect to Container with Host Networking
- Create a Container with Docker Bridge Networking
- Create a Container with Host Networking
- Environment Variables
- Inspect Container
- Log In to Docker Registry
- Obtain a Shell in Container

- Pull Docker Image
- Remove Container
- Stop Container
- View Container Logs

Connect to Container with Docker Bridge Networking

To connect to a Docker container that uses Docker bridge networking, execute MariaDB Client on the container using `docker exec`:

```
docker exec --interactive --tty \
   mariadb-es-11.4 \
   mariadb \
   --user=root \
   --password
```

To confirm the client is connected to the Docker container and the container is using the correct version of MariaDB Enterprise Server, query the version system variable with the SHOW GLOBAL VARIABLES statement:

```
SHOW GLOBAL VARIABLES
   LIKE 'version'\G
```

```
*************************** 1. row ***************************
Variable_name: version
        Value: 11.4.5-3-MariaDB-enterprise-log
```

To exit the container, use `exit`:

```
exit
```

```
Bye
```

The example above shows how to connect to a Docker container using MariaDB Client on the container, but you can also connect using MariaDB Client on the host using TCP/IP. You can inspect the Docker container to find the container's IP address and TCP port bindings.

Connect to Container with Host Networking

To connect to a Docker container that uses host networking, execute MariaDB Client on the host node and specify the host's IP address and the container's port:

```
mariadb --host=192.0.2.1 \
   --port=3307 \
   --user=root \
   --password
```

To confirm the client is connected to the Docker container and the container is using the correct version of MariaDB Enterprise Server, query the version system variable with the SHOW GLOBAL VARIABLES statement:

```
SHOW GLOBAL VARIABLES
   LIKE 'version'\G
```

```
*************************** 1. row ***************************
Variable_name: version
        Value: 11.8.3-1-MariaDB-enterprise-log
```

To exit the container, use `exit`:

```
exit
```

```
Bye
```

Create a Container with Docker Bridge Networking

By default, Docker containers use Docker bridge networking. To make connecting to the container easier, Docker can use port bindings to publish the container's TCP ports to the host.

To create a Docker container using Docker bridge networking, execute `docker run`:

```
docker run --detach \
   --name mariadb-es-11.8 \
   --env MARIADB_ROOT_PASSWORD='Password123!' \
   --publish '3307:3306/tcp' \
   docker.mariadb.com/enterprise-server:11.8 \
   --log-bin=mariadb-bin \
   <other mariadbd command-line options>
```

```
3082ab69e565be21c6157bb5a3d8c849ec03a2c51576778ac417a8a3aa9e7537
```

- Configure the container using environment variables by setting the `--env` command-line option.
- Configure TCP port bindings for the container by setting the `--publish` or `--publish-all` command-line options.
- Configure MariaDB Enterprise Server by setting mariadbd command-line options.

To confirm the Docker container is running, execute `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:11.8'
```

```
CONTAINER ID   IMAGE                                          COMMAND                  CREATED
STATUS                     PORTS      NAMES
3082ab69e565   docker.mariadb.com/enterprise-server:11.8   "/es-entrypoint.sh -…"   12 seconds ago   Up
11 seconds                3306/tcp   mariadb-es-11.8
```

Create a Container with Host Networking

A Docker container can be configured to use the host operating system's network.

To create a Docker container using host networking, execute `docker run` and specify the `--network host` option:

```
docker run --detach \
   --network host \
   --name mariadb-es-11.8 \
   --env MARIADB_ROOT_PASSWORD='Password123!' \
   docker.mariadb.com/enterprise-server:11.8 \
   --port=3307 \
   --log-bin=mariadb-bin \
   <other mariadbd command-line options>
```

```
3082ab69e565be21c6157bb5a3d8c849ec03a2c51576778ac417a8a3aa9e7537
```

- Configure the container using environment variables by setting the `--env` command-line option.
- Configure the port for MariaDB Enterprise Server by setting the –port command-line option.
- Configure MariaDB Enterprise Server by setting mariadbd command-line options.

To confirm the Docker container is running, execute `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:11.8'
```

Environment Variables

A Docker container can be configured to perform the following tasks using environment variables:

- Create a custom database
- Create a custom database user account with a custom password
- Initialize the timezone tables
- Set the host for the `root` database user
- Set the password for the `root` database user

The following table contains details about the environment variables that are supported:

Environment Variable	Description	Default	Allowed Values
`MARIADB_DATABASE`	When the `MARIADB_DATABASE` environment variable is set to a valid database name, create the specified database if it does not already exist.	No default	Any valid database name
`MARIADB_INITDB_SKIP_TZINFO`	By default, the entrypoint script automatically loads the timezone data needed for the `CONVERT_TZ()` function. If it is not needed, any non-empty value disables timezone loading.	No default	
`MARIADB_PASSWORD`	When the `MARIADB_USER` and `MARIADB_PASSWORD` environment variables are both set, create a user account with the specified user name and password.	No default	Any valid password
`MARIADB_ROOT_HOST`	When the `MARIADB_ROOT_HOST` environment variable is set to a valid hostname, the `root` user account will be restricted to logins from that hostname.	`%`	Any valid hostname
`MARIADB_ROOT_PASSWORD`	When the `MARIADB_ROOT_PASSWORD` environment variable is set to `RANDOM`, a random password is generated for the `root` user account. When the `MARIADB_ROOT_PASSWORD` environment variable is set to `EMPTY`, the `root` user account uses an empty password. When the `MARIADB_ROOT_PASSWORD` environment variable is set to a valid password, the `root` user account uses the specified password.	No default	
`MARIADB_USER`	When the `MARIADB_USER` and `MARIADB_PASSWORD` environment variables are both set, create a user account with the specified user name and password.	No default	Any valid user name
`MARIADB_UNIX_SOCKET_AUTHENTICATION`	When set to 1, enables Unix socket-based authentication for the root user, allowing passwordless access when connecting locally as the mysql system user. This option is mutually exclusive with all MARIADB_ROOT_PASSWORD* variables.	Empty	1,0
`SKIP_INIT_WSREP_OFF`	By default, the temporary server used for initialization is started with Galera Cluster replication explicitly turned off (–wsrep_on=OFF). If this variable is set, that flag is omitted, allowing the temporary server to start with wsrep enabled.	No default	Any non-empty value

To create a Docker container using environment variables, execute `docker run`, environment variables and specify each environment variable using the `--env` option:

```
docker run --detach \
   --network host \
   --name mariadb-es-11.8 \
   --env MARIADB_ROOT_PASSWORD='Password123!' \
   docker.mariadb.com/enterprise-server:11.8
```

```
3082ab69e565be21c6157bb5a3d8c849ec03a2c51576778ac417a8a3aa9e7537
```

Inspect Container

A Docker contained can be inspected to find out internal details about the container, such as the following details:

- IP addresses
- MAC addresses
- Port bindings

To inspect all internal details about a Docker container, execute `docker inspect`:

```
docker inspect mariadb-es-11.8
```

```
[
    {
        "Id": "d784a193ad828cbd3db10dfbef3e3b7274465fa587453c3f6e2e27703b361173",
        "Created": "2021-10-13T20:25:04.994759266Z",
        "Path": "docker-entrypoint.sh",
        "Args": [
            "--log-bin=mariadb-bin"
        ],
        "State": {
            "Status": "running",
            "Running": true,
            "Paused": false,
            "Restarting": false,
            "OOMKilled": false,
            "Dead": false,
            "Pid": 33714,
            "ExitCode": 0,
            "Error": "",
            "StartedAt": "2021-10-13T20:25:05.32049779Z",
            "FinishedAt": "0001-01-01T00:00:00Z"
        },
        ..
    }
]
```

To inspect a specific internal detail about a Docker container, execute `docker inspect` and specify a filter using the `--format` option. Some examples are shown below.

To inspect the container's IP address:

```
docker inspect \
   --format='{{range .NetworkSettings.Networks}}{{.IPAddress}}{{end}}' \
   mariadb-es-11.8
```

```
172.17.0.3
```

To inspect the container's TCP port bindings:

```
docker inspect \
   --format='{{range $p, $conf := .NetworkSettings.Ports}}Container port: {{$p}} -> Host port: {{(index
$conf 0).HostPort}} {{end}}' \
   mariadb-es-11.8
```

```
Container port: 3306/tcp -> Host port: 3307
```

Log In to Docker Registry

To log in to the MariaDB Enterprise Docker Registry, execute `docker login`:

```
docker login docker.mariadb.com
```

When prompted, enter the login details:

- As the user name, enter the email address associated with your MariaDB ID.
- As the password, enter your Customer Download Token.

The login details will be saved.

To confirm the login details were saved, check the `~/.docker/config.json` file for a JSON object named `"docker.mariadb.com"` inside an `"auths"` parent JSON object:

```
cat ~/.docker/config.json
{
   "auths": {
      "docker.mariadb.com": {
         "auth": "<auth_hash>"
      }
   }
}
```

Obtain a Shell in Container

To obtain a shell in the Docker container, execute the shell on the container using `docker exec`:

```
docker exec --interactive --tty \
   mariadb-es-11.8 \
   bash
```

Pull Docker Image

To pull a Docker image with the appropriate tag, execute `docker pull`:

```
docker pull docker.mariadb.com/enterprise-server:11.8
```

```
11.8: Pulling from enterprise-server
5d87d5506868: Pull complete
Digest: sha256:68795ca747901e3402e30dab71d6d8bc72bce727db3b9e4888979468be77d250
Status: Downloaded newer image for docker.mariadb.com/enterprise-server:11.8
docker.mariadb.com/enterprise-server:11.8
```

To confirm the Docker image has been pulled, execute `docker images`:

```
docker images \
   --filter=reference='docker.mariadb.com/enterprise-server'
```

```
REPOSITORY                            TAG       IMAGE ID       CREATED        SIZE
docker.mariadb.com/enterprise-server   11.8      dd17291aa340   3 months ago   451MB
```

Remove Container

To remove a Docker container, execute `docker rm`:

```
docker rm mariadb-es-11.8
```

```
mariadb-es-11.8
```

To confirm the container is removed, execute `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:11.8'
```

```
CONTAINER ID   IMAGE     COMMAND   CREATED   STATUS    PORTS     NAMES
```

Stop Container

To stop a Docker container, execute `docker stop`:

```
docker stop mariadb-es-11.8
```

```
mariadb-es-11.8
```

To confirm the container is stopped, execute `docker ps`:

```
docker ps \
   --all \
   --filter ancestor='docker.mariadb.com/enterprise-server:11.8'
```

```
CONTAINER ID   IMAGE                                          COMMAND                  CREATED
STATUS                             PORTS       NAMES
3082ab69e565   docker.mariadb.com/enterprise-server:11.8   "/es-entrypoint.sh -…"   2 minutes ago
Exited (143) About a minute ago               mariadb-es-11.8
```

View Container Logs

To view the logs in the Docker container, execute `docker logs`:

```
docker logs mariadb-es-11.8
```

This page is licensed: CC BY-SA / Gnu FDL

Docker and AWS EC2

This process shows how to deploy MariaDB in a Docker container running on an EC2 instance. First we'll create the EC2 VM, then we'll deploy Docker to it. After that, we'll pull the MariaDB Docker image which we'll use to create a running container with a MariaDB instance. Finally, we'll load a sample database into the MariaDB instance.

Create a VM in AWS EC2

1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.
2. Login to AWS, navigate to EC2 service home
3. Choose Region for EC2 in the upper right corner of the console
4. Launch (1) Instance, giving instance a name (e.g. mrdb-ubuntu-docker-use1) and create or reuse a key pair
5. Choose Ubuntu 22.04 or similar free tier instance

6. Choose hardware, t2.micro or similar free tier instance
7. Create Key Pair with name (e.g. mrdb-docker-aws-pk.pem if using openSSH at the command line, or mrdb-docker-aws-pk..ppk for use with programs like PuTTY.)
8. Create or select a security group where SSH is allowed from anywhere 0.0.0.0/0. If you'd like to make this more secure, it can be restricted to a specific IP address or CIDR block.

```
{{aws-firewall}}
```

10. Accept remaining instance creation defaults and click "launch instance".
11. Save the *.pem or *.ppk keyfile on your local hard drive when prompted. You will need it later. If you're on Linux, don't forget to change permissions on the downloaded *.pem / *.ppk key file:

```
$ chmod 400 mrdb-docker-pk.pem
```

12. Click into the instance summary (EC2 > Instances > Instance ID) and click on the "security" tab towards the bottom.

```
{{security-group}}
```

13. In the relevant security group for your instance, Create an inbound rule so that TCP port 3306 is open, allowing external connections to Maria DB (like your local command line client for MariaDB). Double check that port 22 is open while you're there for SSH.

Install Docker on the EC2 VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

14. Back in the instance summary (EC2 > Instances > Instance ID), copy the public IP (e.g. ww.xx.yyy.zzz)

```
{{aws-instance-ip}}
```

15. Open terminal window, navigate to the directory with private key (*.pem or *.ppk) file and start a SSH remote shell session by typing:

```
$ ssh -i mrdb-docker-pk.pem ubuntu@ww.xx.yyy.zzz
```

(switch ww.xx.yyy.zzz for your IP address from step 14).

16. Are you sure you want to continue connecting (yes/no/[fingerprint])?
    Say yes
17. Escalate to root

```
$ sudo su
```

18. Install Docker

```
$ curl -fsSL https://get.docker.com | sudo sh
```

Pull the Mariadb Docker Image and Create the Container

19. Pull MariaDB Docker image

```
$ docker pull mariadb:lts
```

20. Start MDRB docker process at your terminal / command line

```
$ docker run --detach --name mariadb-docker -v \Users\YouUID\Documents\YourDirName:/var/lib/mysql:Z -p
3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts
```

To ensure persistent storage, use the `-v` flag to mount your chosen directory as `/var/lib/mysql`. For Windows, represent file paths like `C:\Users\YourUID\Documents\YourDirName` accordingly. On Linux, use absolute file paths. Always replace the root password with a secure one, especially outside of development environments.

21. Shell into container

```
$ docker exec -it mariadb-docker bash
```

22. Login to MRDB inside container using the root password specified in step 20.

```
$ mariadb -pyoursecurepassword
```

23. Setup admin account with permission for remote connection, configure access control

```
MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';

MariaDB [(none)]> GRANT ALL ON *.* to 'admin'@'%' WITH GRANT OPTION;

MariaDB [(none)]> SHOW GRANTS FOR admin;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

24. Setup service account for your app with permission for remote connection, configure access control

```
MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';

MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON *.* to 'yourappname'@'%';

MariaDB [(none)]> SHOW GRANTS FOR yourappname;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

25. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

Open a new terminal window (not your SSH session) and navigate to the directory containing your database creation script, for example, `init.sql`. Then, enter the command:

```
$ mariadb --host=ww.xx.yyy.zzz --port=3306 --user=admin --password=admin -e “SOURCE init.sql”
```

(switch ww.xx.yyy.zzz for your IP address from step 14).

Docker and Google Cloud

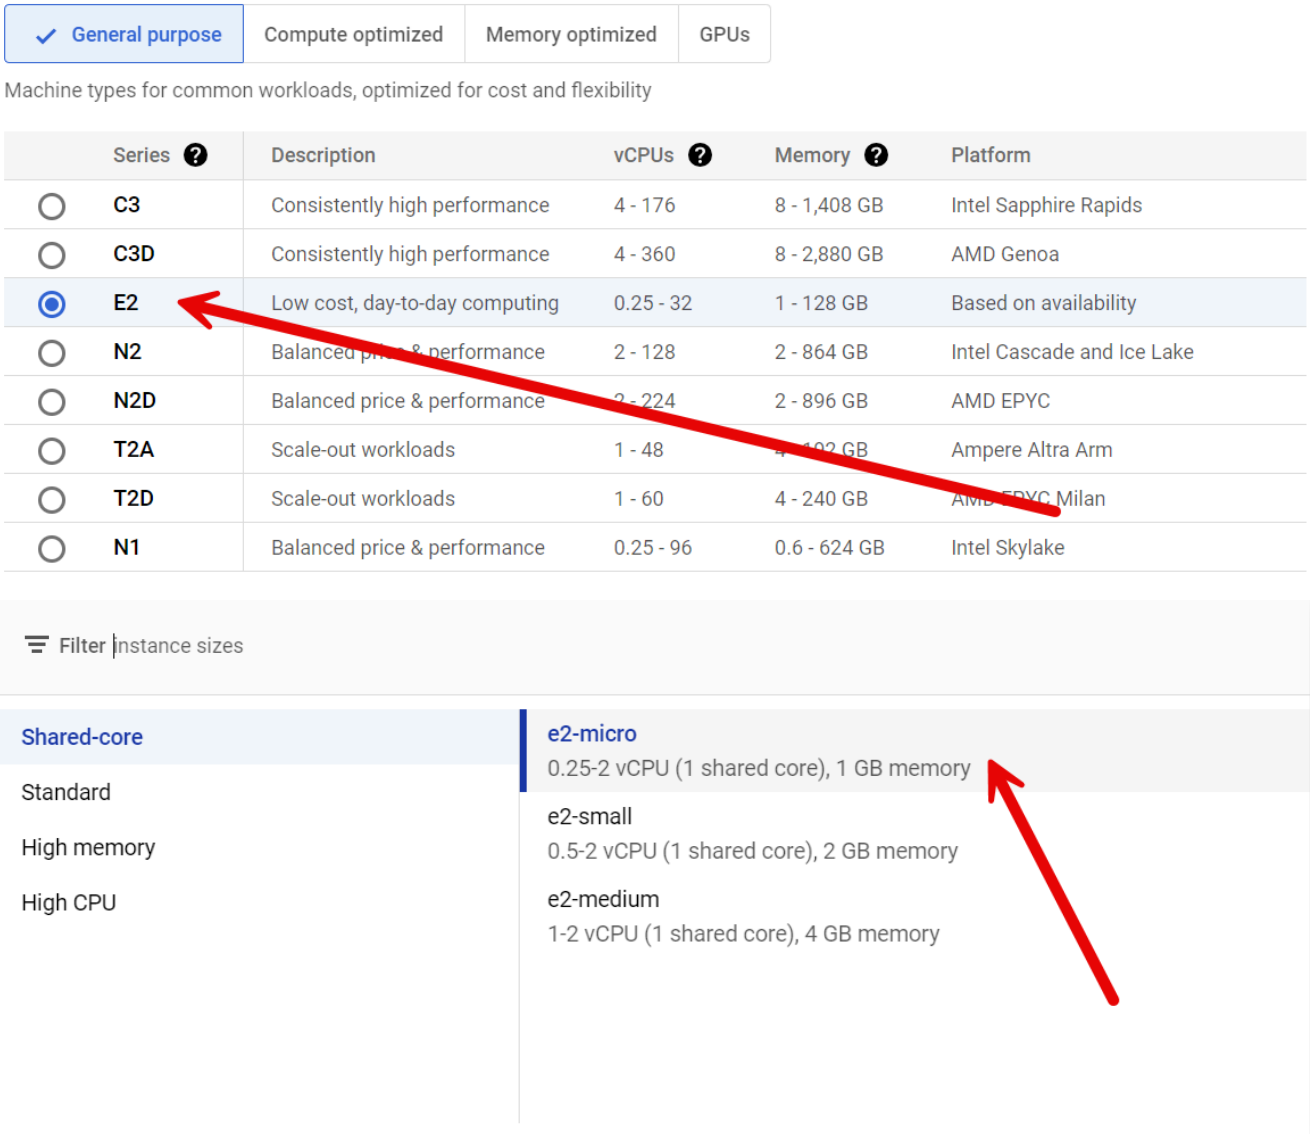
This process shows how to deploy MariaDB in a Docker container running on an GCE instance. First we’ll create the GCE VM, then we’ll deploy Docker to it. After that, we’ll pull the MariaDB Docker image which we’ll use to create a running container with a MariaDB instance. Finally, we’ll load a sample database into the MariaDB instance.

Create a VM in Google Cloud Compute Engine

1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.
2. Login to Google Cloud, navigate to VM instances

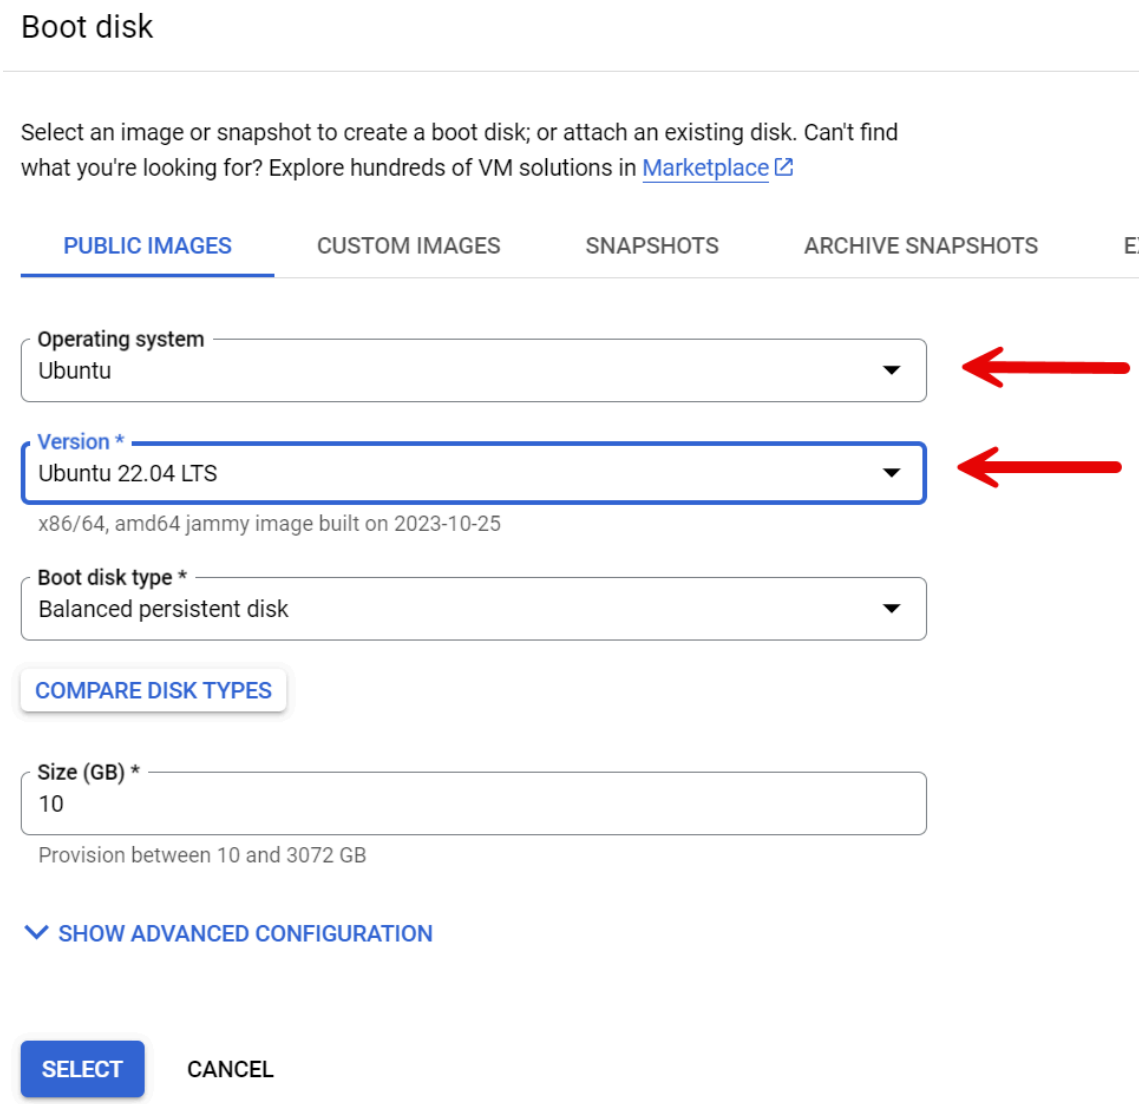
3. Enable Compute Engine API if you haven't already.
4. Click create instance, give instance a name (e.g. mrdb-ubuntu-docker-use1b), choose a region and zone.
5. Machine configuration: Choose general-purpose / E2 micro

Machine configuration



6. Boot Disk > Change

Switch the operating system to a modern Ubuntu release x86/64 CPU architecture, or similar free tier offering.



7. Create a firewall rule in the Firewall Policies section of the console. After naming it, change the targets, add 0.0.0.0/0 as a source IP range, and open TCP port 3306. Then Click create.

Direction of traffic

- (•) Ingress
- ( ) Egress

Action on match

- (•) Allow
- ( ) Deny

Targets
All instances in the network

Source filter
IPv4 ranges

Source IPv4 ranges *
0.0.0.0/0

Second source filter
None

Destination filter
None

Protocols and ports

- ( ) Allow all
- (•) Specified protocols and ports

[x] TCP

Ports
3306

E.g. 20, 50-60

[ ] UDP

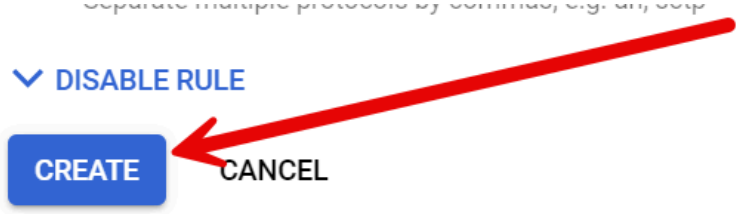
Ports

E.g. all

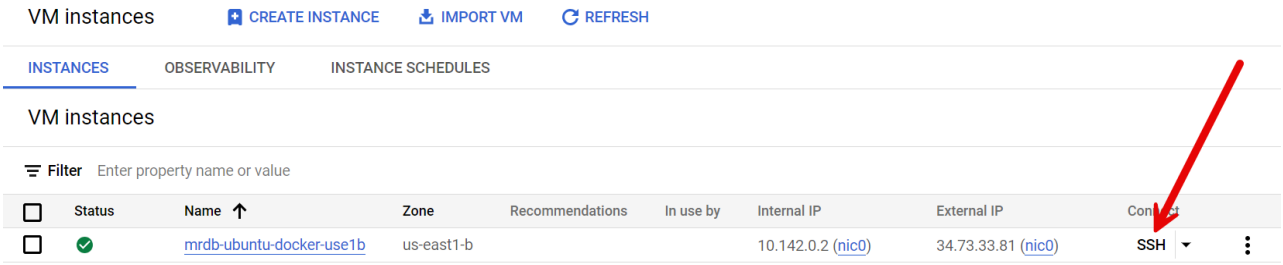
[ ] Other

Protocols

Separate multiple protocols by commas, e.g. ah, sctp



8. Connect using Google Cloud's built in browser SSH. Accept all prompts for authorization.



Install Docker on the GCE VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

9. Escalate to root Escalate to root

```
$ sudo su
```

10. Install Docker

```
$ curl -fsSL get.docker.com | sudo sh
```

11. Pull Docker image

```
$ docker pull mariadb:lts
```

12. Start MDRB docker process at your terminal / command line.

```
$ docker run --detach --name mariadb-docker -v \Users\YouUID\Documents\YourDirName:/var/lib/mysql:Z -p
3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts
```

Mounting a Directory for Persistent MySQL Storage

When using the `-v` flag to mount a directory as `/var/lib/mysql`, you ensure that your MySQL data is stored persistently.

File Path Instructions:

- **Windows**: Use a file path format similar to `C:\Users\YourUsername\Documents\YourDirectory`.
- **Linux**: Always use absolute paths instead of relative ones.

> **Important:**
>
> **Root Password**: Replace the default root password with a strong, secure password for production environments.

13. Shell into container

```
docker exec -it mariadb-docker bash
```

14. Login to MRDB inside container using the root password specified in step 12.

```
$ mariadb -pyoursecurepassword
```

15. Setup admin account with permission for remote connection, configure access control
    Execute these SQL commands in sequence:

```
MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';
MariaDB [(none)]> GRANT ALL ON _._ to 'admin'@'%' WITH GRANT OPTION;
MariaDB [(none)]> SHOW GRANTS FOR admin;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

16. Setup service account for your app with permission for remote connection, configure access control
    Execute these SQL commands in sequence:

```
MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';
MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON *.* TO 'yourappname'@'%';
MariaDB [(none)]> SHOW GRANTS FOR yourappname;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

17. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

Copy the external IP address of your VM instance from the Console in the VM instances list.

To run your database creation script using MariaDB, open a new terminal window and navigate to the directory containing the script, `init.sql`. Then, execute the following command, replacing `ww.xx.yyy.zzz` with your IP address:

```
$ mariadb --host=your_ip_address --port=3306 --user=admin --password=admin -e "SOURCE init.sql"
```

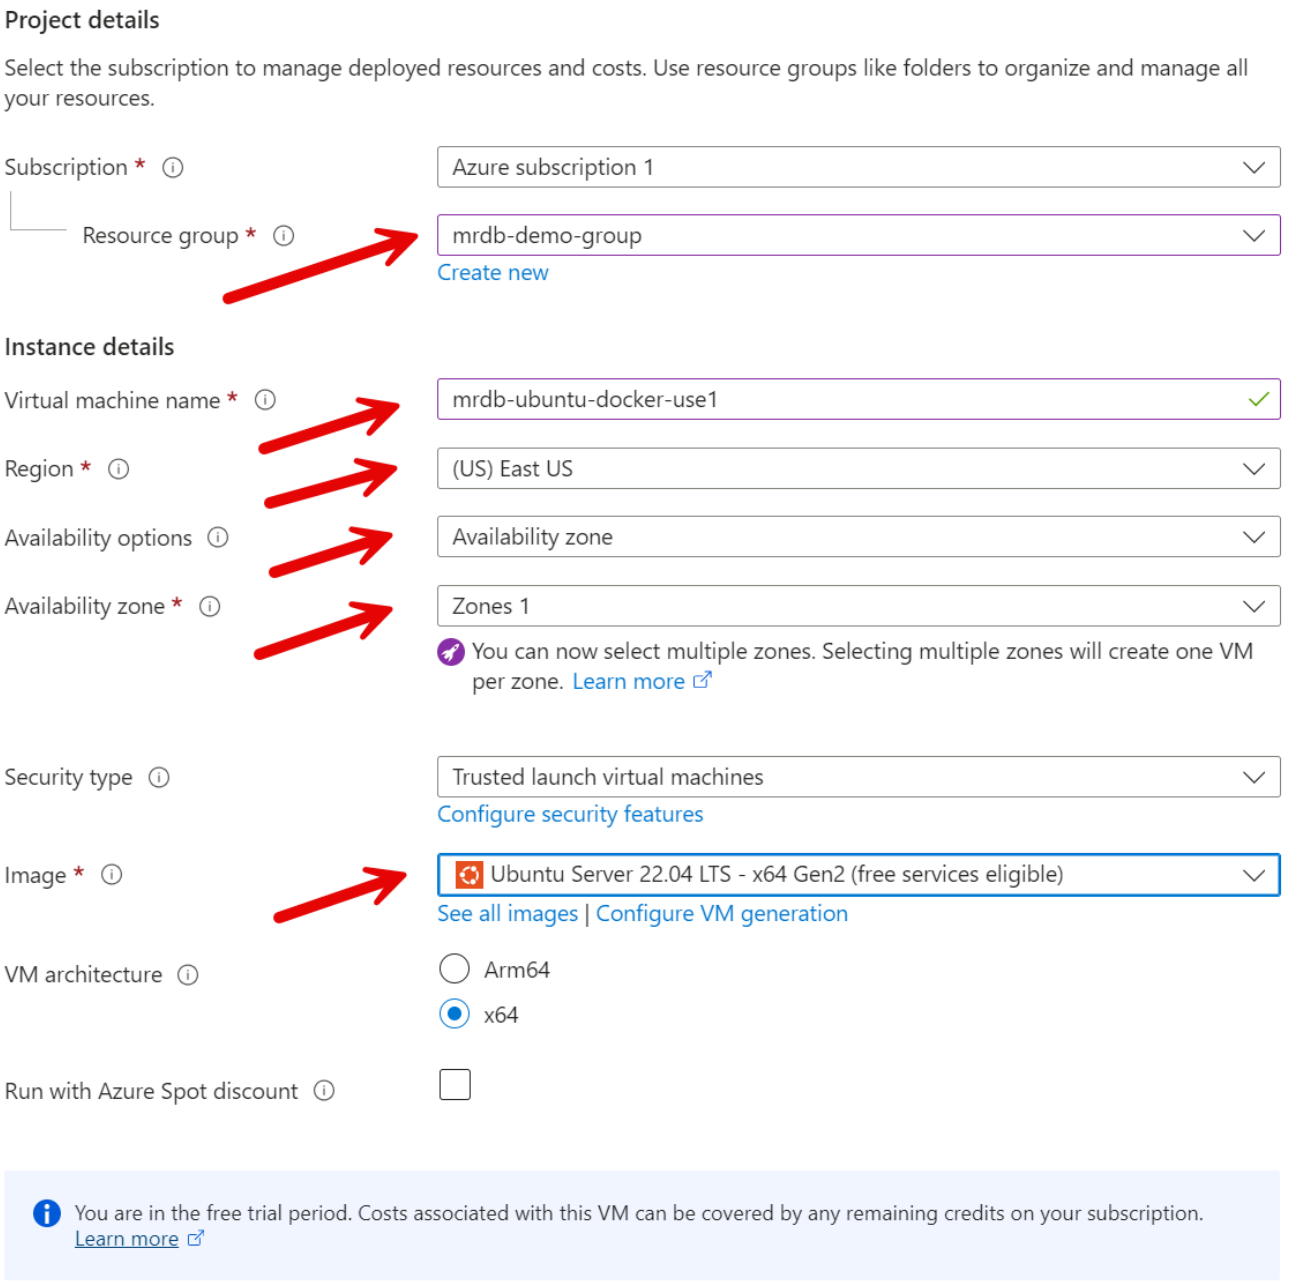
Docker and Microsoft Azure

This process shows how to deploy MariaDB in a Docker container running on an Azure VM instance. First we'll create the Azure VM, then we'll deploy Docker to it. After that, we'll pull the MariaDB Docker image which we'll use to create a running container with a MariaDB instance. Finally, we'll load a sample database into the MariaDB instance.

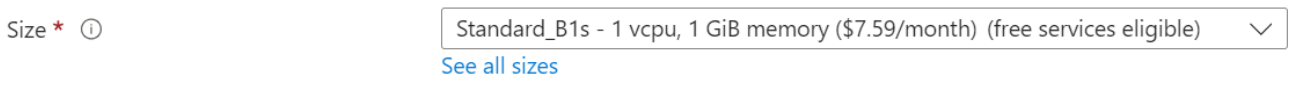
Create a VM in Azure

1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.
2. Login to Azure, navigate to Azure Virtual Machine
3. Create VM. Give the VM a name (e.g. mrdb-ubuntu-docker-use1), and create new or use an existing resource group. Selection region and availability zone, and choose Ubuntu 22.04 LTS x64 (free services eligible).



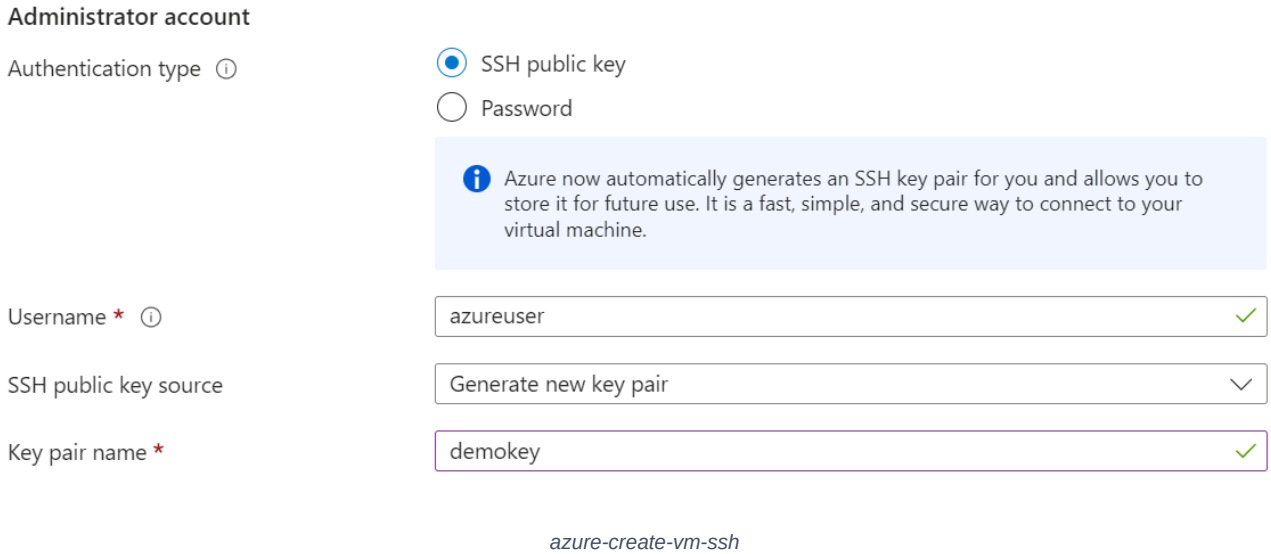
azure-create-vm

4. Choose the VM instance size, like a B1s or similar free tier. Note that Azure free works on a credit based system for new accounts



azure-create-vm-size

5. Configure an administrator account and generate a new key pair, and give the key pair a name.



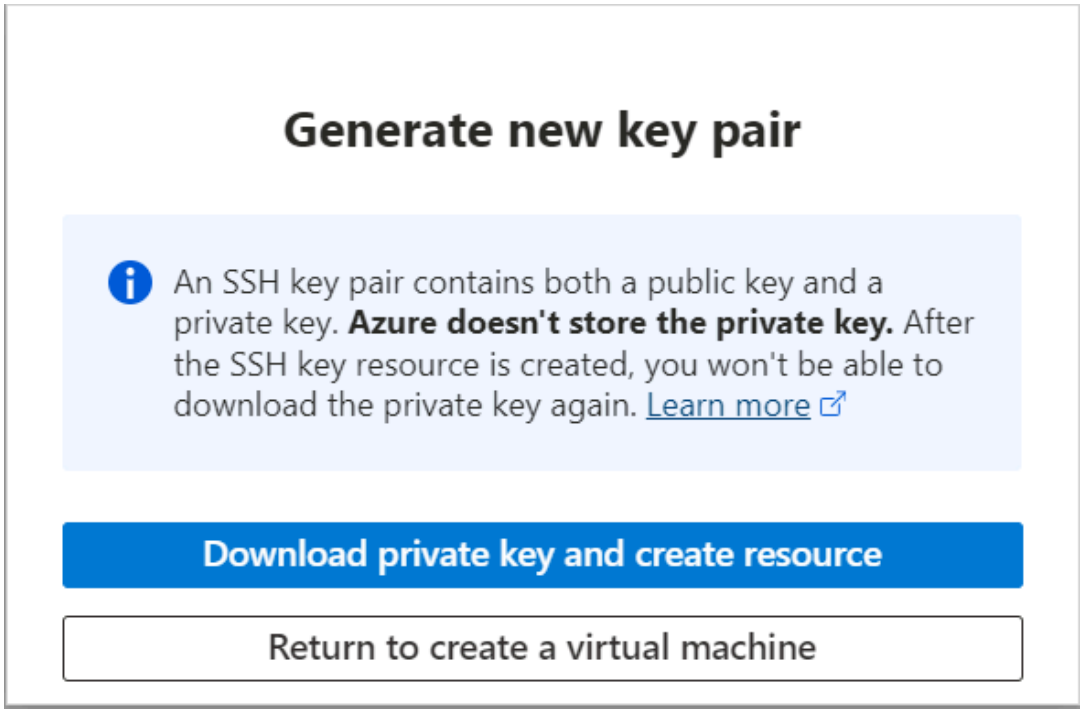
azure-create-vm-ssh

6. Click “Review + Create” at the very bottom of the “create virtual machine” page to create the VM.

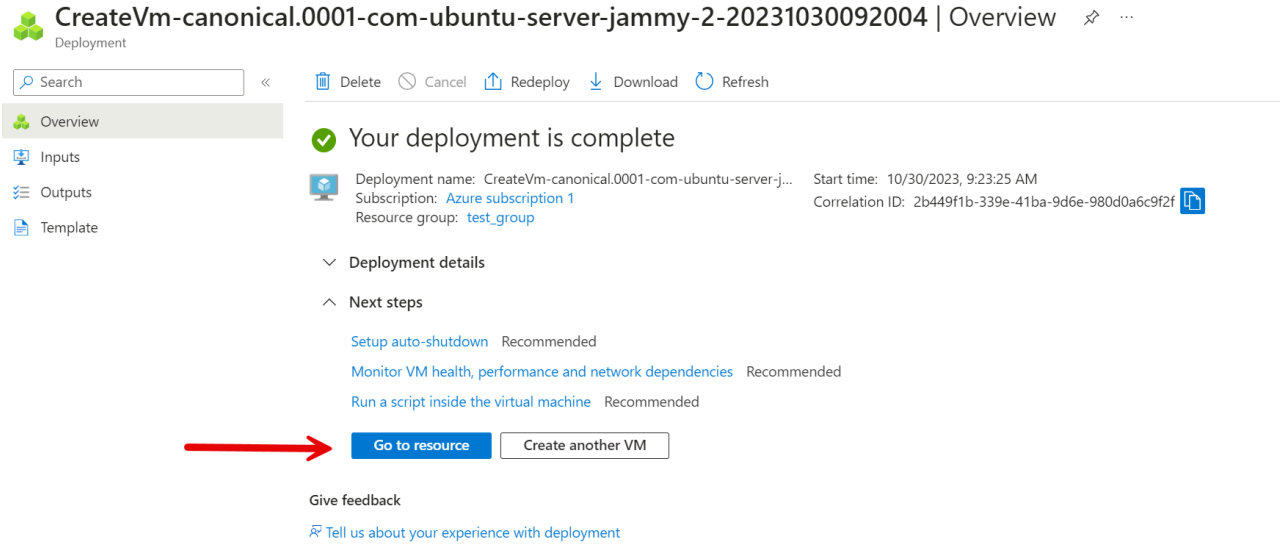
7. Download the SSH keys and them in a safe place, you will need them later. For this example, let’s name the key file `mrdb-docker-pk.pem`.

If your local machine is Linux or you are using WSL on Windows, open a terminal window and:

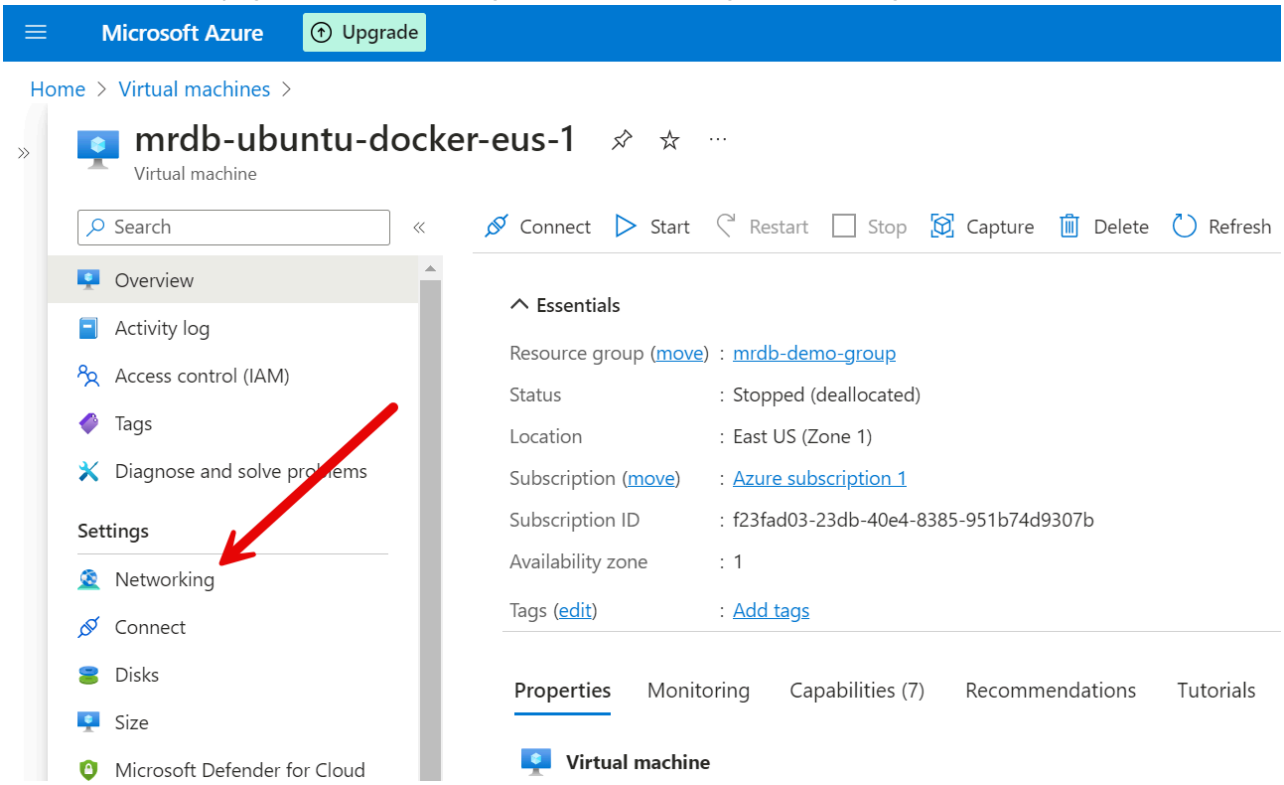
```
mv /mnt/c/ ~/.ssh/
chmod 400 ~/.ssh/
```



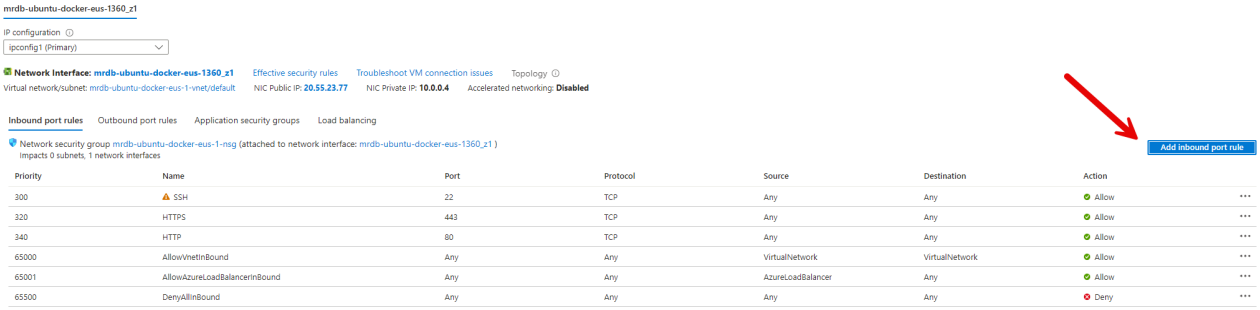
8. Once the VM is deployed, “click to resource” to get back to the virtual machine’s overview page.



9. From the overview page, the left-hand navigation, choose settings > networking.



10. Click “add inbound port rule”



11. Configure the port rule to allow port TCP 3306 inbound (mySQL) so that you can make external connections from your local Maria DB command line client, to the dockerized Maria DB instance in your Azure Linux VM.

AllowCidrBlockCustom3306Inbound

mrdb-ubuntu-docker-eus-1-nsg

Source

- Deny

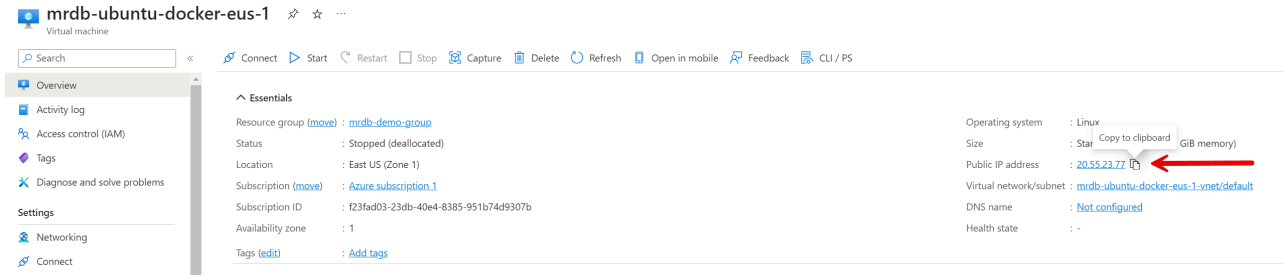
Priority *
350

Name
AllowCidrBlockCustom3306Inbound

Description
MariaDB

Mysql DB port 3306 is exposed to the Internet. We do not recommend exposing database ports to the Internet and suggest only exposing them to your front-end tier inside your virtual network.

12. Navigate back to the virtual machine's overview page. Then copy the public IP address to the clipboard.



Install Docker on the Azure VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

16. To connect to your remote server using SSH, open a terminal window and use the following command, replacing placeholders with your specific details:

```
ssh -i ~/.ssh/your-keyfile.pem azureuser@your.ip.address
```

    - Replace `your-keyfile.pem` with your private key file name.
    - Replace `your.ip.address` with your actual IP address from step 12.

    If you forget your admin details, go to Azure's left-hand navigation, select **Settings** > **Connect**. It will show the public IP address, admin username, and port.

17. Are you sure you want to continue connecting (yes/no/[fingerprint])?
    Say yes

18. To switch to the root user, use the following command:

```
sudo su
```

19.

```
Microsoft Azure offers two machine types with pre-installed Docker. If you need to reinstall Docker or
choose a machine type without Docker pre-installed, you can install it manually. Connect to your machine
via SSH and use the following command:
```

```
```bash
curl -fsSL get.docker.com | sudo sh
```
```

Pull the MariaDB Docker image and create the container

20. To download the latest MariaDB Docker image, run the following command:

```
docker pull mariadb:lts
```

21. To start the MariaDB Docker process, open your terminal or command line and enter the following command:

```
docker run --detach --name mariadb-docker -v C:\Users\YourUID\Documents\YourDirName:/var/lib/mysql:Z -
p 3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts
```

- Use the `-v` flag to mount a directory for persistent storage under `/var/lib/mysql`.
- Windows paths like `C:\Users\YourUID\Documents\YourDirName` should be specified as shown above.
- Ensure paths are absolute, not relative.
- Replace `yoursecurepassword` with a strong password, especially for environments beyond development.

22. To access the MariaDB container's shell, use the following command:

```
```bash
```

```
docker exec -it mariadb-docker bash
```
```

23. To login to MRDB inside the container, use the root password from step 20:

```
```bash
mariadb -p'yoursecurepassword'
```
```

24. Setup admin account with permission for remote connection, configure access control

```
MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';
MariaDB [(none)]> GRANT ALL ON *.* to 'admin'@'%' WITH GRANT OPTION;
MariaDB [(none)]> SHOW GRANTS FOR admin;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

25. Setup service account for your app with permission for remote connection, configure access control

```
MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';
MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON _._ to 'yourappname'@'%';
MariaDB [(none)]> SHOW GRANTS FOR yourappname;
```

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

26. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

Open a new local terminal window and navigate to the directory containing your `init.sql` script. Then, run the command: `mariadb --host=ww.xx.yyy.zzz --port=3306 --user=admin --password=admin -e "SOURCE init.sql"`, replacing `ww.xx.yyy.zzz` with your server's IP address.

Docker Official Image Frequently Asked Questions

Frequently asked questions about the Docker Official Image

How to Reset Passwords

If you have an existing data directory and wish to reset the root and user passwords, and to create a database which the user can fully modify, perform the following steps.

First create a `passwordreset.sql` file:

```
CREATE USER IF NOT EXISTS root@localhost IDENTIFIED BY 'thisismyrootpassword';
SET PASSWORD FOR root@localhost = PASSWORD('thisismyrootpassword');
GRANT ALL ON *.* TO root@localhost WITH GRANT OPTION;
GRANT PROXY ON ''@'%' ON root@localhost WITH GRANT OPTION;
CREATE USER IF NOT EXISTS root@'%' IDENTIFIED BY 'thisismyrootpassword';
SET PASSWORD FOR root@'%' = PASSWORD('thisismyrootpassword');
GRANT ALL ON *.* TO root@'%' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' ON root@'%' WITH GRANT OPTION;
CREATE USER IF NOT EXISTS myuser@'%' IDENTIFIED BY 'thisismyuserpassword';
SET PASSWORD FOR myuser@'%' = PASSWORD('thisismyuserpassword');
CREATE DATABASE IF NOT EXISTS databasename;
GRANT ALL ON databasename.* TO myuser@'%';
```

Adjust `myuser`, `databasename` and passwords as needed.

Then:

```
$ docker run --rm -v /my/own/datadir:/var/lib/mysql -v /my/own/passwordreset.sql:/passwordreset.sql:z
%%IMAGE%%:latest --init-file=/passwordreset.sql
```

On restarting the MariaDB container in this `/my/own/datadir`, the `root` and `myuser` passwords will be reset.

Temp Server Start Timeout

Question, are you getting errors like the following where a temporary server start fails to succeed in 30 seconds?

Example of log:

```
2023-01-28 12:53:42+00:00 [Note] [Entrypoint]: Starting temporary server
2023-01-28 12:53:42+00:00 [Note] [Entrypoint]: Waiting for server startup
2023-01-28 12:53:42 0 [Note] mariadbd (server 10.10.2-MariaDB-1:10.10.2+maria~ubu2204) starting as
process 72 ...
....
2023-01-28 12:53:42 0 [Note] InnoDB: Setting file './ibtmp1' size to 12.000MiB. Physically writing the
file full; Please wait ...
2023-01-28 12:54:13 0 [Note] mariadbd: ready for connections.
Version: '10.10.2-MariaDB-1:10.10.2+maria~ubu2204'  socket: '/run/mysqld/mysqld.sock'  port: 0
mariadb.org binary distribution
2023-01-28 12:54:13+00:00 [ERROR] [Entrypoint]: Unable to start server.
```

The timeout on a temporary server start is a quite generous 30 seconds.

The lack of a message like the following indicates it failed to complete writing a temporary file of 12MiB in 30 seconds.

```
2023-01-28 12:53:46 0 [Note] InnoDB: File './ibtmp1' size is now 12.000MiB.
```

If the datadir where this is stored is remote storage maybe it's a bit slow. It's ideal to have an InnoDB temporary path local so this can be configured using the command or configuration setting:

```
innodb_temp_data_file_path=/dev/shm/ibtmp1:12M:autoextend
```

Note: depending on container runtime this space may be limited.

Creating a replication pair

`MARIADB_REPLICATION_USER` / `MARIADB_REPLICATION_PASSWORD` specify the authentication for the connection. The `MARIADB_MASTER_HOST` is the indicator that it is a replica and specifies the container aka hostname, of the master.

A `docker-compose.yml` example:

```
version: "3"
services:
  master:
    image: mariadb:latest
    command: --log-bin --log-basename=mariadb
    environment:
      - MARIADB_ROOT_PASSWORD=password
      - MARIADB_USER=testuser
      - MARIADB_PASSWORD=password
      - MARIADB_DATABASE=testdb
      - MARIADB_REPLICATION_USER=repl
      - MARIADB_REPLICATION_PASSWORD=replicationpass
    healthcheck:
      test: ["CMD", "healthcheck.sh", "--connect", "--innodb_initialized"]
      interval: 10s
      timeout: 5s
      retries: 3
  replica:
    image: mariadb:latest
    command: --server-id=2 --log-basename=mariadb
    environment:
      - MARIADB_ROOT_PASSWORD=password
      - MARIADB_MASTER_HOST=master
      - MARIADB_REPLICATION_USER=repl
      - MARIADB_REPLICATION_PASSWORD=replicationpass
      - MARIADB_HEALTHCHECK_GRANTS=REPLICA MONITOR
    healthcheck:
      test: ["CMD", "healthcheck.sh", "--connect", "--replication_io", "--replication_sql", "--
replication_seconds_behind_master=1", "--replication"]
      interval: 10s
      timeout: 5s
      retries: 3
    depends_on:
      master:
        condition: service_healthy
```

Event Scheduler: An error occurred when initializing system tables. Disabling the Event Scheduler.

This will show up in the container log as:

```
2024-01-29 17:38:13 0 [ERROR] Incorrect definition of table mysql.event: expected column 'definer' at
position 3 to have type varchar(, found type char(141).
2024-01-29 17:38:13 0 [ERROR] mariadbd: Event Scheduler: An error occurred when initializing system
tables. Disabling the Event Scheduler.
```

The cause is the underlying table has change structure from the last MariaDB version. The easiest solution to this is to start the container with the environment variable MARIADB_AUTO_UPGRADE=1 and system tables will be updated. This is safe to keep on as it detects the version installed. The next start should not show this error.

InnoDB: Upgrade after a crash is not supported. The redo log was created with MariaDB X.Y.Z

This will show up in the error log as:

```
2022-05-23 12:29:20 0 [ERROR] InnoDB: Upgrade after a crash is not supported. The redo log was created
with MariaDB 10.5.4.
2022-05-23 12:29:20 0 [ERROR] InnoDB: Plugin initialization aborted with error Generic error
```

This is attempting to start on a higher MariaDB version when the shutdown of the previous version crashed.

By crashed, it means the MariaDB was force killed or had a hard power failure. MariaDB, being a durable database, can recover from these, if started with the same version. The redo log however is a less stable format, so the recovery has to be on the same Major.Minor version, in this case 10.5. This error message is saying that you when from force killed MariaDB to a later version.

So whenever you encounter this message. Start with the again with the tag set to the version in the error message, like 10.5.4, or as the redo long format is consistent in the Major.Minor version 10.5 is sufficient. After this has been started correctly, cleanly shut the service down and it will be recovered.

The logs on shutdown should have a message like:

```
2023-11-06 10:49:23 0 [Note] InnoDB: Shutdown completed; log sequence number 84360; transaction id 49
2023-11-06 10:49:23 0 [Note] mariadbd: Shutdown complete
```

After you see this, you can update your MariaDB tag to a later version.

Every MariaDB start gives permission denied messages

```
2024-02-06 03:03:18+00:00 [Note] [Entrypoint]: Entrypoint script for MariaDB Server
1:10.11.6+maria~ubu2204 started.
/usr/local/bin/docker-entrypoint.sh: line 600: /var/lib/mysql//mysql_upgrade_info: Permission denied
2024-02-06 03:03:18+00:00 [Note] [Entrypoint]: MariaDB upgrade (mariadb-upgrade) required, but skipped
due to $MARIADB_AUTO_UPGRADE setting
2024-02-06  3:03:18 0 [Warning] Can't create test file '/var/lib/mysql/80a2bb81d698.lower-test' (Errcode:
13 "Permission denied")
2024-02-06  3:03:18 0 [Note] Starting MariaDB 10.11.6-MariaDB-1:10.11.6+maria~ubu2204 source revision
fecd78b83785d5ae96f2c6ff340375be803cd299 as process 1
2024-02-06  3:03:18 0 [ERROR] mariadbd: Can't create/write to file './ddl_recovery.log' (Errcode: 13
"Permission denied")
2024-02-06  3:03:18 0 [ERROR] DDL_LOG: Failed to create ddl log file: ./ddl_recovery.log
2024-02-06  3:03:18 0 [ERROR] Aborting
```

Or:

```
2024-08-16  4:54:05 0 [ERROR] InnoDB: Operating system error number 13 in a file operation.
2024-08-16  4:54:05 0 [ERROR] InnoDB: The error means mariadbd does not have the access rights to the
directory.
```

In this case, the container is running as a user that, inside the container, does not have write permissions on the datadir `/varlib/mysql`.

Bad magic header in tc log

From the transaction coordinator log this is a corrupted file. This will have a log message like the following:

```
2024-05-21  8:55:58 0 [Note] Recovering after a crash using tc.log
2024-05-21  8:55:58 0 [ERROR] Bad magic header in tc log
2024-05-21  8:55:58 0 [ERROR] Crash recovery failed. Either correct the problem (if it's, for example,
out of memory error) and restart, or delete tc log and start server with --tc-heuristic-recover=
{commit|rollback}
2024-05-21  8:55:58 0 [ERROR] Can't init tc log
2024-05-21  8:55:58 0 [ERROR] Aborting
```

The cause of this is headed by the first not, its a crash recovery. Like the Every MariaDB start is a crash recovery answer below, this is an indication that MariaDB wasn't given enough time by the container runtime to shutdown cleanly. While MariaDB was shutdown, the new version that was started is a newer MariaDB and doesn't recognise the updated magic information in the header.

MariaDB should always perform crash recovery with the same version that actually crashed, the same major/minor number at least.

As such the solution is to restart the container with the previous MariaDB version that was running, and configure the container runtime to allow a longer stop time. See the Every MariaDB start is a crash recovery answer below to see if the timeout is sufficiently extended.

Every MariaDB start is a crash recovery

Do you get on every start:

```
db-1  | 2023-02-25 19:10:02 0 [Note] Starting MariaDB 10.11.2-MariaDB-1:10.11.2+maria~ubu2204-log source
revision cafba8761af55ae16cc69c9b53a341340a845b36 as process 1
db-1  | 2023-02-25 19:10:02 0 [Note] mariadbd: Aria engine: starting recovery
db-1  | tables to flush: 3 2 1 0
db-1  |  (0.0 seconds);
db-1  | 2023-02-25 19:10:02 0 [Note] mariadbd: Aria engine: recovery done
...
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Initializing buffer pool, total size = 32.000GiB, chunk size
= 512.000MiB
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Completed initialization of buffer pool
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: File system buffers for log disabled (block size=512 bytes)
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Starting crash recovery from checkpoint LSN=193796878816
```

Container runtimes are assume to start and stop very quickly. Check the shutdown logs. They may be a log like:

```
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Starting shutdown...
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Dumping buffer pool(s) to /var/lib/mysql/ib_buffer_pool
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Restricted to 519200 pages due to
innodb_buf_pool_dump_pct=25
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Buffer pool(s) dump completed at 230226 13:03:17
db-1 exited with code 0
```

Note that the logs didn't include the following messages:

```
db-1  | 2023-02-26 13:03:43 0 [Note] InnoDB: Shutdown completed; log sequence number 46590; transaction
id 15
db-1  | 2023-02-26 13:03:43 0 [Note] mariadbd: Shutdown complete
```

As these messages aren't here, the container was killed off before it could just down cleanly. When this happens, the startup will be a crash recovery and you won't be able to upgrade your MariaDB instance (previous FAQ) to the next Major.Minor version.

Solution is to extend the timeout in the container runtime to allow MariaDB to complete its shutdown.

How do I create a `mariaDB-backup` of the data?

```
docker volume create backup
docker run --name mdb -v backup:/backup -v datavolume:/var/lib/mysql mariadb
docker exec mdb mariadb-backup --backup --target-dir=/backup/d --user root --password soverysecret
docker exec mdb mariadb-backup --prepare --target-dir=/backup/d
docker exec mdb sh -c '[ ! -f /backup/d/.my-healthcheck.cnf ] && cp /var/lib/mysql/.my-healthcheck.cnf
/backup/d'
docker exec --workdir /backup/d mdb tar -Jcf ../backup.tar.xz .
docker exec mdb  rm -rf /backup/d
```

How do I restore from a MariaDB-backup

With the backup prepared like previously:

```
docker run -v backup:/docker-entrypoint-initdb.d -v newdatavolume:/var/lib/mysql mariadb
```

How to start MariaDB with Apptainer

Because Apptainer has all the filesystems readonly except or the volume, the /run/mysqld directory is used as a pidfile and socket directory. An easy way is to mark this as a scratch directory.

```
mkdir mydatadir
apptainer run --no-home --bind $PWD/mydatadir:/var/lib/mysql --env MARIADB_RANDOM_ROOT_PASSWORD=1 --net -
-network-args "portmap=3308:3306/tcp" --fakeroot --scratch=/run/mysqld  docker://mariadb:10.5
```

Alternately:

```
apptainer run --no-home --bind $PWD/mydatadir:/var/lib/mysql --env MARIADB_RANDOM_ROOT_PASSWORD=1 --net -
-network-args "portmap=3308:3306/tcp" --fakeroot   docker://mariadb:10.5 --
socket=/var/lib/mysql/mariadb.sock --pid-file=/var/lib/mysql/mariadb.pid
```

Why does the MariaDB container start as root?

The MariaDB entrypoint briefly starts as `root`, and if an explicit volume is there, the owner of this volume will be `root`. To allow MariaDB to use the `CHOWN` capability to change the volume owner to a user that can write to this volume, it needs to be briefly `root`. After this one action is taken, the entrypoint uses `gosu` to drop to a non-root user and continues execution. There is no accessible exploit vector to remotely affect the container startup when it is briefly running as the `root` user.

Can I run the MariaDB container as an arbitrary user?

In a Docker Compose file or when running a command, you can specify the user with `user: 2022` or `--user 2022` to execute the entrypoint as user ID 2022. Ensure the datadir volume has appropriate permissions for MariaDB access, aligning with local ownership by user ID 2022. Note that inside the container, user names are not defined as they are outside, so using numeric IDs offers better portability.

This page is licensed: CC BY-SA / Gnu FDL

Installing and Using MariaDB via Docker

Sometimes we want to install a specific version of MariaDB, MariaDB ColumnStore, or MaxScale on a certain system, but no packages are available. Or maybe, we simply want to isolate MariaDB from the rest of the system, to be sure that we won't cause any damage.

A virtual machine would certainly serve the scope. However, this means installing a system on the top of another system. It requires a lot of resources.

In many cases, the best solution is using containers. Docker is a framework that runs containers. A container is meant to run a specific daemon, and the software that is needed for that daemon to properly work. Docker does not virtualize a whole system; a container only includes the packages that are not included in the underlying system.

Docker requires a very small amount of resources. It can run on a virtualized system. It is used both in development and in production environments. Docker is an open source project, released under the Apache License, version 2.

Note that, while your package repositories could have a package called `docker`, it is probably not the Docker we are talking about. The Docker package could be called `docker.io` or `docker-engine`.

For information about installing Docker, see Get Docker in Docker documentation.

Installing Docker on Your System with the Universal Installation Script

The script below will install the Docker repositories, required kernel modules and packages on the most common Linux distributions:

```
curl -sSL https://get.docker.com/ | sh
```

Starting dockerd

On some systems you may have to start the `dockerd daemon` yourself:

```
sudo systemctl start docker
sudo gpasswd -a "${USER}" docker
```

If `dockerd` is not running, you will encounter the following error when using most `docker` commands:

```
Cannot connect to the Docker daemon at unix:///var/run/docker.sock. Is the docker daemon running?
```

Using MariaDB Images

The easiest way to use MariaDB on Docker is choosing a MariaDB image and creating a container.

Downloading an Image

You can download a MariaDB image for Docker from the Official Docker MariaDB, or choose another image that better suits your needs. You can search Docker Hub (the official set of repositories) for an image with this command:

```
docker search mariadb
```

Once you have found an image that you want to use, you can download it via Docker. Some layers including necessary dependencies will be downloaded too. Note that, once a layer is downloaded for a certain image, Docker will not need to download it again for another image.

For example, if you want to install the default MariaDB image, you can type:

```
docker pull mariadb:10.6
```

This will install the 10.6 version.

You will see a list of necessary layers. For each layer, Docker will say if it is already present, or its download progress.

To get a list of installed images:

```
docker images
```

Creating a Container

An image is not a running process; it is just the software needed to be launched. To run it, we must create a container first. The command needed to create a container can usually be found in the image documentation. For example, to create a container for the official MariaDB image:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d
docker.io/library/mariadb:10.3
```

`mariadbtest` is the name we want to assign the container. If we don't specify a name, an id will be automatically generated.

10.2 and 10.5 are also valid target versions:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d
docker.io/library/mariadb:10.2
```

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306  -d
docker.io/library/mariadb:10.5
```

Optionally, after the image name, we can specify some options for mariadbd. For example:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d mariadb:10.3 --log-bin --
binlog-format=MIXED
```

Docker will respond with the container's id. But, just to be sure that the container has been created and is running, we can get a list of running containers in this way:

```
docker ps
```

We should get an output similar to this one:

```
CONTAINER ID        IMAGE                     COMMAND                CREATED             STATUS
PORTS               NAMES
819b786a8b48        mariadb                   "/docker-entrypoint.   4 minutes ago       Up 4 minutes
3306/tcp            mariadbtest
```

Running and Stopping the Container

Docker allows us to restart a container with a single command:

```
docker restart mariadbtest
```

The container can also be stopped like this:

```
docker stop mariadbtest
```

The container will not be destroyed by this command. The data will still live inside the container, even if MariaDB is not running. To restart the container and see our data, we can issue:

```
docker start mariadbtest
```

With `docker stop`, the container will be gracefully terminated: a `SIGTERM` signal will be sent to the `mariadbd` process, and Docker will wait for the process to shutdown before returning the control to the shell. However, it is also possible to set a timeout, after which the process will be immediately killed with a `SIGKILL`. Or it is possible to immediately kill the process, with no timeout.

```
docker stop --time=30 mariadbtest
docker kill mariadbtest
```

In case we want to destroy a container, perhaps because the image does not suit our needs, we can stop it and then run:

```
docker rm mariadbtest
```

Note that the command above does not destroy the data volume that Docker has created for /var/lib/mysql. If you want to destroy the volume as well, use:

```
docker rm -v mariadbtest
```

Automatic Restart

When we start a container, we can use the `--restart` option to set an automatic restart policy. This is useful in production.

Allowed values are:

- `no`: No automatic restart.
- `on-failure`: The container restarts if it exits with a non-zero exit code.
- `unless-stopped`: Always restart the container, unless it was explicitly stopped as shown above.
- `always`: Similar to `unless-stopped`, but when Docker itself restarts, even containers that were explicitly stopped will restart.

It is possible to change the restart policy of existing, possibly running containers:

```
docker update --restart always mariadb
# or, to change the restart policy of all containers:
docker update --restart always $(docker ps -q)
```

A use case for changing the restart policy of existing containers is performing maintenance in production. For example, before upgrading the Docker version, we may want to change all containers restart policy to `always`, so they will restart as soon as the new version is up and running. However, if some containers are stopped and not needed at the moment, we can change their restart policy to `unless-stopped`.

Pausing Containers

A container can also be frozen with the `pause` command. Docker will freeze the process using croups. MariaDB will not know that it is being frozen and, when we `unpause` it, MariaDB will resume its work as expected.

Both `pause` and `unpause` accept one or more container names. So, if we are running a cluster, we can freeze and resume all nodes simultaneously:

```
docker pause node1 node2 node3
docker unpause node1 node2 node3
```

Pausing a container is very useful when we need to temporarily free our system's resources. If the container is not crucial at this moment (for example, it is performing some batch work), we can free it to allow other programs to run faster.

Troubleshooting a Container

If the container doesn't start, or is not working properly, we can investigate with the following command:

```
docker logs mariadbtest
```

This command shows what the daemon sent to the stdout since the last attempt of starting - the text that we typically see when we invoke `mariadbd` from the command line.

On some systems, commands such as `docker stop mariadbtest` and `docker restart mariadbtest` may fail with a permissions error. This can be caused by AppArmor, and even `sudo` won't allow you to execute the command. In this case, you will need to find out which profile is causing the problem and correct it, or disable it. **Disabling AppArmor altogether is not recommended, especially in production.**

To check which operations were prevented by AppArmor, see AppArmor Failures in AppArmor documentation.

To disable a profile, create a symlink with the profile name (in this example, `mariadbd`) to `etc/apparmor.d/disable`, and then reload profiles:

```
ln -s /etc/apparmor.d/usr.sbin.mariadbd /etc/apparmor.d/disable/
sudo apparmor_parser -R /etc/apparmor.d/usr.sbin.mariadbd
```

For more information, see Policy Layout in AppArmor documentation.

After disabling the profile, you may need to run:

```
sudo service docker restart
docker system prune --all --volumes
```

Restarting the system will then allow Docker to operate normally.

Accessing the Container

To access the container via Bash, we can run this command:

```
docker exec -it mariadbtest bash
```

Now we can use normal Linux commands like *cd*, *ls*, etc. We will have root privileges. We can even install our favorite file editor, for example:

```
apt-get update
apt-get install vim
```

In some images, no repository is configured by default, so we may need to add them.

Note that if we run mariadb-admin shutdown or the SHUTDOWN command to stop the container, the container will be deactivated, and we will automatically exit to our system.

Connecting to MariaDB from Outside the Container

If we try to connect to the MariaDB server on `localhost`, the client will bypass networking and attempt to connect to the server using a socket file in the local filesystem. However, this doesn't work when MariaDB is running inside a container because the server's filesystem is isolated from the host. The client can't access the socket file which is inside the container, so it fails to connect.

Therefore connections to the MariaDB server must be made using TCP, even when the client is running on the same machine as the server container.

Find the IP address that has been assigned to the container:

```
docker inspect -f '{{range .NetworkSettings.Networks}}{{.IPAddress}}{{end}}' mariadbtest
```

You can now connect to the MariaDB server using a TCP connection to that IP address.

Forcing a TCP Connection

After enabling network connections in MariaDB as described above, we will be able to connect to the server from outside the container.

On the host, run the client and set the server address ("-h") to the container's IP address that you found in the previous step:

```
mysql -h 172.17.0.2 -u root -p
```

This simple form of the connection should work in most situations. Depending on your configuration, it may also be necessary to specify the port for the server or to force TCP mode:

```
mysql -h 172.17.0.2 -P 3306 --protocol=TCP -u root -p
```

Port Configuration for Clustered Containers and Replication

Multiple MariaDB servers running in separate Docker containers can connect to each other using TCP. This is useful for forming a Galera cluster or for replication.

When running a cluster or a replication setup via Docker, we will want the containers to use different ports. The fastest way to achieve this is mapping the containers ports to different port on our system. We can do this when creating the containers (`docker run` command), by using the `-p` option, several times if necessary. For example, for Galera nodes we will use a mapping similar to this one:

```
-p 4306:3306 -p 5567:5567 -p 5444:5444 -p 5568:5568
```

Installing MariaDB on Another Image

It is possible to download a Linux distribution image, and to install MariaDB on it. This is not much harder than installing MariaDB on a regular operating system (which is easy), but it is still the hardest option. Normally we will try existing images first. However, it is possible that no image is available for the exact version we want, or we want a custom installation, or perhaps we want to use a distribution for which no images are available. In these cases, we will install MariaDB in an operating system image.

Daemonizing the Operating System

First, we need the system image to run as a daemon. If we skip this step, MariaDB and all databases will be lost when the container stops.

To demonize an image, we need to give it a command that never ends. In the following example, we will create a Debian Jessie daemon that constantly pings the 8.8.8.8 special address:

```
docker run --name debian -p 3306:3306 -d debian /bin/sh -c "while true; do ping 8.8.8.8; done"
```

Installing MariaDB

At this point, we can enter the shell and issue commands. First we will need to update the repositories, or no packages will be available. We can also update the packages, in case some of them are newer than the image. Then, we will need to install a text editor; we will need it to edit configuration files. For example:

```
# start an interactive Bash session in the container
docker exec -ti debian bash
apt-get -y update
apt-get -y upgrade
apt-get -y install vim
```

Now we are ready to install MariaDB in the way we prefer.

MariaDB Container Cheat Sheet

Get the images

Images can be found on MariaDB Docker Hub. To get the list of images, run this command:

```
$ docker images -a
```

Create the network

```
$ docker network create mynetwork
```

It is good practice to create the container network and attach the container to the network.

Start The Container With Server Options

To start the container in the background with the MariaDB server image, run:

```
$ docker run --rm --detach \
  --env MARIADB_ROOT_PASSWORD=sosecret \
  --network mynetwork \
  --name mariadb-server \
  mariadb:latest
```

Additionally, environment variables are also provided.

Get the list of running containers

```
$ docker ps
CONTAINER ID   IMAGE            COMMAND                  CREATED          STATUS          PORTS
NAMES
ad374ec8a272   mariadb:latest   "docker-entrypoint.s…"   3 seconds ago    Up 1 second     3306/tcp
mariadb-server
```

Note: Specify the flag `-a` in case you want to see all containers

Start the client from the container

To start the *mariadb* client inside the created container and run specific commands, run the following:

```
$ docker exec -it mariadb-server mariadb -psosecret -e "SHOW PLUGINS"
```

Inspect logs of a container

```
$ docker logs mariadb-server
```

In the logs you can find status information about the server, plugins, generated passwords, errors and so on.

Restart the container

```
$ docker restart mariadb-server
```

Run commands within the container

```
$ docker exec -it mariadb-server bash
```

Use a volume to specify configuration options

```
$ docker run --detach --env MARIADB_USER=anel \
  --env MARIADB_PASSWORD=anel \
  --env MARIADB_DATABASE=my_db \
  --env MARIADB_RANDOM_ROOT_PASSWORD=1 \
  --volume $PWD/my_container_config:/etc/mysql/conf.d:z \
  --network mynetwork \
  --name mariadb-server1 \
   mariadb:latest
```

One can specify custom configuration files through the `/etc/mysql/conf.d` volume during container startup.

Use a volume to specify grants during container start

```
$ docker run --detach --env MARIADB_USER=anel\
  --env MARIADB_PASSWORD=anel \
  --env MARIADB_DATABASE=my_db \
  --env MARIADB_RANDOM_ROOT_PASSWORD=1 \
  --volume $PWD/my_init_db:/docker-entrypoint-initdb.d \
  --network mynetwork \
  --name mariadb-server1 \
   mariadb:latest
```

User created with the environment variables has full grants only to the `MARIADB_DATABASE`. In order to override those grants, one can specify grants to a user, or execute any SQL statements from host file to **docker-entrypoint-initdb.d**. In the `local_init_dir` directory we can find the file, created like this:

```
$ echo "GRANT ALL PRIVILEGES ON *.* TO anel;" > my_init_db/my_grants.sql
```

MariaDB Enterprise Server Docker Official Image Environment Variables

When you start the image, you can adjust the initialization of the MariaDB Server instance by passing one or more environment variables on the docker run command line. Do note that all of the variables below, except `MARIADB_AUTO_UPGRADE`, will have no effect if you start the container with a data directory that already contains a database: any pre-existing database will always be left untouched on container startup.

All tags from `10.6` and above, `MARIADB_*` variables will be used in preference to `MYSQL_*` variables.

One of the following is required: `MARIADB_ROOT_PASSWORD_HASH`, `MARIADB_ROOT_PASSWORD`, `MARIADB_ALLOW_EMPTY_ROOT_PASSWORD`, or `MARIADB_RANDOM_ROOT_PASSWORD` (including `*_FILE` equivalents).

Other environment variables are optional.

Environment Variables

`MARIADB_ROOT_PASSWORD_HASH / MARIADB_ROOT_PASSWORD / MYSQL_ROOT_PASSWORD`

This specifies the password that will be set for the MariaDB root superuser account.

`MARIADB_ALLOW_EMPTY_ROOT_PASSWORD / MYSQL_ALLOW_EMPTY_PASSWORD`

Set to a non-empty value, like `1`, to allow the container to be started with a blank password for the root user.

> **Warning:**
>
> Setting this variable to yes is not recommended unless you really know what you are doing, since this will leave your MariaDB instance completely unprotected, allowing anyone to gain complete superuser access.

`MARIADB_RANDOM_ROOT_PASSWORD / MYSQL_RANDOM_ROOT_PASSWORD`

Define a non-empty value, such as “yes,” to auto-generate a random initial password for the root user. The password will be output to stdout, prefixed with “GENERATED ROOT PASSWORD: …”.

`MARIADB_ROOT_HOST / MYSQL_ROOT_HOST`

`%` is the default hostname part of the root user in MariaDB. This can be changed to any valid hostname. Setting it to `localhost` restricts root access to only the local machine via the Unix socket.

`MARIADB_USER_HOST`

`%` is the default hostname part of the user created through `MYSQL_USER / MARIADB_USER` in MariaDB. This can be changed to any valid hostname or IP. Setting it to `localhost` restricts user access to only the local machine via the Unix socket.

`MARIADB_DATABASE / MYSQL_DATABASE`

This variable allows you to specify the name of a database to be created on image startup.

`MARIADB_USER / MYSQL_USER, MARIADB_PASSWORD_HASH / MARIADB_PASSWORD / MYSQL_PASSWORD`

To create a new user with full access permissions in MariaDB, both `user` and `password` variables are required, along with a designated `database`. This new user will be granted comprehensive privileges (`GRANT ALL`) to the specified `MARIADB_DATABASE`. Note that this method should not be utilized for creating the root superuser, as this user is automatically created with the password provided by the `MARIADB_ROOT_PASSWORD` or `MYSQL_ROOT_PASSWORD` variable.

`MARIADB_MYSQL_LOCALHOST_USER / MARIADB_MYSQL_LOCALHOST_GRANTS`

Set `MARIADB_MYSQL_LOCALHOST_USER` to a non-empty value to create the `mysql@localhost` database user. This user is useful for health checks and backup scripts. The `mysql@localhost` user gets `USAGE` privileges by default. If more access is needed, additional global privileges can be provided as a comma-separated list. Be cautious when sharing a volume containing MariaDB's unix socket (`/var/run/mysqld` by default) as privileges beyond `USAGE` may pose security risks. This user can also be used with `mariadb-backup`. Refer to `healthcheck.sh` for required privileges for each health check test.

`MARIADB_HEALTHCHECK_GRANTS`

Set `MARIADB_HEALTHCHECK_GRANTS` to the grants required to be given to the `healthcheck@localhost`, `healthcheck@127.0.0.1`, `healthcheck@::1`, users. When not specified the default grant is USAGE.

The main value used here will be `[REPLICA MONITOR](#pg-rence-sql-statements-account-management-sql-statements-grant-7cefc036)` for the `[healthcheck --replication](#pg-t-and-administration-docker-and-mariadb-using-healthcheck-sh-db0da349)` test.

`MARIADB_INITDB_SKIP_TZINFO / MYSQL_INITDB_SKIP_TZINFO`

By default, the entrypoint script automatically loads the timezone data needed for the `CONVERT_TZ()` function. If it is not needed, any non-empty value disables timezone loading.

`MARIADB_AUTO_UPGRADE / MARIADB_DISABLE_UPGRADE_BACKUP`

Set `MARIADB_AUTO_UPGRADE` to a non-empty value to have the entrypoint check whether mariadb-upgrade needs to run, and if so, run the upgrade before starting the MariaDB server.

Before the upgrade, a backup of the system database is created in the top of the datadir with the name `system_mysql_backup_*.sql.zst`. This backup process can be disabled by setting `MARIADB_DISABLE_UPGRADE_BACKUP` to a non-empty value.

If `MARIADB_AUTO_UPGRADE` is set, and the `.my-healthcheck.cnf` file is missing, the `healthcheck` users are recreated if they don't exist, `MARIADB_HEALTHCHECK_GRANTS` grants are given, the passwords of the `healthcheck`

users are reset to a random value and the `.my-healthcheck.cnf` file is recreated with the new password populated.

`MARIADB_MASTER_HOST`

When specified, the container will connect to this host and replicate from it.

`MARIADB_REPLICATION_USER / MARIADB_REPLICATION_PASSWORD_HASH / MARIADB_REPLICATION_PASSWORD`

When `MARIADB_MASTER_HOST` is defined, `MARIADB_REPLICATION_USER` and `MARIADB_REPLICATION_PASSWORD` will be used to connect to the master. When not specified, the `MARIADB_REPLICATION_USER` will be created with the `REPLICATION REPLICA` grants needed for a client to initiate replication.

Timezone Configuration

By default, the container operates in the Coordinated Universal Time (UTC) timezone. To configure a specific timezone for the container's operating system and internal processes, utilize the `TZ` environment variable.

Supported Values

The `TZ` variable accepts standard tz database (IANA) timezone identifiers. Examples include `America/New_York`, `Europe/London`, or `Asia/Tokyo`.

Usage Examples

Using `docker run`

You can specify the timezone when starting the container via the command line interface using the `-e` flag:

```
docker run -d \
  --name database-container \
  -e TZ="America/New_York" \
  -e MARIADB_ROOT_PASSWORD="your_strong_password" \
  docker.mariadb.com/enterprise-server:11.8
```

Using `docker-compose.yml`

For deployments managed by Docker Compose, declare the `TZ` variable within the `environment` mapping of your service definition:

```
services:
  db:
    image: docker.mariadb.com/enterprise-server:11.8
    environment:
      - TZ=America/New_York
      - MARIADB_ROOT_PASSWORD=your_strong_password
```

Using `_FILE` Environment Variables for Secrets

When running Docker containers, it is a security best practice to avoid passing sensitive information, like database passwords, directly as plain-text environment variables. The MariaDB container images allow you to securely read secrets from mounted files by appending `_FILE` to the standard environment variable name.

List of supported `_FILE` Environment Variables

Name	Description
`MYSQL_ROOT_HOST_FILE`	Path to a file containing the host from which the root user is allowed to connect.
`MARIADB_ROOT_HOST_FILE`	Path to a file containing the host from which the root user is allowed to connect.

Name	Description
`MYSQL_DATABASE_FILE`	Path to a file containing the name of a database to be created on initialization.
`MARIADB_DATABASE_FILE`	Path to a file containing the name of a database to be created on initialization.
`MYSQL_USER_FILE`	Path to a file containing the username for a new user to be created on initialization.
`MARIADB_USER_FILE`	Path to a file containing the username for a new user to be created on initialization.
`MYSQL_PASSWORD_FILE`	Path to a file containing the password for the user defined by `MYSQL_USER`.
`MARIADB_PASSWORD_FILE`	Path to a file containing the password for the user defined by `MARIADB_USER`.
`MYSQL_ROOT_PASSWORD_FILE`	Path to a file containing the password for the root database user.
`MARIADB_ROOT_PASSWORD_FILE`	Path to a file containing the password for the root database user.
`MARIADB_PASSWORD_HASH_FILE`	Path to a file containing the hashed password for the created standard user.
`MARIADB_ROOT_PASSWORD_HASH_FILE`	Path to a file containing the hashed password for the root database user.
`MARIADB_UNIX_SOCKET_AUTHENTICATION_FILE`	Path to a file containing a value to enable/disable Unix socket authentication.
`MARIADB_REPLICATION_USER_FILE`	Path to a file containing the username to be used for setting up replication.
`MARIADB_REPLICATION_PASSWORD_FILE`	Path to a file containing the password for the replication user.
`MARIADB_REPLICATION_PASSWORD_HASH_FILE`	Path to a file containing the hashed password for the replication user.
`MARIADB_MASTER_HOST_FILE`	Path to a file containing the hostname or IP address of the replication master.
`MARIADB_MASTER_PORT_FILE`	Path to a file containing the port number of the replication master.

Example

Here is how to set up your MariaDB root password using the `MARIADB_ROOT_PASSWORD_FILE` environment variable.

Step 1: Create the Secret File

First, create a local file on your host machine that contains your desired environment variable. In this example, we will create a file named `mariadb_root_password_secret` containing the password `MariaDB11!`.

```
echo -n "MariaDB11!" > mariadb_root_password_secret
```

> **Note:**
>
> Using the `-n` flag with `echo` is highly recommended, as it ensures no hidden newline characters are accidentally appended to your password!

Step 2: Start the MariaDB Container

Next, run the container. You need to mount the local secret file into the container and set the environment variable to point to that newly mounted path.

```
docker run -d \
  -v "$(pwd)/mariadb_root_password_secret:/run/secrets/root_password" \
  -e MARIADB_ROOT_PASSWORD_FILE=/run/secrets/root_password \
  docker.mariadb.com/enterprise-server:11.8
```

Understanding the flags: * **`-v "$(pwd)/..."`**: This volume mount takes your local file (`mariadb_root_password_secret`) and securely maps it inside the container to `/run/secrets/root_password`. * **`-e MARIADB_ROOT_PASSWORD_FILE=...`**: This instructs the MariaDB initialization script to look inside `/run/secrets/root_password` and use its contents as the root password.

Step 3: Verify the Connection

Once the container is up and running, you can test the connection to ensure the password was applied correctly.

Grab your container ID (with `docker ps`) and use `docker exec` to start an interactive database session using the password you defined in Step 1:

```
docker exec -it <container_id> mariadb -u root -p'MariaDB11!'
```

If the secret was read successfully, you will be authenticated and greeted by the MariaDB:

```
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 5
```

Setting Up a LAMP Stack with Docker Compose

Docker Compose is a tool that allows one to declare which Docker containers should run, and which relationships should exist between them. It follows the **infrastructure as code** approach, just like most automation software and Docker itself.

For information about installing Docker Compose, see Install Docker Compose in Docker documentation.

The `docker-compose.yml` File

When using Docker Compose, the Docker infrastructure must be described in a YAML file called `docker-compose.yml`.

Let's see an example:

```
version: "3"

services:
  web:
    image: "apache:${PHP_VERSION}"
    restart: 'always'
    depends_on:
      - mariadb
    restart: 'always'
    ports:
      - '8080:80'
    links:
      - mariadb
  mariadb:
    image: "mariadb:${MARIADB_VERSION}"
    restart: 'always'
    volumes:
      - "/var/lib/mysql/data:${MARIADB_DATA_DIR}"
      - "/var/lib/mysql/logs:${MARIADB_LOG_DIR}"
      - /var/docker/mariadb/conf:/etc/mysql
    environment:
      MYSQL_ROOT_PASSWORD: "${MYSQL_ROOT_PASSWORD}"
      MYSQL_DATABASE: "${MYSQL_DATABASE}"
      MYSQL_USER: "${MYSQL_USER}"
      MYSQL_PASSWORD: "${MYSQL_PASSWORD}"
```

In the first line we declare that we are using version 3 of the Docker compose language.

Then we have the list of services, namely the `web` and the `mariadb` services.

Let's see the properties of the services:

Property	Description
`port`	Maps the 8080 container port to the 80 host system port; useful for development, allows browser connection to containerized web server.
`links`	Declares container connectivity, ensuring that the container can connect to `mariadb`. The hostname is the container name.
`depends_on`	Specifies that `mariadb` must start before `web`, ensuring the application can connect once MariaDB is ready.
`restart`	Ensures containers restart automatically if they crash (`restart: always`).
`volumes`	Creates accessible directories for containers on the host system, facilitating data persistence even if a container is destroyed.
`environment`	Sets environment variables within the container, crucial for defining MariaDB root credentials.

About Volumes

It is good practice to create volumes for:

- The data directory, so we don't lose data when a container is created or replaced, perhaps to upgrade MariaDB.
- The directory where we put all the logs, if it is not the datadir.
- The directory containing all configuration files (for development environments), so we can edit those files with the editor installed in the host system. Normally no editor is installed in containers. In production we don't need to do this, because we can copy files from a repository located in the host system to the containers.

Note that Docker Compose variables are just placeholders for values. Compose does not support assignment, conditionals or loops.

Using Variables

In the above example you can see several variables, like `${MARIADB_VERSION}`. Before executing the file, Docker Compose will replace this syntax with the `MARIADB_VERSION` variable.

Variables allow making Docker Compose files more reusable: in this case, we can use any MariaDB image version without modifying the Docker Compose file.

The most common way to pass variables is to write them into a file. This has the benefit of allowing us to version the variable file along with the Docker Compose file. It uses the same syntax you would use in BASH:

```
PHP_VERSION=8.0
MARIADB_VERSION=10.6
...
```

For bigger setups, it could make sense to use different environment files for different services. To do so, we need to specify the file to use in the Compose file:

```
services:
  web:
    env_file:
      - web-variables.env
...
```

Docker Compose Commands

Docker Compose is operated using `docker-compose`. Here we'll see the most common commands. For more commands and for more information about the commands mentioned here, see the documentation.

Docker Compose assumes that the Composer file is located in the current directory and it's called `docker-compose.yml`. To use a different file, the `-f <filename>` parameter must be specified.

Command	Description
`docker-compose pull`	Pulls the necessary images.
`docker-compose up --no-recreate`	Creates containers only if they do not already exist.
`docker-compose up`	Creates containers if they don't exist and recreates them if their image or configuration has changed.
`docker-compose up --force-recreate`	Recreates containers in all cases.
`docker-compose up --no-start`	Creates containers without starting them.
`docker-compose restart`	Restarts containers without recreating them.
`docker-compose kill <service>`	Kills a specific container by sending it a SIGKILL signal.
`docker-compose rm -f <service>`	Instantly removes a running container.
`docker-compose down`	Tears down all containers, networks, and volumes created by the Compose file.

Using Healthcheck

Using Healthcheck.sh

The healthcheck.sh script is part of the Docker Official Images of MariaDB Server. The script is part of the repository of the Docker Official Image of MariaDB Server.

The script processes a number of argument and tests, together, in strict order. Arguments pertaining to a test must occur before the test name. If a test fails, no further processing is performed. Both arguments and tests begin with a double-hyphen.

By default, (since 2023-06-27), official images will create `healthcheck@localhost`, `healthcheck@127.0.0.1`, `healthcheck@::1` users with a random password and USAGE privileges. MARIADB_HEALTHCHECK_GRANTS can be used for `--replication` where additional grants are required. This is stored in `.my-healthcheck.cnf` in the datadir of the container and passed as the `--defaults-extra-file` to the healthcheck.sh script if it exists. The `.my-healthcheck.cnf` also sets `protocol=tcp` for the `mariadb` so `--connect` is effectively there on all tests.

The MARIADB_AUTO_UPGRADE=1 will regenerate the `.my-healthcheck.cnf` file if missing and recreate the healthcheck users of the database with a new random password. The current port configuration of the MariaDB container is written into this file.

The MARIADB_MYSQL_LOCALHOST_USER=1, MARIADB_MYSQL_LOCALHOST_GRANTS environment variables can also be used, but with the creation of the healthcheck user, these are backwards compatible.

Compose File Example

An example of a compose file that uses the healthcheck.sh to determine a healthy service as a dependency before starting a WordPress service:

```
version: "3"
services:
  mariadb:

Tests

The various health check flags used for monitoring the status and readiness of a MariaDB server.

Health Check Flag	Description	Required Privileges
`--connect`	Active when an external user can connect to the TCP port of MariaDB Server. This strictly tests the TCP connection, not authentication.	
`--innodb_initialized`	True when InnoDB has completed initializing, including any rollback or crash recovery.	The connecting user must have `USAGE` privileges.
`--innodb_buffer_pool_loaded`	Indicates that the previously saved buffer pool dump has been completely loaded, meaning the server has a hot cache ready for use.	The connecting user must have `USAGE` privileges.
`--galera_online`	Indicates that the Galera node is online (based on the `wsrep_local_state` variable). This includes states like “joining” and “donor” where it cannot serve SQL queries.	The connecting user must have `USAGE` privileges.
`--replication`	Tests a replica based on the `--replication_*` parameters. All subtests must pass: - io: The IO thread is running. - sql: The SQL thread is running. - seconds_behind_master: The replica is less than a specified number of seconds behind the primary. - sql_remaining_delay: The delayed replica is less than a specified number of seconds behind the primary's execution.	`REPLICATION_CLIENT` (before MariaDB 10.5) or `REPLICA MONITOR` (MariaDB 10.5+).
`--mariadbupgrade`	Indicates that MariaDB is upgraded to the current version.	

Parameters

To customize the health checks described previously, you can use the following parameters:

Parameter	Description
`--replication_all`	Checks all replication sources.
`--replication_name=n`	Sets the multisource connection name to be tested. This unsets `--replication_all`.
`--replication_io`	Checks if the replication IO thread is running.
`--replication_sql`	Checks if the replication SQL thread is running.
`--replication_seconds_behind_master=n`	Checks if the replication delay is less than or equal to `n` seconds.
`--replication_sql_remaining_delay=n`	Checks if the remaining SQL delay is less than or equal to `n` seconds.
`--su=n`	Changes to the specified user (`n`). Can only be used once from the default `root` user.
`--su-mysql`	Changes to the `mysql` unix user. Respawns the script, resetting all parameters, so it should be the first argument.
`--datadir=n`	Specifies the data directory location (`n`) for the `--mariadbupgrade` test.
	These parameters are passed to the `mariadb` shell for all tests except `--mariadbupgrade`.

Examples

```
healthcheck.sh --su-mysql --connect --innodb_initialized
```

Switch to `mysql` user, and check if can connect and the innodb is initialized.

```
healthcheck.sh --su-mysql --connect --replication_io --replication_sql --
replication_seconds_behind_master=600  --replication_sql_remaining_delay=30 ----replication_name=archive
--replication --replication_seconds_behind_master=10  --replication_name=channel1 --replication
```

Switch to `mysql` user, check if connections can be made. For the replication channel `archive`, ensure IO and SQL threads are running, the seconds behind master is less than `600` seconds, and the SQL remaining delay is less than `30` seconds. For the `channel1`, the seconds behind master is limited to `10` seconds maximum.

MariaDB Enterprise Container Image Configuration Reference

Orchestrating a MariaDB Enterprise deployment within containerized environments involves more than just launching a database instance; it requires the precise alignment of server logic, intelligent traffic routing, and robust observability tools. This reference serves as the definitive technical roadmap for configuring the official images provided by the MariaDB Enterprise Docker Registry. It details the standardized environment variables, specialized sidecar patterns, and command-line flags required to transform raw images into a production-ready, cloud-native ecosystem.

MariaDB Enterprise Server (Standard and Tiered)

The MariaDB Enterprise Docker Registry provides Docker images for MariaDB Enterprise Server 10.6 and later. These images include standard storage engines such as InnoDB, Aria, MyISAM, and others by default.

Environment Variables

MariaDB Enterprise Server containers are primarily configured using environment variables during initialization:

- `MARIADB_ROOT_PASSWORD`: Specifies the password for the MariaDB `root` user. It can be set to a specific string, `RANDOM` to generate a password, or `EMPTY` for no password.
- `MARIADB_DATABASE`: If provided, the container creates this database on startup if it does not already exist.
- `MARIADB_USER` and `MARIADB_PASSWORD`: These must be used together to create a non-root user account with the specified credentials.
- `MARIADB_ROOT_HOST`: Defines the host from which the `root` user is allowed to connect, defaulting to `%` (any host).
- `MARIADB_UNIX_SOCKET_AUTHENTICATION`: When set to `1`, this enables Unix socket-based authentication for the root user, allowing passwordless access when connecting locally.
- `MARIADB_INITDB_SKIP_TZINFO`: Setting this to any non-empty value prevents the automatic loading of timezone data into the system tables.
- `SKIP_INIT_WSREP_OFF`: When set, the temporary server used during initialization is allowed to start with Galera Cluster replication (`wsrep`) enabled.

MariaDB Prometheus Exporter

> **Warning:**
>
> **Configuration Methodology**
> For optimal security and management, exporter configuration is executed via command-line flags or configuration files. Environment variables are utilized strictly for sensitive data, ensuring credentials remain protected from exposure in configuration logs.

The MariaDB Prometheus Exporter (based on `mysqld_exporter`) is a tool for scraping metrics from MariaDB instances.

Database Permissions

A dedicated database user is required to allow the exporter to scrape metrics:

```
CREATE USER 'exporter'@'localhost' IDENTIFIED BY 'XXXXXXXX' WITH MAX_USER_CONNECTIONS 3;
GRANT PROCESS, REPLICATION CLIENT, SELECT ON *.* TO 'exporter'@'localhost';
```

> Note: Limiting connections is recommended to prevent monitoring traffic from impacting server performance, though some versions like MariaDB 10.1 do not support resource limits.

Configuration and Usage

- Configuration File (`.my.cnf`): Credentials should be placed in a `[client]` section. The exporter reads this file from the current directory or a path specified by `--config.my-cnf`.
- Environment Variables: The `MYSQLD_EXPORTER_PASSWORD` variable can be used to provide the connection password securely.
- Collector Flags: Specific metric groups can be toggled using flags such as `--collect.binlog_size`, `--collect.engine_innodb_status`, and `--collect.info_schema.userstats`.
- Multi-Target Support: The exporter can act as a proxy for multiple MariaDB instances via the `/probe` endpoint using the `target` parameter. Authentication for different targets is managed using `auth_module` sections in the configuration file.

MaxScale Prometheus Exporter

> **Warning:**
>
> **Configuration Methodology**
> For optimal security and management, exporter configuration is executed via command-line flags or configuration files. Environment variables are utilized strictly for sensitive data, ensuring credentials remain protected from exposure in configuration logs.

The MaxScale Exporter collects metrics from the MaxScale REST API.

Prerequisites

- A MaxScale REST API user with read privileges must be created using `maxctrl`: `maxctrl create user monitor-user monitor-password`.

Configuration and Security

Configuration options follow a hierarchy where environment variables override command-line flags, which override configuration files.

- Environment Variables: Use `MAXSCALE_USERNAME` and `MAXSCALE_PASSWORD` to provide REST API credentials.
- Command Line Flags: Standard flags include `--maxscale-host`, `--maxscale-port` (default `8989`), and listener settings.
- TLS/SSL: Encrypted connections to MaxScale require the flags `--tls-ca-cert-file`, `--tls-private-key-file`, and `--tls-key-cert-file`. Use `--tls-insecure-skip-verify` for self-signed certificates.
- Encryption: The exporter can generate and use encrypted passwords via the `--secrets` and `--encrypt` flags.

MariaDB Enterprise nslcd Sidecar

The nslcd sidecar is utilized for integrating MariaDB with LDAP or Active Directory authentication through the Pluggable Authentication Module (PAM) framework.

Configuration Requirements

- `nslcd.conf`: This file configures the `nslcd` daemon, specifying the LDAP server URI, search base, and service account credentials (`binddn` / `bindpw`).
- Identity Management: The `nslcd` daemon must be configured to run as the `mysql` user and group (`uid mysql`, `gid mysql`).
- `nsswitch.conf`: This file determines the sources for name-service information and must include `ldap` for `passwd`, `group`, and `shadow` entries.
- Shared Socket: The daemon communicates with the MariaDB container via a shared Unix socket, typically mounted at `/var/run/nslcd`.

Integration with MariaDB

To enable this functionality, the MariaDB Custom Resource must be configured to load the `auth_pam` plugin using the `plugin_load_add` option in the `myCnf` section.

MaxScale and MaxScale Enterprise

The core MaxScale images do not rely on Docker-specific environment variables for internal configuration. Instead, MaxScale is configured using standard `.cnf` files or through the REST API. For monitoring deployments, it is paired with the MaxScale Prometheus Exporter as detailed above.

Kubernetes Operators for MariaDB

Operators basically instruct Kubernetes about how to manage a certain technology. Kubernetes comes with some default operators, but it is possible to create custom operators. Operators created by the community can be found on OperatorHub.io.

Custom Operators

Kubernetes provides a declarative API. To support a specific (i.e. MariaDB) technology or implement a desired behavior (i.e. provisioning a replica), we extend Kubernetes API. This involves creating two main components:

- A custom resource.
- A custom controller.

A custom resource adds an API endpoint, so the resource can be managed via the API server. It includes functionality to get information about the resource, like a list of the existing servers.

A custom controller implements the checks that must be performed against the resource to check if its state should be corrected using the API. In the case of MariaDB, some reasonable checks would be verifying that it accepts connections, replication is running, and a server is (or is not) read only.

MariaDB Enterprise Operator

MariaDB Enterprise Operator provides a seamless way to run and operate containerized versions of MariaDB Enterprise Server and MaxScale on Kubernetes, allowing you to leverage Kubernetes orchestration and automation capabilities. This document outlines the features and advantages of using Kubernetes and the MariaDB Enterprise Operator to streamline the deployment and management of MariaDB and MaxScale instances.

> **Tip:**
>
> Find the documentation here.

MariaDB Community Operator

mariadb-operator is a Kubernetes operator that allows you to run and operate MariaDB in a cloud native way. It aims to declaratively manage MariaDB instances using Kubernetes CRDs instead of imperative commands.

It's available in both Artifact Hub and Operator Hub and supports the following features:

- Easily provision standalone MariaDB servers in Kubernetes.
- Multiple highly available topologies supported:
  - Asynchronous replication
  - Synchronous multi-master via Galera
  - Multi-cluster: cross-cluster replication for multi-region deployments, disaster recovery, and blue-green upgrades.

    - MaxScale as database proxy to load balance requests and perform failover/switchover operations
- Flexible storage configuration. Volume expansion.
- Physical backups based on mariadb-backup and Kubernetes VolumeSnapshots.
- Logical backups based on mariadb-dump.
- Multiple backup storage types: S3 compatible, Azure Blob Storage, PVCs, Kubernetes volumes and `VolumeSnapshots`.
- Flexible backup configuration: scheduling, compression, encryption, retention policy, target policy, timeout, staging area…
- Target recovery time: restore the closest available backup to the specified time.
- Bootstrap new instances from: Physical backups, logical backups, S3, Azure Blob Storage, PVCs, `VolumeSnapshots`…
- Point-In-Time-Recovery: Archive binary logs to enable point-in-time restoration and significantly reduce RPO.
- Cluster-aware rolling update: roll out replica Pods one by one, wait for each of them to become ready, and then proceed with the primary Pod, using `ReplicasFirstPrimaryLast`.
- Zero-downtime blue-green updates: leverage the multi-cluster topology to maintain two identical cluster topologies, upgrade one in the background, and switch between them without downtime.
- Manual update strategies: `OnDelete` and `Never`.
- Automated data-plane updates.
- my.cnf change detection. Automatically trigger updates when my.cnf changes.
- Suspend operator reconciliation for maintenance operations.
- Maintenance mode for safe operational windows: cordon, drain connections, and read-only modes.
- Issue, configure and rotate TLS certificates and CAs.
- Automated root password rotation by updating the referenced `Secret`.
- Native integration with cert-manager. Automatically create `Certificate` resources.
- Prometheus metrics via mysqld-exporter and maxscale-exporter.
- Native integration with prometheus-operator. Automatically create `ServiceMonitor` resources.
- Declaratively manage SQL resources: users, grants and logical databases.
- Declaratively manage resources in external MariaDB instances.
- Configure connections for your applications.
- Orchestrate and schedule sql scripts.
- Validation webhooks to provide CRD immutability.
- Additional printer columns to report the current CRD status.
- CRDs designed according to the Kubernetes API conventions.
- Install it using helm, OLM or static manifests.
- Multiple deployment modes: cluster-wide and single namespace.
- Helm charts published as OCI artifacts.
- Helm chart to deploy MariaDB clusters and its associated CRs.
- Multi-arch distroless image.
- GitOps friendly.

Please, refer to the documentation, the API reference and the example suite for further detail.

Kubernetes Overview for MariaDB Users

Kubernetes, or K8s, is software to orchestrate containers. It is released under the terms of an open source license, Apache License 2.0.

Kubernetes was originally developed by Google. Currently it is maintained by the Cloud Native Computing Foundation (CNCF), with the status of Graduated Project.

For information about how to setup a learning environment or a production environment, see Getting started in Kubernetes documentation.

Architecture

Kubernetes runs in a **cluster**. A cluster runs a **workload**: a set of servers that are meant to work together (web servers, database servers, etc).

A Kubernetes cluster consists of the following components:

- Nodes run containers with the servers needed by our applications.
- Controllersconstantly check the cluster nodes current state, and compare it with the desired state.
- A Control Plane is a set of different components that store the cluster desired state and take decisions about the nodes. The Control Plane provides an API that is used by the controllers.

For more information on Kubernetes architecture, see Concepts and Kubernetes Components in Kubernetes documentation.

Nodes

A node is a system that is responsible to run one or more pods. A pod is a set of containers that run a Kubernetes workload or part of it. All containers that run in the same pod are also located on the same node. Usually identical pods run on different nodes for fault tolerance.

For more details, see Nodes in the Kubernetes documentation.

Every node must necessarily have the following components:

Component	Description
`kubelet`	`kubelet` has a set of `PodSpecs` which describe the desired state of pods. It checks that the current state of the pods matches the desired state. It especially takes care that containers don't crash.
`kube-proxy`	
`Container Runtime`	

Controllers

Controllers constantly check if there are differences between the pod's current state and their desired state. When differences are found, controllers try to fix them. Each node type controls one or more resource types. Several types of controllers are needed to run a cluster.

Most of the actions taken by the controllers user the API server in the Control Plane. However, this is not necessarily true for custom controllers. Also, some actions cannot be performed via the Control Plane. For example, if some nodes crashed, adding new nodes involves taking actions outside of the Kubernetes cluster, and controllers will have to do this themselves.

It is possible to write custom controllers to perform checks that require knowledge about a specific technology. For example, a MariaDB custom controller may want to check if replication is working by issuing SHOW REPLICA STATUS commands. This logic is specific to the way MariaDB works, and can only be implemented in a customer controller. Custom controllers are usually part of operators.

For more information, see Controllers in the Kubernetes documentation.

Control Plane

The control plane consists of the following components.

For more information about the control plane, see Control Plane Components in Kubernetes documentation.

API Server

An API Server exposes API functions both internally and externally. It is essential to coordinate Kubernetes components so that they react to node's change of state, and it allows the user to send commands.

The default implementation of the API Server is kube-apiserver. It is able to scale horizontally and to balance the load between its instances.

Component	Description
`kube-controller-manager`	Most controllers run in this component.
`etcd`	Contains all data used by a Kubernetes cluster. Taking regular backups of etcd data is advisable.
`kube-scheduler`	Decides which node should host a new pod based on criteria like resource requirements.
`cloud-controller-manager`	Implements logic and API of a cloud provider. Handles requests from the API Server and performs actions specific to a cloud vendor, like creating instances.

Clients and Tools

Kubernetes comes with a set of tools that allow us to communicate with the API server and test a cluster.

Tool	Description
`kubectl`	Enables communication with the API server and allows running commands on a Kubernetes cluster.
`kubeadm`	Facilitates the creation of a Kubernetes cluster ready to receive commands from kubectl.
`kind`	Used to create and manage test clusters on a personal machine. It creates a cluster consisting of Docker containers, requiring Docker to be installed. Available on Linux, MacOS, and Windows.
`minikube`	Runs a single-node cluster on the local machine. Available on Linux, MacOS, and Windows.

Vagrant and MariaDB

See Creating a Vagrantfile.

A guide on creating and configuring a `Vagrantfile` to define the characteristics of a MariaDB virtual machine, including box selection and provisioning steps.

See Vagrant Overview for MariaDB Users.

Introduction to Vagrant's workflow and terminology for database administrators, explaining how it simplifies the creation of reproducible MariaDB development environments.

See Vagrant Security.

Discusses security considerations when using Vagrant with MariaDB, such as default insecure keys, port forwarding risks, and ensuring production-grade settings are not used in dev boxes.

This page is licensed: CC BY-SA / Gnu FDL

Creating a Vagrantfile

In this page we discuss how to create a Vagrantfile, which you can use to create new boxes or machines. This content is specifically written to address the needs of MariaDB users.

A Basic Vagrantfile

A Vagrantfile is a Ruby file that instructs Vagrant to create, depending on how it is executed, new Vagrant machines or boxes. You can see a box as a compiled Vagrantfile. It describes a type of Vagrant machines. From a box, we can create new Vagrant machines. However, while a box is easy to distribute to a team or to a wider public, a Vagrantfile can also directly create one or more Vagrant machines, without generating any box.

Here is a simple Vagrantfile example:

```
Vagrant.configure("2") do |config|
  config.vm.box = "hashicorp/bionic64"
  config.vm.provider "virtualbox"
  config.vm.provision :shell, path: "bootstrap.sh"
end
```

`Vagrant.configure("2")` returns the Vagrant configuration object for the new box. In the block, we'll use the `config` alias to refer this object. We are going to use version 2 of Vagrant API.

`vm.box` is the base box that we are going to use. It is Ubuntu BionicBeaver (18.04 LTS), 64-bit version, provided by HashiCorp. The schema for box names is simple: the maintainer account in Vagrant Cloud followed by the box name.

We use `vm.provision` to specify the name of the file that is going to be executed at the machine creation, to provision the machine. `bootstrap.sh` is the conventional name used in most cases.

To create new Vagrant machines from the Vagrantfile, move to the directory that contains the Vagrant project and run:

```
vagrant up
```

To compile the Vagrantfile into a box:

```
vagrant package
```

These operations can take time. To preventively check if the Vagrantfile contains syntax errors or certain types of bugs:

```
vagrant validate
```

Providers

A provider allows Vagrant to create a Vagrant machine using a certain technology. Different providers may enable a virtual machine manager (VirtualBox, VMWare, Hyper-V…), a container manager (Docker), or remote cloud hosts (AWS, Google Compute Engine…).

Some providers are developed by third parties. app.vagrant.com supports search for boxes that support the most important third parties providers. To find out how to develop a new provider, see Plugin Development: Providers.

Provider options can be specified. Options affect the type of Vagrant machine that is created, like the number of virtual CPUs. Different providers support different options.

It is possible to specify multiple providers. In this case, Vagrant will try to use them in the order they appear in the Vagrantfile. It will try the first provider; if it is not available it will try the second; and so on.

Here is an example of providers usage:

```
Vagrant.configure("2") do |config|
    config.vm.box = "hashicorp/bionic64"
    config.vm.provider "virtualbox" do |vb|
        vb.customize ["modifyvm", :id, "--memory", 1024 * 4]
    end
    config.vm.provider "vmware_fusion"
end
```

In this example, we try to use VirtualBox to create a virtual machine. We specify that this machine must have 4G of RAM (1024M * 4). If VirtualBox is not available, Vagrant will try to use VMWare.

This mechanism is useful for at least a couple of reasons:

- Different users may use different systems, and maybe they don't have the same virtualization technologies installed.
- We can gradually move from one provider to another. For a period of time, some users will have the new virtualization technology installed, and they will use it; other users will only have the old technology installed, but they will still be able to create machines with Vagrant.

Provisioners

We can use different methods for provisioning. The simplest provisioner is `shell`, that allows one to run a Bash file to provision a machine. Other provisioners allow setting up the machines using automation software, including Ansible, Puppet, Chef and Salt.

To find out how to develop a new provisioner, see Plugin Development: Provisioners.

The `shell` Provisioner

In the example above, the shell provisioner runs bootstrap.sh inside the Vagrant machine to provision it. A simple bootstrap.sh may look like the following:

```
#!/bin/bash

apt-get update
apt-get install -y
```

To find out the steps to install MariaDB on your system of choice, see the Getting, Installing, and Upgrading MariaDB section.

You may also want to restore a database backup in the new Vagrant machine. In this way, you can have the database needed by the application you are developing. To find out how to do it, see Backup and Restore Overview. The most flexible type of backup (meaning that it works between different MariaDB versions, and in some cases even between MariaDB and different DBMSs) is a dump.

On Linux machines, the `shell` provisioner uses the default shell. On Windows machines, it uses PowerShell.

Uploading Files

If we use the `shell` provisioner, we need a way to upload files to the new machine when it is created. We could use the `file` provisioner, but it works by connecting the machine via ssh, and the default user doesn't have permissions for any directory except for the synced folders. We could change the target directory owner, or we could add the default user to a group with the necessary privileges, but these are not considered good practices.

Instead, we can just put the file we need to upload somewhere in the synced folder, and then copy it with a shell command:

```
cp ./files/my.cnf /etc/mysql/conf.d/
```

Provisioning Vagrant with Ansible

Here is an example of how to provision a Vagrant machine or box by running Ansible:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "ansible" do |ansible|
    ansible.playbook = "vagrant.yml"
  end
end
```

With the Ansible provisioner, Ansible runs in the host system and applies a playbook in the guest system. In this example, it runs a playbook called `vagrant.yml`. The Ansible Local provisioner runs the playbook in the vagrant machine.

For more information, see Using Vagrant and Ansible in the Ansible documentation. For an introduction to Ansible for MariaDB users, see Ansible and MariaDB.

Provisioning Vagrant with Puppet

To provision a Vagrant machine or box by running Puppet:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet" do |puppet|
    puppet.manifests_path = "manifests"
    puppet.manifest_file = "default.pp"
  end
end
```

In this example, Puppet Apply runs in the host system and no Puppet Server is needed. Puppet expects to find a `manifests` directory in the project directory. It expects it to contain `default.pp`, which will be used as an entry

point. Note that `puppet.manifests_path` and `puppet.manifest_file` are set to their default values.

Puppet needs to be installed in the guest machine.

To use a Puppet server, the `puppet_server` provisioner can be used:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet_server" do |puppet|
    puppet.puppet_server = "puppet.example.com"
  end
end
```

See the Puppet Apply provisioner and the Puppet Agent Provisioner.

For an introduction to Puppet for MariaDB users, see Puppet and MariaDB.

Sharing Files Between the Host and a Guest System

To restore a backup into MariaDB, in most cases we need to be able to copy it from the host system to the box. We may also want to occasionally copy MariaDB logs from the box to the host system, to be able to investigate problems.

The project directory (the one that contains the Vagrantfile) by default is shared with the virtual machine and mapped to the `/vagrant` directory (the synced folder). It is a good practice to put there all files that should be shared with the box when it is started. Those files should normally be versioned.

The synced folder can be changed. In the above example, we could simply add one line:

```
config.vm.synced_folder "/host/path", "/guest/path"
```

The synced folder can also be disabled:

```
config.vm.synced_folder '.', '/vagrant', disabled: true
```

Note that multiple Vagrant machines may have synced folders that point to the same directory on the host system. This can be useful in some cases, if you prefer to test some functionalities quickly, rather that replicating production environment as faithfully as possible. For example, to test if you're able to take a backup from one machine and restore it to another, you can store the backup in a common directory.

Network Communications

It is often desirable for a machine to be able to communicate with "the outside". This can be done in several ways:

- Private networks;
- Public networks;
- Exposing ports to the host.

Remember that Vagrant doesn't create machines itself; instead, it asks a provider to create and manage them. Some providers support all of these communication methods, while others may only support some of them, or even none at all. When you create a Vagrantfile that uses one of these networking features, it is implicit that this can only happen if the provider you are using supports them. Check your provider's documentation to find out which features it supports.

The default provider, VirtualBox, supports all of these communication methods, including multiple networks.

Private Networks

A private network is a networks that can only be accesses by machines that run on the same host. Usually this also means that the machines must run on the same provider (for example, they all must be VirtualBox virtual machines).

Some providers support multiple private networks. This means that every network has a different name and can be accessed by different machines.

The following line shows how to create or join a private network called “example”, where this machine’s IP is assigned by the provider via DHCP:

```
config.vm.network 'private_network', name: 'example', type: 'dhcp'
```

While this is very convenient to avoid IP conflicts, sometimes you prefer to assign some IP’s manually, in this way:

```
config.vm.network 'private_network', name: 'example', ip: '111.222.111.222'
```

Public Networks

As explained above, public networks are networks that can be accessed by machines that don’t run on the same host with the same provider.

To let a machine join a public network:

```
# use provider DHCP:
config.vm.network "public_network", use_dhcp_assigned_default_route: true

# assign ip manually:
config.vm.network "public_network", ip: "111.222.111.222"
```

To improve security, you may want to configure a gateway:

```
config.vm.provision "shell", run: "always", inline: "route add default gw 111.222.111.222"
```

Exposing Ports

Vagrant allows us to map a TCP or UDP port in a guest system to a TCP or UDP port in the host system. For example, you can map a virtual machine port 3306 to the host port 12345. Then you can connect MariaDB in this way:

```
mariadb -hlocalhost -P12345 -u<user> -p<password>
```

You are not required to map a port to a port with a different number. In the above example, if the port 3306 in your host is not in use, you are free to map the guest port 3306 to the host port 3306.

There are a couple of caveats:

- You can’t map a single host port to multiple guest ports. If you want to expose the port 3306 from multiple Vagrant machines, you’ll have to map them to different host ports. When running many machines this can be hard to maintain.
- Ports with numbers below 1024 are privileged ports. Mapping privileged ports requires root privileges.

To expose a port:

```
config.vm.network 'forwarded_port', guest: 3306, host: 3306
```

Use Cases

Suppose you run MariaDB and an application server in two separate Vagrant machines. It's usually best to let them communicate via a private network, because this greatly increases your security. The application server will still need to expose ports to the host, so the application can be tested with a web browser.

Suppose you have multiple environments of the same type, like the one described above. They run different applications that don't communicate with each other. In this case, if your provider supports this, you will run multiple private networks. You will need to expose the applications servers ports, mapping them to different host ports.

You may even want to implement different private networks to create an environment that reflects production complexity. Maybe in production you have a cluster of three MariaDB servers, and the application servers communicate with them via a proxy layer (ProxySQL, HAProxy, or MaxScale). So the applications can communicate with the proxies, but have no way to reach MariaDB directly. So there is a private network called "database" that can be accessed by the MariaDB servers and the proxy servers, and another private network called "application" that can be accessed by the proxy servers and the application servers. This requires that your provider supports multiple private networks.

Using public networks instead of private one will allow VMs that run on different hosts to be part of your topology. In general this is considered as an insecure practice, so you should probably ask yourself if you really need to do this.

Vagrant Overview for MariaDB Users

Vagrant is a tool to create and manage development machines (Vagrant *boxes*). They are usually virtual machines on the localhost system, but they could also be Docker containers or remote machines. Vagrant is open source software maintained by HashiCorp and released under the MIT license.

Vagrant benefits include simplicity, and a system to create test boxes that is mostly independent from the technology used.

For information about installing Vagrant, see Installation in Vagrant documentation.

In this page we discuss basic Vagrant concepts.

Vagrant Concepts

Following are the core Vagrant concepts:

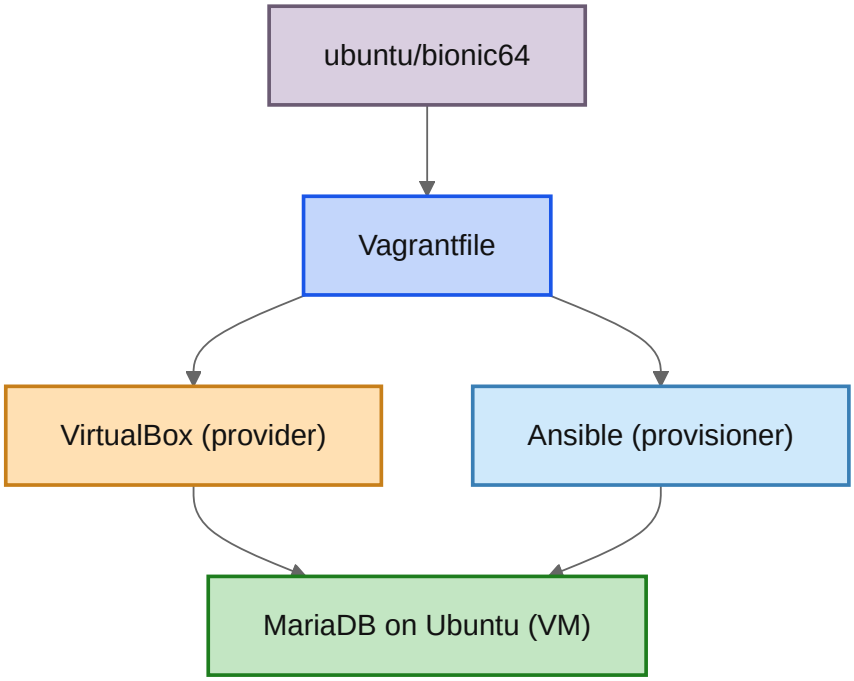
Concept	Description
Vagrant Machine	The final environment created from a box. It can be a virtual machine, a container, or a remote cloud server.
Box	A reusable package used to create Vagrant machines. It can be a base OS image downloaded from Vagrant Cloud or a custom-built template.
Provider	The underlying virtualization technology that runs the machine (e.g., VirtualBox, VMware, Hyper-V, Docker).
Provisioner	A tool or script (e.g., Shell, Ansible, Puppet) that automatically installs and configures software on the machine after it is created.

Example

The above concepts are probably easier to understand with an example.

We can use an Ubuntu box as a base to build a Vagrant machine with MariaDB. So we write a Vagrantfile for this purpose. In the Vagrantfile we specify VirtualBox as a provider. And we use the Ansible provisioner to install and configure MariaDB. Once we finish this Vagrantfile, we can run a Vagrant command to start a Vagrant machine, which is actually a VirtualBox VM running MariaDB on Ubuntu.

The following diagram should make the example clear:



Vagrant builds a machine from the ubuntu/bionic64 box using a Vagrantfile, which selects VirtualBox as the provider and Ansible as the provisioner to install MariaDB on the resulting VM.

Vagrantfiles

A Vagrantfile is a file that describes how to create one or more Vagrant machines. Vagrantfiles use the Ruby language, as well as objects provided by Vagrant itself.

A Vagrantfile is often based on a box, which is usually an operating system in which we are going to install our software. For example, one can create a MariaDB Vagrantfile based on the `ubuntu/trusty64` box. A Vagrantfile can describe a box with a single server, like MariaDB, but it can also contain a whole environment, like LAMP. For most practical use cases, having the whole environment in a single box is more convenient.

Boxes can be searched in Vagrant Cloud. Most of their Vagrantfiles are available on GitHub. Searches can be made, among other things, by keyword to find a specific technology, and by provider.

Providers

A provider adds support for creating a specific type of machines. Vagrant comes with several providers, for example:

- `VirtualBox` allows one to create virtual machines with VirtualBox.
- `Microsoft-Hyper-V` allows one to create virtual machines with Microsoft Hyper-V.
- Docker allows one to create Docker containers. On non-Linux systems, Vagrant will create a VM to run Docker.

Alternative providers are maintained by third parties or sold by HashiCorp. They allow one to create different types of machines, for example using VMWare.

Some examples of useful providers, recognized by the community:

- Vagrant AWS Provider.
- Vagrant Google Compute Engine (GCE) Provider.
- Vagrant Azure Provider.
- OpenVZ.
- vagrant-lxc.

If you need to create machines with different technologies, or deploy them to unsupported cloud platforms, you can develop a custom provider in Ruby language. To find out how, see Plugin Development: Providers in Vagrant documentation. The Vagrant AWS Provider was initially written as an example provider.

Provisioners

A provisioner is a technology used to deploy software to the newly created machines.

The simplest provisioner is `shell`, which runs a shell file inside the Vagrant machine. `powershell` is also available.

Other providers use automation software to provision the machine. There are provisioners that allow one to use Ansible, Puppet, Chef or Salt. Where relevant, there are different provisioners allowing the use of these technologies in a distributed way (for example, using Puppet apply) or in a centralized way (for example, using a Puppet server).

It is interesting to note that there is both a Docker provider and a Docker provisioner. This means that a Vagrant machine can be a Docker container, thanks to the `docker` provisioner. Or it could be any virtualisation technology with Docker running in it, thanks to the `docker` provisioner. In this case, Docker pulls images and starts containers to run the software that should be running in the Vagrant machine.

If you need to use an unsupported provisioning method, you can develop a custom provisioner in Ruby language. See Plugin Development: Provisioners in Vagrant documentation.

Plugins

It is possible to install a plugin with this command:

```
vagrant plugin install <plugin_name>
```

A Vagrantfile can require that a plugin is installed in this way:

```
require 'plugin_name'
```

A plugin can be a Vagrant plugin or a Ruby gem installable from rubygems.org. It is possible to install a plugin that only exists locally by specifying its path.

Changes in Vagrant 3.0

HashiCorp published an article that describes its plans for Vagrant 3.0.

Vagrant will switch to a client-server architecture. Most of the logic will be stored in the server, while the development machines will run a thin client that communicates with the server. It will be possible to store the configuration in a central database.

Another notable change is that Vagrant is switching from Ruby to Go. For some time, it will still be possible to use Vagrantfiles and plugins written in Ruby. However, in the future Vagrantfiles and plugins should be written in one of the languages that support gRPC (not necessarily Go). Vagrantfiles can also be written in HCL, HashiCorp Configuration Language.

Vagrant Commands

This is a list of the most common Vagrant commands. For a complete list, see Command-Line Interface in Vagrant documentation.

To list the available machines:

```
vagrant box list
```

To start a machine from a box:

```
cd /box/directory
vagrant up
```

To connect to a machine:

```
vagrant ssh
```

To see all machines status and their id:

```
vagrant global-status
```

To destroy a machine:

```
vagrant destroy <id>
```

Vagrant Security

Databases typically contain information to which access should be restricted. For this reason, it's worth discussing some security concerns that Vagrant users should be aware of.

Access to the Vagrant Machine

By default, Vagrant machines are only accessible from the localhost. SSH access uses randomly generated key pairs, and therefore it is secure.

The password for `root` and `vagrant` is “vagrant” by default. Consider changing it.

Synced Folders

By default, the project folder in the host system is shared with the machine, which sees it as `/vagrant`. This means that whoever has access to the project folder also has read and write access to the synced folder. If this is a problem, make sure to properly restrict the access to the synced folder.

If we need to exchange files between the host system and the Vagrant machine, it is not advisable to disable the synced folder. This is because the only alternative is to use the `file` provider, which works by copying files to the machine via ssh. The problem is that the default ssh user does not have permissions to write to any directory by default, and changing this would be less secure than using a synced folder.

When a machine is provisioned, it should read the needed files from the synced folder or copy them to other places. Files in the synced folder should not be accessed by the Vagrant machine during its normal activities. For example, it is fine to load a dump from the synced folder during provisioning; and it is fine to copy configuration files from the synced folder to directories in `/etc` during provisioning. But it is a bad practice to let MariaDB use table files located in the synced folder.

Reporting Security Bugs

Note that security bugs are not reported as normal bugs. Information about security bugs are not public. See Security at HashiCorp for details.

Overview of MariaDB Logs

There are many variables in MariaDB that you can use to define what to log and when to log.

This page will give you an overview of the different logs and how to enable/disable logging to these.

> **Note:**
>
> Storage engines and plugins can have their logs too. For example, InnoDB keeps an Undo Log and a Redo Log which are used for rollback and crash recovery. However, this page only lists MariaDB server logs.

Standardized Log Naming

Use the –log-basename startup setting to establish a common base name for all log files. This option configures the base name for the *Error Log*, *General Query Log*, *Slow Query Log*, and *Binary Log* simultaneously. Using a standardized base name ensures consistency across different logs and simplifies management in multi-instance or clustered environments.

Error Log

- Always enabled by default.
- Records all critical errors encountered by the server.
  - Useful for diagnosing startup failures, crashes, and internal server errors.
- Can be configured to record varying levels of warnings and notes.

General Query Log

- Records a record of when clients connect or disconnect, and every SQL statement received from clients.
- Useful for debugging queries and monitoring client activity.

- For security and compliance auditing, use the MariaDB Audit Plugin or MariaDB Enterprise Audit instead.

Slow Query Log

- Records all SQL queries that take more than a defined threshold of time to execute.
- Useful for identifying performance bottlenecks and queries that require optimization.
- Can be filtered or sampled to reduce log volume on high-traffic servers.

Binary Log

- Records all statements that change data (DML and DDL) in a binary format.
- Essential for replication topologies where the server acts as a primary.
- Required for point-in-time recovery and database restoration.

Parsing Reference for Tool Developers

To support the development of log parsers (e.g., Fluentd, Logstash, Splunk), the following tables standardize identification fields and structural characteristics across all MariaDB Server logs.

Cross-Log Field Standardization

The following data points are represented differently across various logs but refer to the same internal identifiers.

Standardized Name	General/Slow Log Field	Audit Log Field	Error Log Field	Binary Log (Text)
Thread ID	`thread_id`	`connectionid`	`Thread ID`	`at {ID}`
Server ID	`server_id`	N/A (Uses Hostname)	N/A (Uses Process ID)	`server id`

Structural Characteristics for Parsers

Log Type	Primary Format	Record Start Indicator	Multi-line Support
Error Log	Positional String	Timestamp (`YYYY-MM-DD`)	No (Except Stack Traces)
General Query Log	Positional String	Timestamp	Yes (SQL Payloads)
Slow Query Log	Tagged Header	`# User@Host:`	Yes (Always)
Binary Log (Text)	Tagged Header	`# at {Position}`	Yes (Event Chunks)
Enterprise Audit	CSV	N/A (Standard Line)	No

Parser Developer Checklist

- Handle Multi-line Records: Assume that General and Slow Query logs will contain newlines within SQL statements.
- Standardize Identifiers: Always map `connectionid` and `thread_id` to a single `thread_id` field in your monitoring backend to allow cross-log correlation.
- Identify Record Starts: For Slow Query logs, use `# User@Host:` as the only reliable indicator of a new record.

This page is licensed: CC BY-SA / Gnu FDL

Securing MariaDB Logs

Introduction

In any hardened database environment, logs are more than just a diagnostic tool; they are a critical trail of evidence and a blueprint of your data's movement. Ensuring the security of these logs is paramount for maintaining data integrity, achieving regulatory compliance (such as GDPR or HIPAA), and performing effective forensic analysis in the event of a breach.

Log security involves protecting data in two distinct states:

- Data-at-Rest: Preventing unauthorized users or malicious actors from reading or tampering with log files stored on the disk.
- Data-in-Transit: Ensuring that when logs are moved—specifically during replication—they cannot be intercepted or spoofed.

Built-in Security Mechanisms

MariaDB provides several native features to help you secure this information:

- Access Control: Replication relies on a strictly defined username and password. Both the primary and the replica require specific privileges (`REPLICATION REPLICA`) to transfer, receive, and read log data.
- Native Encryption: You can protect the contents of your binary logs and relay logs at the storage level by enabling the `encrypt_binlog=ON` system variable.
- Database Table Security: While this guide focuses on file-based logging, MariaDB allows the General and Slow Query logs to be written to internal database tables. When logged to tables, these records inherit the same robust security, backup, and access control (via `GRANT` statements) as any other data in your database.
- On Linux, specifying `log_error` without a log file location is secure by default, because the systemd journal is used. See this section for context.

Log File Locations

By default, MariaDB log files are located within the Data Directory (`datadir`; often `/var/lib/mysql/` on Linux systems). However, for both security and performance reasons, it is common practice to move these files to a dedicated, restricted volume.

This page focuses on the security of log *files*, providing best practices for file system permissions, encryption, and rotation strategies to ensure your “digital paper trail” remains uncompromised.

To control where logs are written, MariaDB uses the global system variable `log_output`. The possible values are:

- `FILE`: (Default) Logs to a file.
- `TABLE`: Logs to the `mysql.general_log` and `mysql.slow_log` tables.
- `NONE`: Disables logging even if the logs are globally enabled.
- `FILE,TABLE`: Logs to both destinations simultaneously.

Table logging can be enabled for these log types:

1. General Query Log: This logs all established client connections and all statements received from clients. Table logging uses the CSV storage engine by default. However, this can be changed; see Writing Logs Into Tables.
2. Slow Query Log: This logs all SQL statements that took more than `long_query_time` seconds to execute and required at least `min_examined_row_limit` rows to be examined. Table logging uses the CSV storage engine by default. However, this can be changed; see Writing Logs Into Tables.
3. Binary Log (as of MariaDB 12.3): See InnoDB-Based Binary Log.

Since MariaDB is cross-platform, securing the physical log files requires a “defense-in-depth” approach tailored to each operating system’s permission model. The goal is the same across all platforms: only the MariaDB service account should have read/write access, and only authorized administrators should have read access.

Implementation Pro-Tip: The Principle of Least Privilege

When setting up these logs, always remember that the MariaDB Service Account (for instance, `mysql` or `NT Service\MariaDB`) is the only entity that needs write access. Human administrators should only have read access, and only when necessary for troubleshooting.

Summary of This Guide

By following this guide, you move from default, “open” logging to a hardened architecture:

- Logs are isolated on a dedicated partition.
- Access is restricted via OS-level permissions.
- Content is encrypted both on disk and over the wire.
- Retention is automated to prevent disk exhaustion.
- Activity is audited to detect tampering.

Log Security Best Practices in a Nutshell

If you only have five minutes to harden your MariaDB logging environment, focus on these five pillars:

- Isolation: Move all log files (`log_error` , `general_log_file` , etc.) out of the default data directory and onto a dedicated, encrypted partition to prevent “Disk Full” stalls and unauthorized access.
- Encryption: Enable `encrypt_binlog = ON` to protect your data-at-rest and enforce `require_secure_transport = ON` to ensure log data-in-transit (replication) is wrapped in TLS/SSL.
  As of MariaDB 11.4, TLS is enabled, even on a replication connection, by default (certificate-free TLS).
- Least Privilege: Restrict file-system permissions so that only the MariaDB service account can write to logs, and only high-level administrators can read them.
- Automated Rotation: Use `logrotate` (Linux) or scripts (Windows) for file-based logs, and `binlog_expire_logs_seconds` for binary logs to ensure you don’t run out of storage.
- Integrity Monitoring: Use the MariaDB Audit Plugin to log any attempts to disable logging or modify security-sensitive system variables.

Key Configuration Quick-Reference

Feature	Variable / Tool	Recommended Setting
At-Rest Encryption	`encrypt_binlog`	`ON`
In-Transit Security	`require_secure_transport`	`ON`
Linux Permissions	`chmod`	`660` for files; `750` for dirs
Log Retention	`binlog_expire_logs_seconds`	`604800` (7 Days)
Auditing	`server_audit_events`	`CONNECT, QUERY, TABLE`

Securing Log Files at the OS Level

LINUX

On Linux, the MariaDB process usually runs under a dedicated `mysql` user and group.

- Ownership: Ensure the data directory and log files are owned by the `mysql` user.
  - `chown -R mysql:mysql /var/lib/mysql`
- Permissions: Use restrictive octal permissions. Log files should generally be `660` (read/write for user/group, nothing for others) and directories should be `750` .
  - `chmod 660 /var/lib/mysql/mariadb.log`
- AppArmor/SELinux: If your distribution uses these, ensure policies are defined so that even if the MariaDB process is compromised, it cannot write logs to unauthorized locations (like `/tmp`).

WINDOWS

Windows uses Access Control Lists (ACLs) which are more granular than Linux permissions.

- Service Account: MariaDB typically runs as `NetworkService` or a specific local user.
- Inheritance: Disable permission inheritance on the `data` folder to prevent “Authenticated Users” from browsing your logs.
- Configuration:
  1. Right-click the log folder > Properties > Security > Advanced.
  2. Remove *Everyone* and *Users*.
  3. Add the specific MariaDB service account with Full Control.
  4. Add Administrators with Read/Execute.

MACOS

macOS follows a Unix-like permission structure similar to Linux, though the default user might be your local username if installed via Homebrew.

- Homebrew Path: Logs are often in `/opt/homebrew/var/mysql/`.
- Hardening: Use `chmod 700` on the log directory to ensure other local user accounts on the Mac cannot peek at your query history (which might contain sensitive data in plain text).

Sanitization of Backups

Logs are often backed up alongside data.

- Redaction: Be mindful that logs converted to `.sql` files for auditing (see this example) are now plain text and need to be deleted or encrypted immediately after use.
- Retention: Implement an automated purge policy (`expire_logs_days`) to ensure sensitive data does not persist on disk longer than legally or operationally required.

Changing the Log Location

As mentioned in the introduction, keeping logs on the same partition as your data is a security and availability risk (for instance, a “log bomb” filling up the disk and crashing the database).

To change the location, edit your `my.cnf` or `my.ini` file:

```
[mariadb]
# Example: Moving the Error Log
log_error = /var/log/mariadb/error.log

# Example: Moving the General Log
general_log_file = /var/log/mariadb/general.log
```

Note:

When moving logs on Linux, you must manually create the new directory and set the ownership to `mysql` before restarting the service, or MariaDB will fail to start due to “Permission Denied.”

Note:

On **Linux**, adding `log_error` without specifying a location logs to the `systemd` journal. This is a viable alternative to the above, and even more secure than a log file on disk, since it cannot be changed by the MariaDB process.

Because logs can grow indefinitely, an unmanaged log file is a security risk—not just for data exposure, but as a Denial of Service (DoS) vector. If a log file fills the storage partition, the MariaDB server will crash or hang.

Log Rotation and Retention Strategies

Log rotation is the process of periodically archiving the current log file and starting a fresh one. This limits the size of individual files and allows for the automatic deletion of old data after a set period.

LINUX

Linux: Using `logrotate`

On Linux, the standard way to handle this is the `logrotate` utility. It allows you to compress old logs (saving space) and set a retention policy (for instance, keep only the last 30 days).

A typical MariaDB `logrotate` configuration (usually found in `/etc/logrotate.d/mariadb`) looks like this:

```
/var/lib/mysql/*.log {
    daily
    rotate 30
    missingok
    compress
    sharedscripts
    postrotate
        # Tell MariaDB to close and reopen log files
        mariadb-admin --local flush-error-log  flush-engine-log flush-general-log flush-slow-log
    endscript
}
```

- `compress`: Encrypting logs is good, but compressing them is essential for storage.
- `postrotate`: This is critical. MariaDB holds a file handle on the log. If you move the file without telling MariaDB, it will keep writing to the old (now renamed) file. `flush-logs` forces it to start writing to the new filename.

WINDOWS

Windows: Scripted Rotation

Windows does not have a native `logrotate` equivalent. Most administrators use a PowerShell script triggered by the Task Scheduler.

A basic security workflow for Windows logs:

1. Stop Logging: Briefly disable the log via SQL (`SET GLOBAL general_log = 'OFF';`).
2. Rename: Move `mariadb.log` to `mariadb_2026_02_25.log`.
3. Start Logging: Re-enable logging; MariaDB will automatically create a new, empty file.
4. Archive: Move the old file to a secure, long-term storage volume with restricted NTFS permissions.

INTERNAL ROTATION (BINARY LOGS)

MariaDB Internal Rotation (Binary Logs)

The Binary Log is unique because MariaDB manages its rotation internally. You should never use external tools like `logrotate` on binary logs, as it will break replication.

Instead, use these system variables in your configuration file:

- `max_binlog_size`: Defines the threshold at which a new file is created (default is 1GB).
- `binlog_expire_logs_seconds`: Defines how long (in seconds) MariaDB keeps binary logs before automatically deleting them.

Security Best Practices for Rotated Logs

- Off-site Logging: For high-security environments, don't just rotate logs locally. Use a logging agent (like Fluentd or Logstash) to stream logs to a centralized, hardened log server or a SIEM (Security Information and Event Management) system.
  On Linux, an alternative is to log to systemd-journal-remote.
- Read-Only Archives: Once a log file is rotated/archived, change its permissions to Read-Only. There is no reason for the MariaDB process to have write access to a log from last month.
- Checksums: Periodically generate SHA-256 checksums of archived logs. This allows you to prove in an audit that the logs have not been tampered with since they were rotated.

Securing Binary Log Files

Generally, the same security concepts and measures apply as for other log files. Here are some extra notes on binary log files and relay log files.

Encryption at Rest

If your disk is compromised or a backup of the logs is stolen, raw binary logs are vulnerable.

- MariaDB Encryption: Enable the built-in MariaDB transparent encryption for binary logs. This ensures that even if someone copies a binary log file, they cannot decode it without the encryption keys.
- See detailed instructions for encrypting binary logs.

Securing Logs in Transit

When a replica connects to a primary server, it "pulls" binary log events. Without encryption, these events (which contain your raw SQL data) travel across the network in plain text.

Beyond the standard "use a strong password," there are three specific MariaDB security features you should definitely include to ensure log data isn't intercepted or faked during transmission.

> **Note:**
>
> SSL/TLS: Always use encrypted connections for replication traffic to prevent "sniffing" of the log data as it moves across the network.

Mandatory TLS/SSL for Replication

The most critical step is ensuring the log data is wrapped in an encrypted tunnel. You can enforce this on the primary server so it rejects any replica trying to connect without a secure certificate.

- Set `require_secure_transport = ON` globally, or specifically for the replication user:

  ```
  ALTER USER 'repl_user'@'%' REQUIRE SSL;
  ```

- This prevents "Man-in-the-Middle" (MITM) attacks where an attacker on the network could sniff the binary log stream to steal sensitive data.

Binary Log Checksums

While encryption protects against *reading* the logs, checksums protect against *corruption* or *tampering* during the transfer.

- In your configuration file (`my.cnf` or `my.ini`), set the `binlog_checksum` variable: `binlog_checksum = CRC32`
- With that setting, the primary calculates a CRC32 hash for every event in the binary log. The replica verifies this hash before applying the event. If a packet is altered or corrupted during transit, the replica stops and reports an

error rather than writing “junk” or malicious data to its database.

Master Key Rotation (for Encrypted Logs)

If you have enabled `encrypt_binlog = ON`, you must consider how the encryption keys are handled during replication.

- Only the *file* is encrypted on disk. When the log is read to be sent to a replica, it is decrypted by the primary and then re-encrypted by the network protocol (TLS).
- Security Tip: Ensure you are using a robust Key Management Service (KMS) plugin (like the AWS, HashiCorp Vault, or File Key Management plugins). Regularly rotating the Master Key ensures that, even if an old archived log file and an old key were somehow compromised, the current “live” logs remain secure.

Replica Side: Securing the Relay Log

Once the log data arrives at the replica, it is stored in Relay Logs before being executed.

- Security Risk: The replica’s relay logs are just as sensitive as the primary’s binary logs.
- Ensure `encrypt_binlog = ON` is also set on the replica. This ensures that the moment the log data hits the replica’s disk, it is encrypted immediately.

To wrap up the technical documentation, we should address the “human element.” Even with the best encryption and file permissions, simple configuration oversights can leave your logs vulnerable.

Here are the most common pitfalls to avoid when hardening MariaDB log security.

To finalize your security documentation, it is important to show users how to monitor the monitors. The MariaDB Audit Plugin is the gold standard for this, as it can track who accessed the server, what queries they ran, and—crucially—who attempted to change log settings.

Audit Policy for Log Integrity

Unlike the General Log, the Audit Plugin allows for fine-grained filtering. This prevents your logs from becoming bloated while ensuring that any “meta-changes” to your security posture are recorded.

Enabling the Plugin

First, the plugin must be installed and enabled. Add this to your configuration:

```
[mariadb]
plugin_load_add = server_audit
server_audit_logging = ON
server_audit_events = CONNECT,QUERY,TABLE
server_audit_file_path = /var/log/mariadb/audit.log
server_audit_file_rotate_size = 100M
server_audit_file_rotations = 5
```

Defining the Security Filter

You don’t want to log every `SELECT` statement, but you do want to log any attempt to disable logging or change security variables. You can filter for specific keywords.

- Filter for Sensitive Operations: You should monitor for any `SET GLOBAL` commands that affect security variables like `general_log`, `slow_query_log`, or `encrypt_binlog`.
- Filter for Privilege Changes: Use the `TABLE` event to track who is modifying the `mysql.user` or `mysql.general_log` tables.

Protecting the Audit Log Itself

The `audit.log` is your “black box” recorder. It requires the highest level of protection:

- Immutable Bit (Linux): On high-security systems, you can use `chattr +a /var/log/mariadb/audit.log` to make the file append-only. Even the `mysql` user won’t be able to delete or modify past entries, only add new ones.
- Remote Syslog: Redirect the audit events to a remote, secure syslog server so that even if the local server is wiped, the audit trail persists.

```
server_audit_output_type = SYSLOG
server_audit_syslog_facility = LOG_LOCAL6
server_audit_syslog_priority = LOG_INFO
```

Summary Table: Who Watches the Watchmen?

Action	Security Goal	Log Source
User Login/Logout	Tracking access windows.	Audit Log (`CONNECT`)
Changing `log_output`	Detecting attempts to hide tracks.	Audit Log (`QUERY`)
Direct Table Edits	Detecting tampering with `mysql.slow_log`.	Audit Log (`TABLE`)
System Errors	Detecting “Log Bomb” or disk space attacks.	Error Log

Verifying Your Security Setup

After restarting MariaDB with your new settings, run these queries to confirm the hardening is active.

Confirm Data-at-Rest Encryption

To verify that your binary logs are actually being encrypted on the disk, check the global status of the encryption threads.

```
SHOW GLOBAL VARIABLES LIKE 'encrypt_binlog';
-- This should return 'ON'

SELECT * FROM INFORMATION_SCHEMA.INNODB_TABLESPACES_ENCRYPTION WHERE NAME='file_binlog';
-- This confirms the encryption plugin is actively managing the binlog files.
```

Confirm Data-in-Transit Encryption (SSL/TLS)

If you are on a replica or a client machine, you can verify that your current connection is secure.

```
SHOW STATUS LIKE 'Ssl_cipher';
-- If this is empty, your connection is NOT encrypted.
-- It should return a cipher suite like 'TLS_AES_256_GCM_SHA384'.

SHOW SESSION STATUS LIKE 'Ssl_version';
-- Ensures you are using a modern protocol (TLSv1.2 or TLSv1.3).
```

Verify Log Destinations

Ensure the server is writing to the correct files (and not to tables, unless intended).

```
SHOW VARIABLES LIKE 'log_output';
-- Should return 'FILE'.

SHOW VARIABLES LIKE '%_log_file';
-- This lists the absolute paths for the Error, General, and Slow logs
-- so you can verify they moved to your secure partition.
```

Test the Audit Plugin

To ensure the “Black Box” is recording, perform a test action that should be caught by your filter (like changing a global variable), then check the log file.

```
-- Run a test change
SET GLOBAL slow_query_log = ON;

-- Then, from the OS terminal, check the audit log:
-- sudo tail /var/log/mariadb/audit.log
```

Common Configuration Pitfalls

Hardcoding Credentials in Configuration Files

When setting up replication or automated log rotation, it is tempting to put the username and password directly into the `[client]` or `[mariadb-dump]` sections of `my.cnf` or `my.ini`.

- This is risky since any user with read access to the config file (often world-readable by default in some environments) can steal the replication or administrative password.
- To close that loophole, use a Secret Store or restricted-access option files. If you must use a file, ensure its permissions are set to `400` or `600` and owned by the `mysql` user.

Leaving the General Log Enabled in Production

The General Query Log records *every* statement sent to the server.

- If an application sends sensitive data (like `INSERT INTO users (password) VALUES ('plain_text_pass')`), that password is now stored in plain text in your log file.
- Only enable the General Log during active debugging. For long-term auditing, use the MariaDB Audit Plugin, which allows you to filter exactly what is logged (for instance, only DDL changes) and mask sensitive information.

Neglecting the Relay Log on Replicas

Don’t just focus all security efforts on the primary server but leave the replicas wide open.

- The Relay Log on the replica contains a mirrored copy of the primary’s binary log. If an attacker gains access to the replica’s file system, they have the same data access as if they had breached the primary.
- Always mirror your security settings (permissions, `encrypt_binlog`, and `log_error` locations) across the entire replication topology.

Overlooking “Insecure Transport” Warnings

If you configure `REQUIRE SSL` for a user, but don’t set `require_secure_transport = ON` globally, the server might still allow unencrypted connections from other users or administrative tools.

- This risks accidental “downgrade” attacks where a tool connects via a non-encrypted port, exposing log-related metadata.
- To close that loophole, explicitly disable non-TLS connections in the `[mariadb]` section of your configuration.

Inadequate “Log Bomb” Protection

Failing to set a maximum size for your error logs or general logs.

- A flood of connection errors (perhaps from a brute-force attack) can cause the Error Log to balloon to hundreds of gigabytes, crashing the server by exhausting disk space.

- Always use `logrotate` (Linux) or a monitoring script (Windows) to alert you when log files exceed a specific percentage of disk capacity.

Configuration Template

Here is a hardened `my.cnf` (Linux) or `my.ini` (Windows) template. This configuration applies the “Defense in Depth” principles, covering encryption, location, and transmission security. Adjust paths and filenames according to your environment.

```
# MariaDB Log Security Hardened Template
# Target: MariaDB 10.6+

[mariadb]
# --- 1. FILE LOCATIONS & AVAILABILITY ---
# Move logs to a dedicated, restricted directory
log_error           = /var/log/mariadb/error.log
general_log_file    = /var/log/mariadb/queries.log
slow_query_log_file = /var/log/mariadb/slow.log

# --- 2. DATA-AT-REST ENCRYPTION ---
# Requires a Key Management Plugin (e.g., file_key_management)
encrypt_binlog          = ON
encrypt_tmp_disk_tables = ON

# --- 3. DATA-IN-TRANSIT SECURITY ---
# Force all connections (including replication) to use TLS/SSL
require_secure_transport = ON
ssl_ca   = /etc/mysql/ssl/ca-cert.pem
ssl_cert = /etc/mysql/ssl/server-cert.pem
ssl_key  = /etc/mysql/ssl/server-key.pem

# --- 4. INTEGRITY & RETENTION ---
# Enable checksums to detect tampering or corruption during transit
binlog_checksum     = CRC32

# Set binary log expiration (e.g., 7 days in seconds)
# 7 days * 24h * 60m * 60s = 604800
binlog_expire_logs_seconds = 604800
max_binlog_size = 100M

# --- 5. OPERATIONAL HYGIENE ---
# Log warnings to the error log (useful for spotting failed login attempts)
log_warnings = 2

# Ensure the slow query log only captures what is necessary
long_query_time = 2.0
log_slow_admin_statements = ON
```

Final Implementation Checklist for your Users

1. Directory Creation: Before restarting MariaDB with these settings, users must create the `/var/log/mariadb/` directory.
2. Permissions: Run `chown -R mysql:mysql /var/log/mariadb` and `chmod 750 /var/log/mariadb`.
3. Key Management: Remember that `encrypt_binlog = ON` requires an active encryption plugin; otherwise, the server will not start.

Log File Security Checklist

Security Category	Action Item	Target Logs	Platform
Access Control	Set permissions to `660` (Files) and `750` (Folders).	All Log Files	Linux / macOS
Access Control	Remove `Everyone` and `Users` groups from ACLs.	All Log Files	Windows

Security Category	Action Item	Target Logs	Platform
Data Integrity	Enable `encrypt_binlog = ON` in `my.cnf` or `my.ini`.	Binary / Relay Logs	All
Availability	Move logs to a dedicated partition/volume.	All Log Files	All
Availability	Configure `logrotate` with `compress` enabled.	Error / General / Slow	Linux
Availability	Set `binlog_expire_logs_seconds` for auto-purge.	Binary Logs	All
Audit Trail	Use `sha256sum` to baseline archived (rotated) logs.	All Archives	All
Replication	Require SSL/TLS for log transmission to replicas.	Binary / Relay Logs	All

Overview of the Binary Log

The binary log contains a record of all changes to the databases, both data and structure, as well as how long each statement took to execute. It consists of a set of binary log files and an index.

This means that statements such as CREATE, ALTER, INSERT, UPDATE and DELETE are logged, whereas statements that have no effect on the data, such as `SELECT` and `SHOW`, are not be logged. If you want to log these, too (at a cost in performance), use the general query log.

If a statement may potentially have an effect, but doesn't, such as an `UPDATE` or `DELETE` that returns no rows, it is still logged (this applies to the default statement-based logging, not to row-based logging - see Binary Log Formats).

The purpose of the binary log is:

- To enable replication, where data is sent from one or more primary servers to one or more replica servers based on the contents of the binary log.
- To assist in backup operations.

A MariaDB server with the binary log enabled runs slightly more slowly.

It is important to protect the binary log, as it may contain sensitive information, including passwords.

Binary logs are stored in a binary, not plain text, format, and so are not readable with a regular editor. However, MariaDB includes mariadb-binlog, a command-line tool for plain-text processing of binary logs.

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are stored in InnoDB tablespaces, rather than binary files. This removes the need of protecting binary logs separately, since they'll "inherit" the same protection as other MariaDB database tables. Also, any other information about log **files** doesn't apply – for example, you cannot specify a storage location for binary logs stored in an InnoDB tablespace.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

Activating the Binary Log

Turning on Binary Logging

To enable binary logging, start the server with the –log-bin option. Alternatively, add this to the configuration file (for instance, `my.cnf`), then restart the server:

```
[client-server]
log_bin
```

Optionally, you can specify a **basename** (with or without a path). If you don't, MariaDB assigns a default basename (for instance, `c525d37c-b2ff-4543-b06f-87012d142d44-bin)`, derived from the UUID or hostname of the computer the server runs on. To the basename, file extensions are added, determining the nature of the log files. See this section for details.

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

On server start, you can set a basename (in the example, with a path) like this:

```
mariadbd --log-bin=/var/log/mariadb/mariadb-logs
```

The following applies:

- If you specify a binary log basename with an extension (for example `.log`), the extension is silently ignored.
- If you don't specify a path with the basename, the server logs into *`datadir`*. (*`Datadir`* is determined by the value of the datadir system variable.)
- If you don't specify a basename, it is strongly recommended to use `--log-basename` or to ensure that replication doesn't stop if the hostname of the computer changes.

Verifying Logging is On

Once `log-bin` or `log_bin` is configured and the server has been restarted, binary logging is enabled. To verify that, issue this statement:

```
SHOW VARIABLES LIKE 'log_bin';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_bin       | ON    |
+---------------+-------+
```

Viewing Log Files

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

To view the log files created by the server, issue this statement:

```
SHOW BINARY LOGS;
+-----------------------------------------------+-----------+
| Log_name                                      | File_size |
+-----------------------------------------------+-----------+
| c525d37c-b2ff-4543-b06f-87012d142d44-bin.000001 |       437 |
| c525d37c-b2ff-4543-b06f-87012d142d44-bin.000002 |       433 |
+-----------------------------------------------+-----------+
```

To see which log file is currently used, issue this statement:

```
SHOW BINLOG STATUS \G
*************************** 1. row ***************************
            File: c525d37c-b2ff-4543-b06f-87012d142d44-bin.000002
        Position: 433
    Binlog_Do_DB:
Binlog_Ignore_DB:
```

To find out where log files are stored, issue this statement:

```
SHOW VARIABLES LIKE 'log_bin_basename' \G
*************************** 1. row ***************************
Variable_name: log_bin_basename
        Value: /opt/homebrew/var/mysql/c525d37c-b2ff-4543-b06f-87012d142d44-bin
```

- `/opt/homebrew/var/mysql/` is the **storage location**.
- `c525d37c-b2ff-4543-b06f-87012d142d44-bin` is the **basename** of the binary log files.

Log File Organization

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

Knowing the **basename**, you can view the log files on the file system, too. Change directory (`cd`) to the **storage location**, and issue this command:

```
ls -1 c525d37c-b2ff-4543-b06f-87012d142d44-bin.*
c525d37c-b2ff-4543-b06f-87012d142d44-bin.000001
c525d37c-b2ff-4543-b06f-87012d142d44-bin.000001.idx
c525d37c-b2ff-4543-b06f-87012d142d44-bin.000002
c525d37c-b2ff-4543-b06f-87012d142d44-bin.000002.idx
c525d37c-b2ff-4543-b06f-87012d142d44-bin.index
```

- **The binary log index** is the file containing an `.index` extension. It is a plain-text file, containing a master list of the binary log files, in order.
  By default, the name of the index file is *basename.index*. This can be overridden with the `--log-bin-index` option.
- **The binary log files** have an extension using consecutive numbers, starting with `.000001`. (The higher the number, the newer the log file is.)
- **The binary log files for GTID binlog indexing** (available from MariaDB 11.4) have an `.idx` extension.

A new binary log file with a new extension (number) is created:

- Every time the server starts.
- When the logs are flushed with a `FLUSH LOGS` statement.
- When the maximum size for a binary log file is reached. (This is determined by max_binlog_size.)

Turning off Logging per Session

Clients with the BINLOG ADMIN privilege can disable and re-enable binary logging for the current session by setting the sql_log_bin variable:

```
SET sql_log_bin = 0; -- turns off logging
SET sql_log_bin = 1; -- turns on logging
```

Reading Log Files

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

Log files, with the exception of the *index* log file, are binary-encoded. To display them in a human-readable format, change directory to the storage location of the log files, and issue this mariadb-binlog command:

```
mariadb-binlog c525d37c-b2ff-4543-b06f-87012d142d44-bin.000001
/*!50530 SET @@SESSION.PSEUDO_SLAVE_MODE=1*/;
/*!40019 SET @@session.max_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
DELIMITER /*!*/;
# at 4
#260205 17:13:09 server id 1  end_log_pos 256 CRC32 0x59977cc7  Start: binlog v 4, server v 12.1.2-
MariaDB-log created 260205 17:13:09 at startup
ROLLBACK/*!*/;
…
```

To store that output permanently (for instance, for later processing), issue a command like this:

```
mariadb-binlog c525d37c-b2ff-4543-b06f-87012d142d44-bin.000001 > binlog.sql
```

Log File Security

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

For instructions how to secure binary log **files**, see Securing MariaDB Logs.

Binary Log Format

There are three formats for the binary log. The default is mixed logging, which is a mix of statement-based and row-based logging. See Binary Log Formats for a detailed discussion.

- FLUSH LOGS - Close and rotate logs
- GTID binlog indexing

This page is licensed: CC BY-SA / Gnu FDL

Binary Log Formats

Supported Binary Log Formats

There are three supported formats for binary log events:

- Statement-Based Logging
- Row-Based Logging
- Mixed Logging (Default)

To see which log format is used, issue this statement:

```
SHOW VARIABLES LIKE 'binlog_format';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| binlog_format | MIXED |
+---------------+-------+
```

Regardless of the format, binary log events are always stored in a binary format, rather than in plain text. MariaDB includes the mariadb-binlog utility that can be used to output binary log events in a human-readable format.

You may want to set the binary log format in the following cases:

- If you execute single statements that update many rows, statement-based logging is more efficient than row-based logging for the replica to download.
- If you execute many statements that don't affect any rows, row-based logging is more efficient than statement-based logging for the replica to download.

- If you execute statements that take a long time to complete, but they ultimately only insert, update, or delete a few rows in the table, row-based logging is more efficient than statement-based logging for the replica to apply.

The default is mixed logging which is replication-safe and requires less storage space than row logging.

The storage engine API also allows storage engines to set or limit the logging format, which helps reduce errors with replicating between primaries and replicas with different storage engines.

Statement-Based Logging

When statement-based logging is enabled, statements are logged to the binary log exactly as they were executed. Temporary tables created on the primary will also be created on the replica.
This mode is only recommended where one needs to keep the binary log as small as possible, the primary and replica have identical data (including using the same storage engines for all tables), and all functions being used are deterministic (repeatable with the same arguments).
Statements and tables using timestamps or auto_increment are safe to use with statement-based logging.

This mode can be enabled by setting the binlog_format system variable to `STATEMENT`.

In certain cases when it would be impossible to execute the statement on the replica, the server will switch to row-based logging for the statement. Some cases of this are:

- When replication has been changed from row-based to statement-based and a statement uses data from a temporary table created during row-based mode. In this case, the temporary tables are not stored on the replica, so row logging is the only alternative.
- ALTER TABLE of a table using a storage engine that stores data remotely, such as the S3 storage engine, to another storage engine.
- One is using SEQUENCEs in the statement or the CREATE TABLE definition.

In certain cases, a statement may not be deterministic, and therefore not safe for replication. If MariaDB determines that an unsafe statement has been executed, it issues a warning like this:

```
[Warning] Unsafe statement written to the binary log using statement format since BINLOG_FORMAT =
STATEMENT. The statement is unsafe because it uses a LIMIT clause. This is unsafe because the set of rows
included cannot be predicted.
```

See Unsafe Statements for Statement-based Replication for more information.

If you need to execute non-deterministic statements, then it is safer to use mixed logging or row-based.

Caveats of Statement-Based Logging

Some tables, like temporary tables created in row mode, do not support statement-based logging (as the data is not in the binary log). Any statement that uses a table that does not support statement logging will use row based logging. This is to ensure that the data on master and the replica are consistent.

Mixed Logging

Mixed logging is the default binary log format.

When mixed logging is enabled, the server uses a combination of statement-based logging and row-based logging. Statement-based logging is used where possible, but when the server determines a statement may not be safe for statement-based logging, it will use row-based logging instead. See Unsafe Statements for Statement-based Replication: Unsafe Statements for a list of unsafe statements.

During one transaction, some statements may be logged with row logging while others are logged with statement-based logging.

This mode can be enabled by setting the binlog_format system variable to `MIXED`.

Row-Based Logging

When row-based logging is enabled, DML statements are **not** logged to the binary log. Instead, each insert, update, or delete performed by the statement for each row is logged to the binary log separately. DDL statements are still logged to the binary log in statement format.

Row-based logging uses more storage than the other log formats but is the safest to use. In practice mixed logging should be as safe.

If you want to be able to see the original query that was logged, you can enable annotated rows events, that is shown with mariadb-binlog, with –binlog-annotate-row-events. This option is on by default.

This mode can be enabled by setting the binlog_format system variable to `ROW`.

> **Warning:**
>
> When the primary server (master) writes a transaction to the binary log that exceeds the `max_allowed_packet` size, replication breaks, issuing an error like this:
>
> ```
> Last_IO_Error: Got fatal error 1236 from master when reading data from binary log: 'log event entry exceeded max_allowed_packet; Increase max_allowed_packet on master; the first event 'mariadb-bin.109824' at 4, the last event read from 'mariadb-bin.109825' at 15113554, the last byte read from 'mariadb-bin.109825' at 15113573.'
> ```
>
> When that happens, the only way to recover is by manually extracting the transaction from the primary server's binary log, and manually applying it to the replica server.
>
> **This issue has been addressed in MariaDB 12.3**, and is described in the following.

Splitting Large Row-Format Replication Events

> **Note:**
>
> This functionality is available from MariaDB 12.3.

The maximum value of the `max_allowed_packet` system variable is 1GB. It can be set to smaller values, but not values bigger than that. For row-based replication, this means that a `ROW`-format replication event bigger than the configured variable value cannot be written to the primary server's binary log. As a consequence, replication breaks. (See the warning above.)

To overcome this limitation (and breakage), a variable named `binlog_row_event_fragment_threshold` can be configured. A valid value for this variable would be equal to or smaller than a connecting replica's configured `slave_max_allowed_packet` value.

Once configured, the primary (master) server behaves differently when encountering large `ROW`-format replication events: When writing a transaction to the binary log that exceeds `binlog_row_event_fragment_threshold`, it splits up the transaction event into smaller chunks. (Those chunks have a type of `Partial_rows_log_event`.) None of those chunks exceed the value of the variable, and so replica servers can read binary log entries without issues.

Caveats of Row-Based Logging

When using row-based logging, some statements work different on the master.

- `DELETE FROM`` *table_name*
  - In row-based mode, the table always uses deletion row-by-row, which can take a long time if the table is big. It can also use a lot of space in the binary log.
  - In `STATEMENT` or `MIXED` mode, truncate is used, if possible (no triggers, no foreign keys etc). This is much faster and uses less space in the binary log.

Compression of the Binary Log

Compression of the binary log can be used with any of the binary log formats, but the best results come from using mixed or row-based logging. You can enable compression by using the `--log_bin_compress` startup option.

Configuring the Binary Log Format

The format for binary log events can be configured by setting the binlog_format system variable. If you have the SUPER privilege, then you can change it dynamically with SET GLOBAL. For example:

```
SET GLOBAL binlog_format='ROW';
```

You can also change it dynamically for just a specific session with SET SESSION. For example:

```
SET SESSION binlog_format='ROW';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
binlog_format=ROW
```

Warning:

Be careful when changing the binary log format when using replication. When you change the binary log format on a server, it only changes the format for that server. Changing the binary log format on a primary has no effect on the replica's binary log format. This can cause replication to give inconsistent results or to fail.

Be careful changing the binary log format dynamically when the server is a replica and parallel replication is enabled. If you change the global value dynamically, then that does not also affect the session values of any currently running threads. This can cause problems with parallel replication, because the worker threads will remain running even after STOP REPLICA is executed. This can be worked around by resetting the slave_parallel_threads system variable. For example:

```
STOP REPLICA;
SET GLOBAL slave_parallel_threads=0;
SET GLOBAL binlog_format='ROW';
SET GLOBAL slave_parallel_threads=4;
START REPLICA;
```

For considerations when replicating temporary tables, see Replicating temporary tables.

Effect of the Binary Log Format on Replicas

A replica applies any events it gets from the primary, regardless of the binary log format. The binlog_format system variable only applies to normal (not replicated) updates.

The binary log format is upwards-compatible. This means replication should always work if the replica is the same or a newer version of MariaDB than the primary.

The mysql Database

Statements that affect the `mysql` database can be logged in a different way to that expected.

If the mysql database is edited directly, logging is performed as expected according to the binlog_format. Statements that directly edit the mysql database include INSERT, UPDATE, DELETE, REPLACE, DO, LOAD DATA INFILE, SELECT, and TRUNCATE TABLE.

If the `mysql` database is edited indirectly, statement logging is used regardless of binlog_format setting. Statements editing the `mysql` database indirectly include GRANT, REVOKE, SET PASSWORD, RENAME USER, ALTER,

DROP and CREATE (except for the situation described below).

`CREATE TABLE ... SELECT` can use a combination of logging formats. The CREATE TABLE portion of the statement is logged using statement-based logging, while the SELECT portion is logged according to the value of `binlog_format`.

Metadata Field Definitions (mariadb-binlog Output)

When using the mariadb-binlog utility to view the binary log, events are presented with a standardized header and specific metadata tags. Understanding these is essential for building replication monitors or audit tools.

Event Header Template: `# at {Position} #YYMMDD HH:MM:SS server id {ID} end_log_pos {Pos} CRC32 {Value} {Event_Type}: ...`

Field	Component	Description
Timestamp	`YYMMDD HH:MM:SS`	The time the event was recorded on the originating server.
Server ID	`Unsigned Integer`	The unique ID of the server where the event originated. This matches the `server_id` used in General and Slow Query logs.
end_log_pos	`Unsigned Integer`	The byte offset (position) of the *next* event in the log file.
Thread ID	`at {ID}`	(Positional) The connection identifier that executed the statement. Matches `Thread ID` in other logs.
GTID	`Domain-ServerID-SeqNo`	Global Transaction ID (e.g., `0-1-100`). Uniquely identifies a transaction across a replication topology.
Xid	`Unsigned Integer`	The internal transaction ID used for 2-Phase Commit (2PC) between storage engines (e.g., InnoDB) and the binary log.
cid	`Unsigned Integer`	Group Commit ID. Transactions with the same `cid` were flushed to disk in the same group.

Impact of Configuration on Log Structure

The structure and verbosity of `ROW` events are significantly altered by several system variables:

- **binlog_row_image**:
  - `FULL`: Logs all columns for both the “before” and “after” images.
  - `MINIMAL`: Logs only the changed columns in the after image and identifying columns (PK/Unique) in the before image. Parsers must handle variable column counts per event.
- **binlog_row_metadata**:
  - `MINIMAL`: Only logs data.
  - `FULL`: Includes column names and data types in the log. This is essential for parsers to decode the log without querying the live database schema.
- **encrypt_binlog**:
  - If `ON`, events are encrypted on disk. For `mariadb-binlog` to display this data, it must directly connect to the server hosting the encrypted binlogs via option `--read-from-remote-server`. `mariadb-binlog` cannot directly decrypt binary logs (see [MDEV-8813|https://jira.mariadb.org/browse/MDEV-8813] for details).

Using and Maintaining the Binary Log

See Overview of the Binary Log for a general overview of what the binary log is, and Activating the Binary Log for how to make sure it's running on your system.

Binary log file security is documented on Securing MariaDB Logs.

For details on using the binary log for replication, see the Replication section.

Purging Log Files

To delete all binary logs on the server, run the RESET MASTER command. To delete all binary logs before a certain datetime, or up to a certain number, use PURGE BINARY LOGS.

If a replica is active but has yet to read from a binary log you attempt to delete, the statement fails with an error. However, if the replica is not connected and has yet to read from a log you delete, the file is deleted, but the replica is unable to continue replicating once it connects again.

Logs can also be removed automatically with the expire_logs_days system variable. This is set to `0` by default (no removal). It can be set to a time, in days, after which a binary log file is automatically removed. Log files are only checked for being older than expire_logs_days upon log rotation, so if your binary log fills up slowly and does not reach max_binlog_size on a daily basis, you may see older logs still being kept. You can also force log rotation, and so expiry deletes, by running FLUSH BINARY LOGS on a regular basis. Always set expire_logs_days higher than any possible replica lag.

From MariaDB 10.6, the binlog_expire_logs_seconds variable allows more precise control over binlog deletion and takes precedence if both are non-zero.

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

If the binary log index file has been removed, or incorrectly manually edited, all of the above forms of purging logs fail. The .index file is a plain text file and can be manually recreated or edited so that it lists only the binary log files that are present, in numeric/age order.

Examples of Log File Purging

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

Safely Purging Binary Log Files While Replicating

To be sure replication is not broken while deleting log files, perform the following steps:

- Get a listing of binary log files on the primary by running SHOW BINARY LOGS.
- Go to each replica server and run SHOW REPLICA STATUS to check which binary log file each replica is currently reading.

- Find the earliest log file still being read by a replica. No log files before this one will be needed.
- If you wish, make a backup of the log files to be deleted
- Purge all log files before (not including) the file identified above.

Limiting the Binlog Size

> **Note:**
>
> This feature is available from MariaDB 11.4.

You can limit the size of the binlog by setting the max_binlog_total_size system variable. If not set to zero, the total size of the binlog is stored in the binlog_disk_use status variable. It's also possible to limit the size of a single binlog file by setting max_binlog_size.

Selectively Logging to the Binary Log

By default, all changes to data or data structure are logged. This behavior can be changed by starting the server with the `--binlog-ignore-db=database_name` or `--binlog-do-db=database_name` options.

`--binlog-ignore-db=database_name` specified a database to ignore for logging purposes, while `--binlog-do-db=database_name` will not log any statements unless they apply to the specified database.

Neither option accepts comma-delimited lists of multiple databases as an option, since a database name can contain a comma. To apply to multiple databases, use the option multiple times.

`--binlog-ignore-db=database_name` behaves differently depending on whether statement-based or row-based logging is used. For statement-based logging, the server will not log any statement where the *default database* is database_name. The default database is set with the USE statement.

Similarly, `--binlog-do-db=database_name` also behaves differently depending on whether statement-based or row-based logging is used.

For statement-based logging, the server will only log statement where the *default database* is database_name. The default database is set with the USE statement.

For row-based logging, the server will log any updates to any tables in the named database/s, irrespective of the current database.

Examples of Selective Logging

Assume the server has started with the option `--binlog-ignore-db=employees`. The following example *is* logged if statement-based logging is used, and *is not* logged with row-based logging.

```
USE customers;
UPDATE employees.details SET bonus=bonus*1.2;
```

This is because statement-based logging examines the default database, in this case, `customers`. Since `customers` is not specified in the ignore list, the statement is logged. If row-based logging is used, the example is not logged, because updates are written to the tables in the `employees` database.

Assume now that the server started with the option `--binlog-do-db=employees`. The following example *is not* logged if statement-based logging is used, and *is* logged with row-based logging.

```
USE customers;
UPDATE employees.details SET bonus=bonus*1.2;
```

This is again because statement-based logging examines the default database, in this case, `customers`. Since `customers` is not specified in the do list, the statement is not logged. If row-based logging is used, the example is

logged as updates are written to the tables in the `employees` database.

Effects of Full Disk Errors on Binary Logging

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

If MariaDB encounters a full disk error while trying to write to a binary log file, then it will keep retrying the write every 60 seconds. Log messages will get written to the error log every 600 seconds. For example:

```
2018-11-27  2:46:46 140278181563136 [Warning] mysqld: Disk is full writing '/var/lib/mariadb-bin.00001'
(Errcode: 28 "No space left on device"). Waiting for someone to free space... (Expect up to 60 secs delay
for server to continue after freeing disk space)
2018-11-27  2:46:46 140278181563136 [Warning] mysqld: Retry in 60 secs. Message reprinted in 600 secs
```

However, if MariaDB encounters a full disk error while trying to open a new binary log file, then it will disable binary logging entirely. A log message like the following will be written to the error log:

```
2018-11-27  3:30:49 140278181563136 [ERROR] Could not open '/var/lib/mariadb-bin.00002 for logging (error
28). Turning logging off for the whole duration of the MySQL server process. To turn it on again: fix the
cause, shutdown the MySQL server and restart it.
2018-11-27  3:30:49 140278181563136 [ERROR] mysqld: Error writing file '(null)' (errno: 9 "Bad file
descriptor")
2018-11-27  3:30:49 140278181563136 [ERROR] mysqld: Error writing file '(null)' (errno: 28 "No space left
on device")
```

Row Binlog Events

A `Row_log_event` is a fundamental structure used in Row-Based Replication (RBR).

When your database is configured to use row-based logging (`binlog_format=ROW`), the binary log doesn't store the actual SQL statements (like `UPDATE users SET status='active'`). Instead, it stores the specific changes made to individual rows. The `Row_log_event` is the container for that data.

Row_log_event

How it Works

When a transaction occurs, MariaDB records the state of the row before and/or after the change. This ensures that the replica database stays perfectly in sync with the primary, regardless of non-deterministic functions (like `NOW()` or `UUID()`) that might cause issues in statement-based replication.

The Three Main Subtypes

While *Row_log_event* is the general category, you usually see it manifested as one of these three specific events in binary logs:

1. `Write_rows` event: Triggered by an `INSERT`. It contains the data for the new rows.
2. `Update_rows` event: Triggered by an `UPDATE`. It contains both the “before” image (to find the row on the replica) and the “after” image (the new data).
3. `Delete_rows` event: Triggered by a `DELETE`. It contains the data of the deleted rows so the replica can identify exactly which ones to remove.

Anatomy of a Row_log_event

Each event contains specific metadata to ensure the data lands in the right place:

- **Table ID:** A numeric identifier mapping the event to a specific table.
- **Columns Present Bitmap:** A sequence of bits identifying which columns are actually included in the event (useful for saving space if only one column in a wide table changed).
- **Row Data:** The actual payload, encoded in a binary format.

Why Does it Matter?

- Consistency: Row-based logging is much more “expensive” in terms of log size than statement-based logging, but it is significantly more reliable for data integrity.
- Point-in-Time Recovery: Tools like `mysqlbinlog` read these events to reconstruct data if a crash occurs.
- Performance: On the primary, it saves the overhead of complex query parsing for the logs, but it can create very large log files if you perform bulk updates (for instance, updating 1 million rows creates 1 million row events).

How to View Them

Log events can be seen by inspecting binary log files with `mariadb-binlog -v` (`-v` stands for verbose). Consider having issued these statements:

```
MariaDB [test]> INSERT INTO mynation VALUES (1001, 'Wonderland', 3, '2026-12-02', 'AL', 'ALC', 5);
Query OK, 1 row affected (0.004 sec)

MariaDB [test]> UPDATE mynation SET name = 'Aliceland' WHERE name = 'Wonderland';
Query OK, 1 row affected (0.006 sec)
Rows matched: 1  Changed: 1  Warnings: 0

MariaDB [test]> DELETE FROM mynation WHERE name = 'Aliceland';
Query OK, 1 row affected (0.006 sec)
```

The binary log now contains a `Write_rows`, an `Update_rows`, and a `Delete_rows` entry:

```
mariadb-binlog -v 6f6d5cb3-8a83-4f4d-a61a-6f3816cfbf93-bin.000002

Partial_rows_log_event

> **Note:**
>
> This log event is available from MariaDB 12.3.

Overview

The `Partial_rows_log_event` was introduced to solve the issue of oversized binary log events. Previously, a single `Rows_log_event` containing a large number of row changes (or very large `BLOB` data) had to be written and transmitted as a single, contiguous block.

A `Partial_rows_log_event` represents a fragment of a larger logical row change. When a standard `Rows_log_event` exceeds the system-defined threshold, MariaDB splits the payload into a sequence of partial events.

> **Note:**
>
> The configuration of splitting log events is described here.

> **Note:**
>
> Note on memory usage: While `Partial_rows_log_event` allows the server to write large updates in fragments to stay within `max_allowed_packet` limits, it does not reduce the memory consumption of the primary server. The transaction still maintains the full row event contiguously in the binary log cache memory before it is fragmented for writing. For reducing memory overhead of large transactions, see InnoDB-based Binary Log.

How Fragmentation Works

Instead of one massive event, the binary log contains a sequence of events structured like this:

1. `Table_map_event`: Identifies the table being modified.
2. `Partial_rows_log_event` (`N` times): Each event is exactly the size of the configured maximum threshold.
3. `Rows_log_event`: The concluding fragment which contains the remaining data and signals the end of the logical group.

Key Characteristics

- Atomic Reassembly: Replicas and log parsers (like `mariadb-binlog`) must buffer all related `Partial_rows_log_event` entries until the final event in the group is received before the rows can be applied.
- Size Determinism: All partial events in a sequence (except the last one) are of a uniform size, defined by the system variable `binlog_row_event_max_size` (or the equivalent threshold setting).
- Order Preservation: Because the binary log is a sequential stream, these fragments always appear contiguously for a single statement within a transaction.

Configuration

Splitting log events is enabled by setting the `binlog_row_event_max_size` variable. See this section for details.

Use Case: Large BLOBs and Bulk Inserts

This feature is particularly beneficial for environments with:

- Limited network buffers: Prevents “packet too large” errors during replication.
- High memory concurrency: Allows the master to stream log data to disk in chunks rather than allocating one massive buffer for a multi-megabyte row change.

Best Practices & Troubleshooting: `Partial_rows_log_event`

Best Practices

- **Align with network MTU:** If you are experiencing “Packet too large” errors or network instability in your replication stream, set `binlog_row_event_max_size` to a value slightly lower than your network’s maximum transmission unit (MTU) or the `max_allowed_packet` setting.
- **Monitor disk I/O:** While fragmentation prevents massive memory allocations, writing many small `Partial_rows_log_event` entries can increase the number of small I/O operations. If you see an I/O bottleneck on the binary log disk, consider increasing the fragment size slightly.
- **Buffer memory on replicas:** Ensure your replicas have sufficient memory. Because the replica must buffer all `Partial_rows_log_event` fragments before applying the final `Rows_log_event`, very large row changes will still consume memory on the “subscriber” side during the reassembly phase.

Troubleshooting & Common Issues

1. Increased Replication Lag

If you notice an increase in replication lag after upgrading to MariaDB 12.3, check the frequency of partial events.

- Cause: The replica is spending more time “assembling” the fragments in memory before the SQL thread can execute them.
- Solution: Increase the threshold size to reduce the number of fragments per row change.

2. `mariadb-binlog` Compatibility

Older versions of `mariadb-binlog` (pre-12.3) will likely fail to parse these events or skip them entirely because they do not recognize the `Partial_rows_log_event` type code.

- Symptom: “Unknown event type” errors or truncated output when reading logs.

- Solution: Always use the `mariadb-binlog` binary that matches or exceeds the version of the MariaDB server generating the logs.

3. Monitoring Fragmentation Frequency

You can monitor how often fragmentation is occurring by checking the binary log headers. If almost every `Rows_log_event` is preceded by a `Partial_rows_log_event`, your threshold is likely set too low for your typical row size (for instance, you have many wide tables or `JSON`/`BLOB` columns).

Observation	Likely Cause	Recommended Action
Frequent small fragments	Threshold too low	Increase `binlog_row_event_max_size`
“Packet too large” errors	Threshold too high	Decrease `binlog_row_event_max_size`
High replica memory usage	Massive row updates	Break up large transactions into smaller batches

Implementation Summary

> **Warning:**
>
> The introduction of `Partial_rows_log_event` does *not* change the transactional nature of MariaDB. The fragments are part of a single unit of work; if the connection is lost mid-fragment, the replica discards the partial buffer and waits for a re-transmission or restart of that event group.

InnoDB-Based Binary Log

> **Note:**
>
> This feature is available from MariaDB 12.3.

Description

Traditionally, MariaDB treated the binary log (binlog) and the InnoDB storage engine as separate components, requiring a complex two-phase commit (2PC) protocol to keep them synchronized. With this new binlog implementation, binlog events are written to InnoDB-managed, page-structured files that are integrated with the InnoDB redo log and crash recovery. This change eliminates the need for an expensive 2PC between the binlog and InnoDB, allowing significant performance improvements and simplified crash recovery behavior.

The binlog files remain separate files on disk (with the `.ibb` extension), but instead of the traditional flat, sequential format they use InnoDB’s page format and durability machinery.

InnoDB-based binary logs entirely replace traditional file-based binary logs. When enabled, the server stops writing traditional binlog files, and the new format becomes the only binary log implementation in use.

Additionally, this feature is limited to the binary log on the server. The relay log on replicas continues to use the traditional implementation and is not affected by the use of InnoDB-based binary logs.

Benefits

The InnoDB-based binlog offers these key performance advantages:

1. **Crash-safe recovery integrated with InnoDB**: The binlog integrates with InnoDB’s crash recovery mechanism, so the binary log and InnoDB always recover to a mutually consistent state without a separate sync of the binlog. You can therefore set `--innodb-flush-log-at-trx-commit=0` or `--innodb-flush-log-at-trx-commit=2` for better performance. As with regular InnoDB tables, those settings trade durability of the most recently committed transactions for speed — but the binlog and InnoDB stay consistent with each other after a crash.

2. **Efficient commits with reduced `fsync` operations**: When using the `--innodb-flush-log-at-trx-commit=1` setting, the system performs only a single coordinated `fsync` per commit, instead of the multiple syncs required by the traditional 2PC.
3. The `sync_binlog` option is no longer required, as binlog files are now crash-safe without separate syncing.

Comparison: Traditional vs. New Binlog

Feature	Traditional Binlog	New InnoDB-Based Binlog
Files on Disk	Numbered files (e.g. `binlog.000001`) plus a `.index` listing file	`.ibb` files (e.g. `binlog-000001.ibb`)
Crash Safety	Requires `sync_binlog=1`	Native — inherited from InnoDB crash recovery
Commit Protocol	Two-Phase Commit (slower)	Integrated (faster)
Positioning	Filename/Offset or GTID	GTID only
File Allocation	Incremental	Pre-allocated (`max_binlog_size`)

When to Use InnoDB-Based Binlogs

Use **InnoDB-based binlogs** when:

- The system requires high transactional throughput with strict durability guarantees.
- Replication topologies are already using GTIDs.
- You are running MariaDB 12.3 or later with GTID replication enabled.

Stay with **traditional binlogs** when:

- The system requires Galera Cluster support.
- Applications depend on filename/offset-based replication positions.
- The environment uses third-party tools that read binlog files directly.

Enabling the InnoDB Binary Log

Configuration

To enable the InnoDB-based binlog, add these options to your MariaDB configuration file:

```
[mariadb]
log_bin
binlog_storage_engine=innodb
```

- The `log_bin` option must be specified without any value.
- The new binlog format is mutually exclusive with the traditional file-based binlog. Old binlog files are ignored after switching to the new format.

For additional configuration options, see Replication and Binary Log System Variables.

Optional Configuration

Custom Binlog Directory

The directory for binary log files can be configured with:

```
[mariadb]
binlog_directory=/path/to/binlog
```

If not specified, the data directory is used by default.

Binary Log Files

Binary log files are written to InnoDB-managed, page-structured files using the .ibb extension. Files follow this naming pattern:

```
binlog-000000.ibb
binlog-000001.ibb
```

Characteristics

- Binlog files are pre-allocated for efficiency. When binlog file N is filled up, event data continues in file N+1, and an empty file N+2 is pre-allocated in the background. Binlog files are therefore always exactly `--max-binlog-size` bytes long; if the server restarts, binlog writing continues at the point reached before shutdown.
- The file size is managed by `max_binlog_size` (by default 1GB).
- Files are page-based (16 KB pages) with a CRC32 checksum at the end of each page.
- There are no binlog index files (`.index`), GTID index files (`.idx`), or GTID state files (`.state`).
- The `--binlog-checksum` option is no longer used. Binlog files are always checksummed with a CRC32 at the end of each page. To checksum data sent over the network between primary and replica, use the `MASTER_SSL` option in `CHANGE MASTER` to enable SSL.

GTID Handling

The new binlog implementation requires GTID-based replication. Instead of GTID index and state files, the binlog periodically writes GTID state records into the binlog itself. When a replica connects (or the server starts up), the binlog is scanned from the last GTID state record to find or recover the correct GTID position.

The interval between state records is controlled by:

```
[mariadb]
innodb-binlog-state-interval=2097152
```

The interval is specified in bytes (default: 2 MB) and must be a power-of-two multiple of the binlog page size (16 KB). This option can be increased to reduce the overhead of state records, or decreased to speed up finding the initial GTID position at replica connect. The overhead is small either way, so normally there is little reason to change the default.

Note: The status variables `binlog_gtid_index_hit` and `binlog_gtid_index_miss` are not used with the new binlog implementation.

For additional configuration options, see Replication and Binary Log System Variables.

Replication

Replication configuration from the primary can be performed as usual. Requirements:

- Replicas must use GTID to connect to the primary (this is the default). The old filename/offset-based replication position is not available when using the new binlog on the primary.
- Replicas should be upgraded to at least MariaDB 12.3 before switching the primary to the new binlog format.
- The primary and replica can independently use either the traditional or new binlog format.

Viewing Binlog Events

Binary log events can be verified from within the server using SQL statements, or from outside the server using the `mariadb-binlog` client utility.

Within the Server

To inspect binary log events directly from a running server instance, use SQL statements:

```
-- View all binlog events
SHOW BINLOG EVENTS;

-- View events from a specific file
SHOW BINLOG EVENTS IN 'binlog-000001.ibb';
```

Note: Event offsets are generally reported as zero; GTID positions should be used instead for navigation.

Using the `mariadb-binlog` Utility

The `mariadb-binlog` utility allows inspection of binary log files either locally or remotely:

```
# Read binary log from a remote server
mariadb-binlog --read-from-remote-server \
               --host=master.example.com --user=repl binlog-000001.ibb

# Read a local binary log file
mariadb-binlog /path/to/binlog-000000.ibb

# Read multiple binary log files (pass all at once, in order)
mariadb-binlog /path/to/binlog-000000.ibb \
               /path/to/binlog-000001.ibb \
               /path/to/binlog-000002.ibb
```

When viewing events across multiple binlog files, all binlog files should be passed to the `mariadb-binlog` program at once in the correct order; this ensures that events that cross file boundaries are included in the output exactly once.

When using `--start-position` and `--stop-position`, it is recommended to use GTID positions. File offsets used in the traditional binlog format are not used in the new binlog and will mostly be reported as zero.

Flushing and Rotating Binary Log Files

To regulate the file size and disk use, binary log files can be manually rotated or purged:

```
-- Flush the current binary log file and create a new one
FLUSH BINARY LOGS;

-- Flush the current binary log and remove a specific GTID domain
FLUSH BINARY LOGS DELETE_DOMAIN_ID=N;

-- Remove binary log files up to a specific file
PURGE BINARY LOGS TO 'binlog-000001.ibb';
```

- `FLUSH BINARY LOGS` pads the current file to the next page boundary, truncates it, and switches to the next file. This can leave a binlog file smaller than `--max-binlog-size` (but always a multiple of the binlog page size).
- `FLUSH BINARY LOGS DELETE_DOMAIN_ID=N` removes an old domain ID from `@@gtid_binlog_pos`. This requires the domain not be in use in any existing binlog files. If the domain ID is already deleted, a warning is issued but the `FLUSH BINARY LOGS` operation still runs.

Note: This behavior differs from the old binlog implementation, where FLUSH is skipped if the domain ID was already deleted.

Automatic Purging

Binlog files can be automatically removed based on age or disk usage, provided they are no longer needed by active replication replicas or for crash recovery:

```
-- Retain binary logs for 7 days (in seconds)
SET GLOBAL binlog_expire_log_seconds = 604800;

-- Retain binary logs for 14 days
SET GLOBAL binlog_expire_log_days = 14;

-- Limit total binary log disk usage to 100 GB
SET GLOBAL max_binlog_total_size = 107374182400;

-- Allow purge in setups where no replicas are configured
slave_connections_needed_for_purge=0
```

Binlog files are only purged when limits are exceeded and files are not required for crash recovery or by active replicas.

Backup using mariadb-backup

Default Behavior

By default, binlog files are included in backups, resolving a long-standing limitation of the traditional binlog.

Key features:

- Binlog files are backed up in a transactionally consistent way, just like other InnoDB data.
- Backups are non-blocking, meaning the server continues running normally. By default, only `RESET MASTER`, `PURGE BINARY LOGS`, and `FLUSH BINARY LOGS` are blocked during the backup. This blocking can be disabled with the `--no-lock` option.
- Restored backups can serve as replicas using `MASTER_DEMOTE_TO_SLAVE=1` in `CHANGE MASTER`.

Setting Up a Replica from Backup

```
# Default backup includes binlog files
mariadb-backup --backup --target-dir=/backup/path

# Exclude binlog files (save space)
mariadb-backup --backup --target-dir=/backup/path --skip-binlog

# Restore on replica
mariadb-backup --prepare --target-dir=/backup/path
mariadb-backup --copy-back --target-dir=/backup/path

# Start MariaDB server
systemctl start mariadb
```

```
# Configure replication
CHANGE MASTER TO
   MASTER_HOST='master.example.com',
   MASTER_USER='repl',
   MASTER_PASSWORD='secret',
   MASTER_USE_GTID=slave_pos,
   MASTER_DEMOTE_TO_SLAVE=1;
START SLAVE;
```

When the `MASTER_DEMOTE_TO_SLAVE=1` option is set, the restored backup can automatically start replicating from the point the backup was taken, using the binlog files included in the backup.

Note that when binlog files are omitted from the backup (`--skip-binlog`), the restored server behaves as if `RESET MASTER` was run at the point of the backup. In that case, the `MASTER_DEMOTE_TO_SLAVE=1` option cannot be used to initialize the replication starting position; instead, the `gtid_slave_pos` variable must be set explicitly from the

information saved by `mariadb-backup`. Any transactions that were prepared but not yet committed at backup time will be rolled back on first startup.

Performance Characteristics

The InnoDB-based binary log eliminates the traditional 2PC protocol between the binary log and the InnoDB storage engine, which results in:

- Reduced commit latency.
- Removal of `sync_binlog` overhead.
- When `--innodb-flush-log-at-trx-commit=1` is set, a single synchronized flush occurs for both table data and binlog.

Commit durability is now controlled solely by –innodb-flush-log-at-trx-commit, which now applies to both binlog files and InnoDB table data.

Flush Policy

- `--innodb-flush-log-at-trx-commit=1`: Performs a single coordinated flush of both table data and binary log, offering greater efficiency compared to the traditional binlog implementation
- `--innodb-flush-log-at-trx-commit=0` or `=2`: Provides higher throughput. As with regular InnoDB tables, these settings trade durability of the most recently committed transactions for speed, but the binlog and InnoDB remain consistent with each other after a crash.

The `sync_binlog` option is effectively ignored when using the InnoDB-based binary log.

GTID State Interval

The `--innodb-binlog-state-interval` configuration option controls how often GTID state records are written to the binary log (default: 2 MB). Lowering this value helps replicas reconnect faster during high traffic. The overhead is small in either direction, so the default is usually appropriate.

Migration and Upgrades

New Installations

For new MariaDB 12.3 and later installations, add the following to your configuration file:

```
[mariadb]
log-bin
binlog-storage-engine=innodb
```

When you enable the InnoDB-based binary log on a new installation, no more migration steps are required.

Migration from Traditional Binlog

When switching an existing server to the new binlog format, the old binlog files will not be available after the switch, as the two formats are mutually exclusive. Choose the method that best suits your environment.

Method 1: Direct Restart Migration (Simple)

This method stops the server, switches the configuration to the new binlog format, and restarts with an empty binlog. It is the simplest migration approach and is applicable for setups where:

- The server is standalone or not part of an active replication topology.
- The old binary log files are no longer needed after the transition.
- Point-in-time recovery from the old binary log files is not required.

To perform a direct restart migration, follow the steps below:

1. Stop the MariaDB server.
2. If `log-bin` is already present in your configuration with a filename (e.g. `log-bin=my-old-binlog`), remove the filename so it reads as just `log-bin` without any value. Then add `binlog-storage-engine=innodb`.
3. Start the server. The new binlog starts empty.
4. Remove the old binlog files from the data directory manually.

Method 2: Replication State Migration (GTID Preservation)

This approach is used to switch a primary server while ensuring connected replicas can continue replicating without full reconfiguration. This method switches the primary to the new binlog format while preserving the GTID state, so that connected replicas can reconnect and continue replicating from where they left off without requiring a full reconfiguration.

This applies to the following types of setups:

- Active replication topologies where replicas must continue replicating after the primary switches format.
- Setups where all replicas have already been upgraded to at least MariaDB 12.3.

Follow the steps below to perform a replication state migration:

1. Stop all writes to the primary.
2. Wait for all replicas to catch up to the primary's current position.
3. Capture the current GTID state by noting down the value of `@@gtid_binlog_state`.
4. Restart the primary with the following configuration:

```
[mariadb]
log-bin
binlog-storage-engine=innodb
```

5. Immediately execute `SET GLOBAL gtid_binlog_state=<old value>` using the value saved in step 3.
6. Allow replicas to reconnect; they will continue from where they left off.

Method 3: Live Migration (Zero Downtime)

This method promotes a replica, already running the new binlog format, to become the new primary, avoiding any downtime on the original primary during the format transition.

It is applicable for the following types of setups:

- Production environments where primary downtime is not acceptable.
- Active replication topologies with at least one available replica that can be promoted to primary.
- Configurations where all replicas have been upgraded to MariaDB 12.3 or higher.

To perform a live migration, follow these steps:

1. Ensure that all replicas are upgraded to at least MariaDB version 12.3 before switching the primary.
2. Choose a replica and restart it with `--binlog-storage-engine=innodb`.
3. Allow the replica to replicate from the old-format primary until it has enough binlog data.
4. Promote this replica to be the new primary.
5. Stop the remaining replicas one at a time, update their configuration to the new binlog format, and restart them.

Using the New Binlog with 3rd-Party Programs

The new binlog uses a different on-disk format than the traditional binlog. The format of individual replication events is the same; however, the files stored on disk are page-based, and each page encapsulates event data to support

splitting events into multiple pieces.

Existing 3rd-party programs that read binlog files directly will need to be modified to support the new format. Until then, such programs require using the traditional binlog format.

The protocol for reading binlog data from a running server (e.g., for a connecting replica) is mostly unchanged. Existing programs that read binlog events from a running server may be able to function unmodified. Similarly, `mariadb-binlog --read-from-remote-server` works as usual.

Key differences for client programs:

- File offsets and file boundaries are no longer meaningful and are no longer reported to connecting clients.
- There are no rotate events at the end of a file specifying the name of the next file.
- There is no new format description event at the start of each new file.
- Effectively, the binlog appears as a single unbroken stream of events to clients.
- The starting position for receiving binlog events must be specified using a GTID position; specifying a filename and file offset is not available.

Binlog File Format Reference

This section describes the on-disk format of binlog files for developers building tools that interact with binlog files directly.

A binlog file consists of a sequence of pages. The page size is currently fixed at 16 KB. The file size is set with `--max-binlog-size`. Each page has a CRC32 in the last 4 bytes; all remaining bytes are used for data.

Numbers are stored in little-endian format. Some numbers are stored as compressed integers consisting of 1–9 bytes. The lower 3 bits determine the number of bytes used (one more than the value in the lower 3 bits, except that a value of 7 means 9 bytes are used). The stored value is the little-endian value of the used bytes, right-shifted by 3.

File Header Page

The first page in each binlog file is a file header page:

Offset	Size	Description
0	4	Magic value `0x010dfefe` identifying the file as a binlog file
4	4	Log-2 of the page size (currently fixed at 14 for 16 KB)
8	4	Major file version (currently 1). A new major version is not readable by older server versions
12	4	Minor file version (currently 0). New minor versions are backwards-compatible
16	8	File number (same as the number in the `binlog-NNNNNN.ibb` filename), for consistency check
24	8	Size of the file, in pages
32	8	InnoDB LSN corresponding to the start of the file, used for crash recovery
40	8	Value of `--innodb-binlog-state-interval` used in the file
48	8	File number of the earliest file this file may reference (used to prevent purging files still needed for large split events)
56	8	File number of the earliest file containing pending XA transactions that may still be active
64	448	Unused
512	4	Extra CRC32 (the header can be read as a 512-byte page to determine the real page size)

Data Pages and Chunks

Remaining pages are data pages. Data is structured as a sequence of records; each record consists of one or more chunks. A page contains one or more chunks; a record can span multiple pages, but a chunk always fits within one

page. Chunks are a minimum of 4 bytes; any remaining 1–3 bytes of a page are filled with `0xff`. Unused bytes are set to `0x00`.

A chunk consists of a type byte, two length bytes (little-endian, counting only data bytes), and the data bytes.

The high two bits of the type byte collect chunks into records:

- Bit 7 is clear for the first chunk in a record, and set for all following chunks.
- Bit 6 is set for the last chunk in a record, and clear for all prior chunks.

Chunk Types

Type	Description
0	Not a real type. `0x00` is an unused byte and denotes end-of-data in the current binlog file.
1	**Commit record** — contains binlog event data. Starts with a compressed integer for the count of out-of-band (oob) records referenced; if non-zero, four more compressed integers give the file number and offset of the first and last oob reference. A second similar group follows for mixed transactional/non-transactional event groups. The remainder is payload data.
2	**GTID state record** — written every `--innodb-binlog-state-interval` bytes. Contains: the number of GTIDs in the state (compressed int); one more than the earliest file number with possibly active XA transactions (or 0 for none); then N×3 compressed integers, each representing one GTID in the state.
3	**Out-of-band (oob) data record** — used to split large event groups into smaller pieces organized as a forest of perfect binary trees. Starts with 5 compressed integers: node index; file number and offset of the left child oob node; file number and offset of the right child oob node. The remainder is payload event data.
4	**Filler record** — pads out the last page of a binlog file truncated by `FLUSH BINARY LOGS`.
5	**XA PREPARE record** — for consistent crash recovery of user XA transactions. Starts with 1 byte counting the number of participating storage engines, then the XID (4-byte formatID; 1-byte gtrid length; 1-byte bqual length; XID name characters). Followed by 5 compressed integers: oob node count; file number and offset of first and last oob node.
6	**XA complete record** — for recovery of internal 2PC and user XA. First byte is type: `0` = commit, `1` = XA rollback. Followed by 6–134 bytes of XID in the same format as the XA PREPARE record.

Limitations and Unsupported Features

The following list of features are not supported when using the InnoDB-based binary log implementation:

Replication Positioning

Old-style filename/offset replication positions are not supported. Replication must use GTID-based replication (the default). The following are not available with the new binlog:

- `MASTER_POS_WAIT()` — use `MASTER_GTID_WAIT()` instead.
- `BINLOG_GTID_POS()`
- `RESET MASTER TO` (plain `RESET MASTER` remains available)

Semi-Synchronous Replication

Semi-synchronous replication is not supported in the initial implementation. The `AFTER_SYNC` option cannot be supported because the traditional 2PC no longer exists. The `--init-rpl-role` option is also not supported.

Savepoints Inside Triggers

Using savepoints inside triggers is not supported, due to bugs and inconsistencies (see MDEV-38465). Executing a `SAVEPOINT` or `ROLLBACK TO SAVEPOINT` statement inside a trigger will consistently error and roll back the entire statement.

Galera Cluster

The InnoDB-based binary log cannot be used with MariaDB Galera Cluster. Users running Galera must continue using the traditional binlog format.

XA Transaction Replication

External XA transactions are fully supported and crash-safe on the primary. The new binlog stores `XA PREPARE` and `XA COMMIT` / `XA ROLLBACK` records internally (see chunk types 5 and 6 in the Binlog File Format Reference), and the server will always recover prepared transactions to a state consistent with the binlog after a crash.

However, replicating `XA PREPARE` to a replica is not supported. This means that if the primary has transactions in a prepared-but-not-yet-committed state at the time of a failover, it is not possible to promote the replica and rescue those prepared transactions.

Binary Log Encryption

Binary log encryption (`--encrypt-binlog`) is not supported with the InnoDB-based binary log. Use full-disk encryption at the operating-system level instead, and/or SSL for the replica's connection to the primary (use the `MASTER_SSL` option in `CHANGE MASTER`).

Heuristic Recovery

The `--tc-heuristic-recover` option is not supported. Any pending prepared transactions will always be rolled back or committed to be consistent with the binlog. If the binary log is empty (i.e., deleted manually), pending transactions will be rolled back.

SHOW BINLOG EVENTS FROM Behavior

`SHOW BINLOG EVENTS FROM` does not return an error if the specified position falls in the middle of an event group. Instead, it starts from the first GTID event following the position, or returns empty if the position is past the end of the log.

`sync_binlog` Option

The `sync_binlog` option is no longer needed and is effectively ignored. Durability of commits is now controlled solely by `--innodb-flush-log-at-trx-commit` , which applies to both binlog files and InnoDB table data.

Multiple Storage Engines

In the initial version, only InnoDB is available as a storage engine for the binlog (`--binlog-storage-engine=innodb`).

Compressing Events to Reduce Size of the Binary Log

Selected events in the binary log can be optionally compressed, to save space in the binary log on disk (or, from MariaDB 12.3, in InnoDB tablespaces) and in network transfers.

Events that can be compressed are those that can be of significant size:

- Query events (for DDL[22] and DML[23] in statement-based replication), and
- Row events (for DML[24] in row-based replication).

Compression is fully transparent. Events are compressed on the primary before being written to the binary log, and are uncompressed by the I/O thread on the replica before being written to the relay log. The mariadb-binlog command will likewise uncompress events for its output.

The `zlib` compression algorithm is used to compress events.

Compression has the greatest impact when events are of a non-negligible size, as each event is compressed individually – like batch `INSERT` statements that add many rows or large values, or row-based events that affect a number of rows in one query.

The log_bin_compress option is used to enable compression of events. Only events with data (query text or row data) above a certain size are compressed; the limit is set with the log_bin_compress_min_len option.

Flashback

Flashback is a feature that allows instances, databases or tables to be rolled back to an old snapshot.

Flashback is supported only for DML statements (INSERT, DELETE, UPDATE). (An upcoming version of MariaDB will add support for flashback for DDL statements (DROP, TRUNCATE, ALTER, etc.) by copying or moving the current table to a reserved and hidden database, and then copying or moving back when using flashback. See MDEV-10571.)

Flashback is achieved in MariaDB Server using existing support for full image format binary logs (binlog_row_image=FULL), so it supports all engines.

The real work of Flashback is done by mariadb-binlog with `--flashback`. This causes events to be translated: `INSERT` to `DELETE`, `DELETE` to `INSERT`, and for `UPDATE` statements, the before and after images are swapped.

> **Note:**
>
> When executing `mariadb-binlog` with `--flashback`, the Flashback events are stored in memory. Make sure your server has enough memory for this feature.

Arguments

- mariadb-binlog has the `--flashback` or `-B` option that makes it work in flashback mode.
- mariadbd has the option –flashback that enables the binary log and sets `binlog_format=ROW`. It is not mandatory to use this option if you have already enabled those options directly.

Do not use the `-v` or `-vv` options, as they add verbose information to the binary log which can cause problems when importing. See MDEV-12066 and MDEV-12067.

Example

With a *`mytable`* table in a *`test`* database, you can compare the output with `--flashback` and without:

```
mariadb-binlog /var/lib/mysql/mysql-bin.000001 -vv -d test -T mytable \
    --start-datetime="2013-03-27 14:54:00" > review.sql
```

```
mariadb-binlog /var/lib/mysql/mysql-bin.000001 -vv -d test -T mytable \
    --start-datetime="2013-03-27 14:54:00" --flashback > flashback.sql
```

If you know the exact position, `--start-position` can be used instead of `--start-datetime`.

Then, by importing the output file (`mariadb < flashback.sql`), you can flash your database/table back to the specified time or position.

Common Use Case

A common use case for Flashback is the following scenario:

- You have one primary and two replicas, one started with `--flashback` (i.e., with binary logging enabled, using binlog_format=ROW, and binlog_row_image=FULL).
- Something goes wrong on the primary (like a wrong update or delete) and you would like to revert to a state of the database (or just a table) at a certain point in time.
- Remove the flashback-enabled replica from replication.
- Invoke mariadb-binlog to find the exact log position of the first offending operation after the state you want to revert to.
- Run `mariadb-binlog --flashback --start-position=xyz | mariadb` to pipe the output of `mariadb-binlog` directly to the `mariadb` client, or save the output to a file and then direct the file to the command-line client.

Group Commit for the Binary Log

Overview

The server supports group commit. This is an important optimization that helps MariaDB reduce the number of expensive disk operations that are performed.

Durability

In ACID terminology, the “D” stands for durability. In order to ensure durability with group commit, innodb_flush_log_at_trx_commit=1 and/or sync_binlog=1 should be set. These settings are needed to ensure that if the server crashes, any transaction that was committed prior to the time of crash is still present in the database after crash recovery.

Durable InnoDB Data and Binary Logs

Setting both innodb_flush_log_at_trx_commit=1 and sync_binlog=1 provides the most durability and the best guarantee of replication consistency after a crash.

Non-Durable InnoDB Data

If sync_binlog=1 is set, but innodb_flush_log_at_trx_commit is not set to `1` or `3`, it is possible after a crash to end up in a state where a transaction present in a server binary log is missing from the server’s InnoDB redo log. If the server is a replication primary, this means that the server can become inconsistent with its replicas, since the replicas may have replicated transactions from the primary’s binary log that are no longer present in the primary’s local InnoDB data.

Non-Durable Binary Logs

If innodb_flush_log_at_trx_commit is set to `1` or `3`, but sync_binlog=1 is not set, it is possible after a crash to end up in a state where a transaction present in a server’s InnoDB redo log is missing from the server’s binary log. If the server is a replication primary, this also means that the server can become inconsistent with its replicas, since the server’s replicas would not be able to replicate the missing transactions from the server’s binary log.

Non-Durable InnoDB Data and Binary Logs

Setting innodb_flush_log_at_trx_commit=1 when sync_binlog=1 is not set can also cause the transaction to be missing from the server's InnoDB redo log due to some optimizations added in those versions. In that case, it is recommended to always set sync_binlog=1. If you can't do that, it is recommended to set innodb_flush_log_at_trx_commit to `3`, rather than `1`. See Non-durable Binary Log Settings for more information.

Amortizing Disk Flush Costs

> **Note:**
>
> From MariaDB 12.3, InnoDB-based binary logs can be used. (This is configurable, and not the default.)
>
> If configured, binary logs are written to InnoDB-managed, page-structured files (with the `.ibb` extension) that are integrated with InnoDB's redo log and crash recovery, rather than the traditional flat binary log files. This removes the need to protect the binary log separately, since it "inherits" the same crash safety as other InnoDB data, and it removes the need for expensive two-phase commit between InnoDB transactions and the binary log. Some options that apply to traditional binary log files behave differently or no longer apply – for example, `sync_binlog` is effectively ignored.
>
> InnoDB-based binary logs are enabled by setting `binlog_storage_engine=innodb` in the server configuration. See InnoDB-Based Binary Log for more information.

After every transaction COMMIT, the server normally has to persist any changes the transaction made to the InnoDB redo log and the binary log to non-volatile storage. This helps ensure that the data changes made by the transaction are durable. Disk flushing is a time-consuming operation, and can easily impose limits on throughput in terms of the number of transactions-per-second (TPS) which can be committed.

The idea with group commit is to amortize the costs of each flush to disk over multiple commits from multiple parallel transactions. For example, if there are 10 transactions trying to commit in parallel, then we can force all of them to be flushed disk at once with a single system call, rather than do one system call for each commit. This can greatly reduce the need for flush operations, and can consequently greatly improve the throughput of transactions-per-second (TPS).

However, to see the positive effects of group commit, the workload must have sufficient parallelism. A good rule of thumb is that at least three parallel transactions are needed for group commit to be effective. For example, while the first transaction is waiting for its flush operation to complete, the other two transactions will queue up waiting for their turn to flush their changes to disk. When the first transaction is done, a single system call can be used to flush the two queued-up transactions, saving in this case one of the three system calls.

In addition to sufficient parallelism, it is also necessary to have enough transactions per second wanting to commit that the flush operations are a bottleneck. If no such bottleneck exists (i.e., transactions never or rarely need to wait for the flush of another to complete), then group commit will provide little to no improvement.

Changing Group Commit Frequency

The frequency of group commits can be changed by configuring the binlog_commit_wait_usec and binlog_commit_wait_count system variables.

Measuring Group Commit Ratio

Two status variables are available for checking how effective group commit is at reducing flush overhead. These are the Binlog_commits and Binlog_group_commits status variables. We can obtain those values with the following query:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
```

Binlog_commits is the total number of transactions committed to the binary log.

Binlog_group_commits is the total number of groups committed to the binary log. As explained in the previous sections of this page, a group commit is when a group of transactions is flushed to the binary log together by sharing a single flush system call. When sync_binlog=1 is set, this is also the total number of flush system calls executed in the process of flushing commits to the binary log.

Thus, the extent to which group commit is effective at reducing the number of flush system calls on the binary log can be determined by the ratio between these two status variables. Binlog_commits are always equal to or greater than Binlog_group_commits. The greater the difference is between these status variables, the more effective group commit was at reducing flush overhead.

To calculate the group commit ratio, we need the values of these status variables from two snapshots. With those, we can calculate the ratio with the following formula:

`transactions/group commit` = (`Binlog_commits` (*snapshot2*) - `Binlog_commits` (*snapshot1*))/(`Binlog_group_commits` (*snapshot2*) - `Binlog_group_commits` (*snapshot1*))

For example, if we had the following first snapshot:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| Binlog_commits       | 120   |
| Binlog_group_commits | 120   |
+----------------------+-------+
2 rows in set (0.00 sec)
```

And the following second snapshot:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| Binlog_commits       | 220   |
| Binlog_group_commits | 145   |
+----------------------+-------+
2 rows in set (0.00 sec)
```

Then we would have:

`transactions/group commit` = (220 - 120) / (145 - 120) = 100 / 25 = 4 `transactions/group commit`

If your group commit ratio is too close to `1`, it may help to change your group commit frequency.

Use of Group Commit with Parallel Replication

Group commit is also used to enable conservative mode of in-order parallel replication.

Effects of Group Commit on InnoDB Performance

When both innodb_flush_log_at_trx_commit=1 (the default) is set and the binary log is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3). See Binary Log Group Commit and InnoDB Flushing Performance for more information.

Status Variables

Binlog_commits is the total number of transactions committed to the binary log.

Binlog_group_commits is the total number of groups committed to the binary log.

Binlog_group_commit_trigger_count is the total number of group commits triggered because of the number of binary log commits in the group reached the limit set by the system variable binlog_commit_wait_count.

Binlog_group_commit_trigger_lock_wait is the total number of group commits triggered because a binary log commit was being delayed because of a lock wait where the lock was held by a prior binary log commit. When this happens the later binary log commit is placed in the next group commit.

Binlog_group_commit_trigger_timeout is the total number of group commits triggered because of the time since the first binary log commit reached the limit set by the system variable binlog_commit_wait_usec.

Issue this statement to query these variables:

```
SHOW GLOBAL STATUS LIKE 'Binlog_%commit%';
```

Relay Log

The relay log is a set of log files created by a replica during replication.

It's the same format as the binary log, containing a record of events that affect the data or structure; thus, mariadb-binlog can be used to display its contents. It consists of a set of relay log files and an index file containing a list of all relay log files.

Events are read from the primary's binary log and written to the replica's relay log. They are then applied on the replica. Old relay log files are automatically removed once they are no longer needed.

Creating Relay Log Files

New relay log files are created by the replica under the following circumstances:

- When the IO thread starts.
- When the logs are flushed, with FLUSH LOGS or mariadb-admin flush-logs.
- When the maximum size has been reached, determined by the max_relay_log_size system variable.

Relay Log Names

By default, the relay log will be given a name `host_name-relay-bin.nnnnnn`, with `host_name` referring to the server's host name, and #nnnnnn `the sequence number.`

This causes problems if the replica's host name changes, returning this error:

```
Failed to open the relay log and Could not find target log during relay log initialization
```

To prevent this, you can specify the relay log file name by setting the relay_log and relay_log_index system variables.

If you need to overcome this issue while replication is already underway, you can stop the replica, prepend the old relay log index file to the new relay log index file, and restart the replica.

For example:

```
shell> cat NEW_relay_log_name.index >> OLD_relay_log_name.index
shell> mv OLD_relay_log_name.index NEW_relay_log_name.index
```

Viewing Relay Logs

The SHOW RELAYLOG EVENTS shows events in the relay log, and, since relay log files are the same format as binary log files, they can be read with the mariadb-binlog utility.

Removing Old Relay Logs

Old relay logs are automatically removed once all events have been implemented on the replica, and the relay log file is no longer needed. This behavior can be changed by adjusting the relay_log_purge system variable from its default of `1` to `0`, in which case the relay logs will be left on the server.

Relay logs are also removed by the CHANGE MASTER statement unless a relay log option is used.

One can also flush the logs with the FLUSH RELAY LOGS statements.

If the relay logs are taking up too much space on the replica, the relay_log_space_limit system variable can be set to limit the size. The IO thread stops until the SQL thread has cleared the backlog. By default there is no limit.

Selectively Skipping Replication of Binlog Events

> **Note:**
>
> The terms *master* and *slave* have historically been used in replication, and MariaDB has begun the process of adding *primary* and *replica* synonyms. The old terms will continue to be used to maintain backward compatibility - see MDEV-18777 to follow progress on this effort.

Normally, all changes that are logged as events in the binary log are also replicated to all replicas (though still subject to filtering by replicate-do-db, replicate-ignore-db, and similar options). However, sometimes it may be desirable to have certain events logged in the binlog, but not replicated to all or to some replicas, where the distinction between events that should be replicated or not is under the control of the application making the changes.

This can be useful if an application does some replication external to the server outside of the built-in replication, or if it has data that for some reason should not be replicated.

This is possible with the following system variables.

Primary Session Variable: skip_replication

When the skip_replication variable is set to true, changes are logged into the binary log with the flag `@@skip_replication` set. Such events are not replicated by replicas that run with `--replicate-events-marked-for-skip` set differently from the default (which is `REPLICATE`).

Variable Name	skip_replication
Scope	Session only
Access Type	Dynamic
Data Type	bool
Default Value	`OFF`

The `skip_replication` option only has effect if binary logging is enabled and sql_log_bin is true.

Attempting to change `@@skip_replication` in the middle of a transaction fails. This is to avoid getting half of a transaction replicated while the other half is not replicated. Be sure to end any current transaction with `COMMIT` / `ROLLBACK` before changing the variable.

Replica Option: –replicate-events-marked-for-skip

The replicate_events_marked_for_skip option tells the replica whether to replicate events that are marked with the `@@skip_replication` flag. Default is `REPLICATE`, to ensure that all changes are replicated to the replica. If set to `FILTER_ON_SLAVE`, events so marked will be skipped on the replica and not replicated. If set to `FILTER_ON_MASTER`, the filtering is done on the primary, saving network bandwidth as the events are not received by the replica at all.

Variable Name	replicate_events_marked_for_skip
Scope	Global
Access Type	Dynamic
Data Type	enum: `REPLICATE` | `FILTER_ON_SLAVE` | `FILTER_ON_MASTER`
Default Value	`REPLICATE`

> **Note:**
>
> `replicate_events_marked_for_skip` is a dynamic variable (it can be changed without restarting the server). However, the replica threads must be stopped when it is changed, otherwise an error is thrown.

When events are filtered due to `@@skip_replication`, the filtering happens on the primary side; in other words, the event is never sent to the replica. If many events are filtered like this, a replica can sit a long time without receiving any events from the primary. This is not a problem in itself, but must be kept in mind when inquiring on the replica about events that are filtered. For example, `START SLAVE UNTIL <some position>` stops when the first event that is **not** filtered is encountered at the given position or beyond. If the event at the given position is filtered, then the replica thread only stops when the next non-filtered event is encountered. In effect, if an event is filtered, to the replica it appears that it was never written to the binlog on the primary.

Note that when events are filtered for a replica, the data in the database is different on the replica and on the primary. It is the responsibility of the application to replicate the data outside of the built-in replication or otherwise ensure consistency of operation. If this is not done, it is possible for replication to encounter, for example, UNIQUE constraint violations or other problems which will cause replication to stop and require manual intervention to fix.

The session variable `@@skip_replication` can be changed without requiring special privileges. This makes it possible for normal applications to control it without requiring `SUPER` privileges. But it must be kept in mind when using replicas with `--replicate-events-marked-for-skip` set different from `REPLICATE`, as it allows any connection to do changes that are not replicated.

skip_replication and sql_log_bin

@@sql_log_bin and `@@skip_replication` are somewhat related, as they can both be used to prevent a change on the primary from being replicated to the replica. The difference is that with `@@skip_replication`, changes are still written into the binlog, and replication of the events is only skipped on replicas that explicitly are configured to do so, with `--replicate-events-marked-for-skip` different from `REPLICATE`. With `@@sql_log_bin`, events are not logged into the binlog, and so are not replicated by any replica.

skip_replication and the Binlog

When events in the binlog are marked with the `@@skip_replication` flag, the flag will be preserved if the events are dumped by the mariadb-binlog program and re-applied against a server with the mariadb client program. Similarly, the BINLOG statement will preserve the flag from the event being replayed. And a replica which runs

with `--log-slave-updates` and does not filter events (`--replicate-events-marked-for-skip=REPLICATE`) also preserves the flag in the events logged into the binlog on the replica.

Error Log

The error log contains a record of critical errors that occurred during the server's operation, table corruption, start and stop information.

SQL errors can also be logged in a separate file using the SQL_ERROR_LOG plugin.

Configuring the Error Log Output Destination

MariaDB always writes its error log, but the destination is configurable.

Writing the Error Log to a File

To configure the error log to be written to a file, you can set the log_error system variable. You can configure a specific file name. However, if a specific file name is not configured, the log will be written to the `${hostname}.err` file in the datadir directory by default.

The log_error system variable can be set in a server option group in an option file prior to starting up the server. For example, to write the error log to the default `${hostname}.err` file, you could configure the following:

```
[mariadb]
...
log_error
```

If you configure a specific file name as the log_error system variable, and if it is not an absolute path, then it will be relative to the datadir directory. For example, if you configured the following, then the error log would be written to `mariadb.err` in the datadir directory:

```
[mariadb]
...
log_error=mariadb.err
```

If it is a relative path, then the log_error is relative to the datadir directory.

However, the log_error system variable can also be an absolute path:

```
[mariadb]
...
log_error=/var/log/mysql/mariadb.err
```

Another way to configure the error log file name is to set the log-basename option, which configures MariaDB to use a common prefix for all log files (e.g. general query log, slow query log, error log, binary logs, etc.). The error log file name will be built by adding a `.err` extension to this prefix. For example, if you configured the following, then the error log would still be written to `mariadb.err` in the datadir directory:

```
[mariadb]
...
log-basename=mariadb
log_error
```

The log-basename cannot be an absolute path. The log file name is relative to the datadir directory.

Writing the Error Log to Stderr on Unix

On Unix, if the log_error system variable is not set, errors are written to `stderr`, which usually means that the log messages are output to the terminal that started `mariadbd`.

If the log_error system variable was set in an option file or on the command-line, it can still be unset by specifying `--skip-log-error`.

Writing the Error Log to Syslog on Unix

On Unix, the error log can also be redirected to the syslog. How this is done depends on how you start MariaDB.

Syslog with mariadbd-safe

If you start MariaDB with mariadbd-safe, the error log can be redirected to the syslog. See mariadbd-safe: Configuring MariaDB to Write the Error Log to Syslog for more information.

Syslog with Systemd

If you start MariaDB with systemd, the error log can also be redirected to the syslog. See Systemd: Configuring MariaDB to Write the Error Log to Syslog for more information.

systemd also has its own logging system called the `journal`, and some errors may get logged there instead. See Systemd:Systemd Journal for more information.

Writing the Error Log to Console on Windows

On Windows, if the console option is specified, and if the log_error system variable is not used, errors are written to the console. If both options are specified, the last option takes precedence.

Writing the Error Log to the Windows Event Viewer

On Windows, error log messages are also written to the Windows Event Viewer. You can find MariaDB's error log messages by browsing **Windows Logs**, then selecting **Application** or **Application Log**, depending on the Windows version.

You can find MariaDB's error log messages by searching for the **Source** `MariaDB` (prior to MariaDB 10.4, this was `MySQL`).

Finding the Error Log

To find where the error log is stored, one can find the options used for the error log with:

```
mariadbd --print-defaults
```

or (from MariaDB 10.11)

```
my_print_defaults --mariadbd | grep log-error
```

or

```
my_print_defaults --mysqld | grep log-error
```

If the above don't help, check also if your system is set to write to syslog, in which case you need to use journalctl to access it.

Configuring the Error Log Verbosity

The default value of the log_warnings system variable is `2`.

The log_warnings system variable can be used to configure the verbosity of the error log. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_warnings=3;
```

It can also be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_warnings=3
```

Some of the warnings included in each verbosity level are described below.

The log_warnings system variable only has an effect on some log messages. Some log messages are **always** written to the error log, regardless of the error log verbosity. For example, most warnings from the InnoDB storage engine are not affected by log_warnings. For a complete list of log messages affected by log_warnings, see the description of the log_warnings system variable.

Verbosity Level 0

If log_warnings is `0`, many optional warnings will not be logged. However, this does not prevent all warnings from being logged, because there are certain core warnings that will always be written to the error log. For example:

- If InnoDB strict mode is disabled, and if DDL is performed on a table that triggers a "Row size too large" error, InnoDB logs a warning:

```
[Warning] InnoDB: Cannot add field col25 in table db1.tab because after
  adding it, the row size is 8477 which is greater than maximum allowed
  size (8126) for a record on index leaf page.
```

However, if InnoDB strict mode is enabled, the same message will be logged as an error.

Verbosity Level 1

Default until MariaDB 10.2.3. If log_warnings is `1`, many types of warnings are logged. Some useful warnings are:

- Replication-related messages:

```
[Warning] A server restart has recreated the memory table `db`.`tbl`; a TRUNCATE query is written to the
binary log at GTID 0-1-2. As this server is a read-only slave, this event may diverge replication in
domain 0.
[Note] Error reading relay log event: slave SQL thread was killed
[Note] Slave SQL thread exiting, replication stopped in log
  'dbserver-2-bin.000033'   at position 181420;
  GTID position '0-263316466-368886'
[Note] Slave I/O thread exiting, read up to log
  'dbserver-2-bin.000034', position 642;
  GTID position 0-263316466-368887
```

- Messages related to DNS lookup failures:

```
[Warning] IP address '192.168.1.193'
  could not be resolved: Name or service not known
```

- Messages related to the event scheduler:

```
[Note] Event Scheduler: Loaded 0 events
```

- Messages related to unsafe statements for statement-based replication:

```
[Warning] Unsafe statement written to the binary log using statement format since
  BINLOG_FORMAT = STATEMENT. The statement is unsafe because
  it uses a LIMIT clause. This
  is unsafe because the set of rows included cannot be predicted.
```

Frequent warnings about unsafe statements for statement-based replication can cause the error log to grow very large. MariaDB will automatically detect frequent duplicate warnings about unsafe statements for statement-based replication. After 10 identical warnings are detected, MariaDB will prevent that same warning from being written to the error log again for the next 5 minutes.

Verbosity Level 2

Default from MariaDB 10.2.4. If log_warnings is `2`, a couple other different kinds of warnings are printed. For example:

- Messages related to access denied errors:

```
[Warning] Access denied for user 'root'@'localhost' (using password: YES)
```

- Messages related to connections that are aborted due to errors or timeouts:

```
[Warning] Aborted connection 35 to db: 'unconnected' user:
  'user1@host1' host: '192.168.1.40' (Got an error writing communication packets)
[Warning] Aborted connection 36 to db: 'unconnected' user:
  'user1@host2' host: '192.168.1.230' (Got an error writing communication packets)
[Warning] Aborted connection 38 to db: 'db1' user:
  'user2' host: '192.168.1.60' (Unknown error)
[Warning] Aborted connection 51 to db: 'db1' user:
  'user2' host: '192.168.1.50' (Got an error reading communication packets)
[Warning] Aborted connection 52 to db: 'db1' user:
  'user3' host: '192.168.1.53' (Got timeout reading communication packets)
```

- Messages related to table handler errors:

```
[Warning] Can't find record in 'tab1'.
[Warning] Can't write; duplicate key in table 'tab1'.
[Warning] Lock wait timeout exceeded; try restarting transaction.
[Warning] The number of locks exceeds the lock table size.
[Warning] Update locks cannot be acquired during a READ UNCOMMITTED transaction.
```

- Messages related to the files used to persist replication state:
  - Either the default `master.info` file or the file that is configured by the master_info_file option.
  - Either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

```
[Note] Reading Master_info: '/mariadb/data/master.info'
  Relay_info:'/mariadb/data/relay-log.info'
[Note] Initialized Master_info from '/mariadb/data/master.info'
[Note] Reading of all Master_info entries succeeded
[Note] Deleted Master_info file '/mariadb/data/master.info'.
[Note] Deleted Master_info file '/mariadb/data/relay-log.info'.
```

- Messages about a master's binary log dump thread:

```
[Note] Start binlog_dump to slave_server(263316466), pos(, 4)
```

Verbosity Level 3

If log_warnings is `3`, a couple other different kinds of warnings are printed. For example:

- Messages related to old-style language options:

```
[Warning] An old style --language value with language specific
  part detected: /usr/local/mysql/data/
[Warning] Use --lc-messages-dir without language specific part instead.
```

- Messages related to progress of InnoDB online DDL:

```
[Note] InnoDB: Online DDL : Start
[Note] InnoDB: Online DDL : Start reading clustered index of the table and
  create temporary files
[Note] InnoDB: Online DDL : End of reading clustered index of the table and
  create temporary files
[Note] InnoDB: Online DDL : Start merge-sorting index PRIMARY (1 / 3),
  estimated cost : 18.0263
[Note] InnoDB: Online DDL : merge-sorting has estimated 33 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 33 runs
[Note] InnoDB: Online DDL : merge-sorting current run 2 estimated 17 runs
[Note] InnoDB: Online DDL : merge-sorting current run 3 estimated 9 runs
[Note] InnoDB: Online DDL : merge-sorting current run 4 estimated 5 runs
[Note] InnoDB: Online DDL : merge-sorting current run 5 estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 6 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index PRIMARY (1 / 3)
[Note] InnoDB: Online DDL : Start building index PRIMARY (1 / 3),
  estimated cost : 27.0395
[Note] InnoDB: Online DDL : End of building index PRIMARY (1 / 3)
[Note] InnoDB: Online DDL : Completed
[Note] InnoDB: Online DDL : Start merge-sorting index ux1 (2 / 3),
  estimated cost : 5.7895
[Note] InnoDB: Online DDL : merge-sorting has estimated 2 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index ux1 (2 / 3)
[Note] InnoDB: Online DDL : Start building index ux1 (2 / 3),
  estimated cost : 8.6842
[Note] InnoDB: Online DDL : End of building index ux1 (2 / 3)
[Note] InnoDB: Online DDL : Completed
[Note] InnoDB: Online DDL : Start merge-sorting index ix1 (3 / 3),
  estimated cost : 6.1842
[Note] InnoDB: Online DDL : merge-sorting has estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 2 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index ix1 (3 / 3)
[Note] InnoDB: Online DDL : Start building index ix1 (3 / 3),
  estimated cost : 9.2763
[Note] InnoDB: Online DDL : End of building index ix1 (3 / 3)
[Note] InnoDB: Online DDL : Completed
```

Verbosity Level 4

If log_warnings is `4`, a couple other different kinds of warnings are printed. For example:

- Messages related to killed connections:

```
[Warning] Aborted connection 53 to db: 'db1' user:
  'user2' host: '192.168.1.50' (KILLED)
```

- Messages related to all closed connections:

```
[Warning] Aborted connection 56 to db: 'db1' user:
  'user2' host: '192.168.1.50' (CLOSE_CONNECTION)
```

- Messages related to released connections, such as when a transaction is committed and completion_type is set to `RELEASE`:

```
[Warning] Aborted connection 58 to db: 'db1' user:
  'user2' host: '192.168.1.50' (RELEASE)
```

Verbosity Level 9

If log_warnings is `9`, some **very** verbose warnings are printed. For example:

- Messages about initializing plugins:

```
[Note] Initializing built-in plugins
[Note] Initializing plugins specified on the command line
[Note] Initializing installed plugins
```

MySQL's log_error_verbosity

MariaDB does not support the log_error_verbosity system variable added in MySQL 5.7.

Format

The error log begins with a line indicating where the data is being read from, for example:

```
240919 22:58:50 mysqld_safe Starting mariadbd daemon with databases from
/home/ian/sandboxes/msb_11_7_0/data
```

Then, each item (note, warning or error) consists of a single line, containing the date (yyyy-mm-dd) and time, the thread ID, followed by the type of error (Note, Warning or Error) and the error message, for example:

```
2016-06-15 16:53:33 139651251140544 [Note] InnoDB: The InnoDB memory heap is disabled
```

Until MariaDB 10.1.4, the format only consisted of the date (yymmdd) and time, followed by the type of error (Note, Warning or Error) and the error message, for example:

```
160615 16:53:08 [Note] InnoDB: The InnoDB memory heap is disabled
```

The first item will always contain the source revision, a unique server id (from MariaDB 10.5.26, MariaDB 10.6.19, MariaDB 10.11.9, MariaDB 11.1.6, MariaDB 11.2.5, MariaDB 11.4.3, MariaDB 11.5.2, MariaDB 11.6.1) and the process_id, for example:

```
2024-09-19 22:58:50 0 [Note] Starting MariaDB 11.7.0-preview-MariaDB source revision
  7391f7143b462b29ecdaee049c5ebdfd1aefa6d7 server_uid UdJQ5BCzAQiTopMoCz3yYsfU1lA=
  as process 2307166
```

or

```
2024-05-18 16:05:33 0 [Note] Starting MariaDB 10.11.8-MariaDB source revision
  3a069644682e336e445039e48baae9693f9a08ee as process 50774
```

Formal Specification

For modern MariaDB versions (10.1.5 and later), the standard file-based error log follows this strict anatomy:

Template: `YYYY-MM-DD HH:MM:SS ThreadID [Level] Message`

Field	Component	Data Type	Description
1	Timestamp	`DateTime`	Formatted as `YYYY-MM-DD HH:MM:SS`.

Field	Component	Data Type	Description
2	Thread ID	`Unsigned Integer`	The internal connection ID. System messages use `0`.
3	Level	`String`	Enclosed in brackets. Valid values: `[Note]`, `[Warning]`, `[Error]`.
4	Message	`String`	The actual descriptive text of the event.

Deviations and Anomalies

Parsers should account for the following scenarios where the log structure may deviate:

- **Galera SST Logs:** When a Galera Cluster node performs a State Snapshot Transfer (SST), messages from external scripts (like `rsync` or `mariabackup`) are piped directly into the error log. These lines often lack the `ThreadID` and `[Level]` prefix.
- **Crash Stack Traces:** Following a server crash, MariaDB writes a multi-line stack trace. This consists of a header line followed by multiple lines of hex offsets and function names (e.g., `handle_fatal_signal (sig=11)`). These do not follow the standard single-line format.
- **Syslog Format:** If logging to syslog, the standard MariaDB prefix is replaced or preceded by the system's own header: `Month Day HH:MM:SS Hostname Ident[PID]: [Level] Message`

Rotating the Error Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the error log.

Error Messages File

Many error messages are read from an error message file that contains localized error messages. If the server can't find this file when it starts up, you might see errors like the following:

```
[ERROR] Can't find messagefile '/usr/share/errmsg.sys'
```

If this error is occurring because the file is in a custom location, you can configure this location by setting the lc_messages_dir system variable either on the command-line or in a server option group in an option file prior to starting up the server:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
```

If you want to use a different locale for error messages, you can also set the lc_messages system variable:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
lc_messages=en_US
```

See Setting the Language for Error Messages for more information.

General Query Log

The general query log is a log of every SQL query received from a client, as well as each client connect and disconnect. Since it's a record of every query received by the server, it can grow large quite quickly.

However, if you only want a record of queries that change data, it might be better to use the binary log instead. One important difference is that the binary log only logs a query when the transaction is committed by the server, but the general query log logs a query immediately when it is received by the server.

Enabling the General Query Log

The general query log is disabled by default.

To enable the general query log, set the general_log system variable to `1`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL general_log=1;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
general_log
```

Configuring the General Query Log Filename

By default, the general query log is written to `${hostname}.log` in the datadir directory. However, this can be changed.

One way to configure the general query log filename is to set the general_log_file system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL general_log_file='mariadb.log';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
general_log
general_log_file=mariadb.log
```

If it is a relative path, then the general_log_file is relative to the datadir directory.

However, the general_log_file system variable can also be an absolute path. For example:

```
[mariadb]
...
general_log
general_log_file=/var/log/mysql/mariadb.log
```

Another way to configure the general query log filename is to set the log-basename option, which configures MariaDB to use a common prefix for all log files (e.g. general query log, slow query log, error log, binary logs, etc.). The general query log filename will be built by adding a `.log` extension to this prefix. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log-basename=mariadb
general_log
```

The log-basename cannot be an absolute path. The log file name is relative to the datadir directory.

Choosing the General Query Log Output Destination

The general query log can either be written to a file on disk, or it can be written to the general_log table in the mysql database. To choose the general query log output destination, set the log_output system variable.

Writing the General Query Log to a File

The general query log is output to a file by default. However, it can be explicitly chosen by setting the log_output system variable to `FILE`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_output='FILE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
general_log
general_log_file=queries.log
```

Writing the General Query Log to a Table

The general query log can either be written to the general_log table in the mysql database by setting the log_output system variable to `TABLE`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_output='TABLE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=TABLE
general_log
```

Some rows in this table might look like this:

```
SELECT * FROM mysql.general_log\G
*************************** 1. row ***************************
  event_time: 2014-11-11 08:40:04.117177
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM test.s
*************************** 2. row ***************************
  event_time: 2014-11-11 08:40:10.501131
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM mysql.general_log
...
```

See Writing logs into tables for more information.

Formal Specification (File Format)

When the General Query Log is written to a file, it follows a positional format. For tool developers (e.g., Fluentd, Logstash), it is important to treat this log as a continuous stream of events that can contain multi-line data.

Template: `Timestamp ThreadID Command Argument`

Field	Component	Data Type	Description
1	Timestamp	`DateTime`	The time the query was received. Format varies by version (e.g., `yymmdd h:mm:ss` or ISO 8601).
2	Thread ID	`Unsigned Integer`	The standardized connection identifier. This matches the `Thread ID` field in the Error Log and Slow Query Log.
3	Command	`String`	The command type (e.g., `Connect`, `Query`, `Quit`, `Prepare`).
4	Argument	`String`	The raw SQL statement or command details.

Parsing Considerations for Tool Developers

- **Multi-line SQL:** The `Argument` field contains the literal SQL query received by the server. Because SQL queries often contain newlines, a single log entry can span multiple lines. Parsers must be configured to handle multiline events, typically by identifying a new record when a line begins with a valid timestamp.
